1.5 Performance Outline

Table 1.5.1 is a performance outline.

Table 1.5.1 Performance outline

| Item | | Performance |
|-------------------------------------|---|---|
| Number of basic instructions | | 91 instructions |
| Shortest instruction execution time | | 100 ns(f(XIN)=10 MHz) |
| Memory size | ROM | 192K bytes |
| | RAM | 5K bytes |
| | OSD ROM | 61K bytes |
| | OSD RAM | 2.2K bytes |
| I/O port | P0, P2 to P10 | 8 bits X 3, 5 bits X 1, 4 bits X 2, 3 bits X 2, 2 bits X 1, 1 bit X 1 |
| Multifunction timer | TA0, TA1, TA2, TA3, TA4 | 16 bits X 5 |
| | TB0, TB1, TB2 | 16 bits X 3 |
| Serial I/O | UART0 | 1 unit: UART or clock synchronous |
| | UART2 | 1 unit: UART or clock synchronous |
| | Multi-master I ² C-BUS interface 0 | 1 unit (2 channels) |
| | Multi-master I ² C-BUS interface 1 | 1 unit (1 channels) |
| A-D converter | | 8 bits X 6 channels |
| D-A converter | | 8 bits X 2 channels |
| DMAC | | 2 channels (trigger: 23 sources) |
| OSD function | | Triple layer, 890 kinds of fonts, 42 character X 16 lines |
| Data slicer | | 32-bit buffer |
| HSYNC counter | | 8 bits X 2 channels |
| Watchdog timer | | 15 bits X 1 (with prescaler) |
| Interrupt | | 21 internal and 3 external sources, 4 software sources, 7 levels |
| Clock generating circuit | | 2 built-in clock generation circuits |
| Power source voltage | | 4.5 V to 5.5V (f(XIN) = 10 MHz) |
| Power consumption | | 250 mW |
| I/O characteristics | I/O withstand voltage | 5 V |
| | Output current | 5 mA |
| Operating ambient temperature | | -10 °C to 70 °C |
| Device configuration | | CMOS high performance silicon gate |
| Package | | 64-pin plastic molded SDIP |

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

Currently supported products are listed below.

Table 1.5.2 List of supported products

| Type No | ROM capacity | RAM capacity | Package type | Remarks |
|----------------|--------------|--------------|--------------|-----------------------|
| M306V5ME-XXXSP | 192K bytes | 5K bytes | 64P4B | Mask ROM version |
| M306V5EESP | 192K bytes | 5K bytes | 64P4B | One Time PROM version |
| M306V5EESS | 192K bytes | 5K bytes | 64S1B | EPROM version |

Note: Since EPROM version is for development support tool (for evaluation), do not use for mass production.

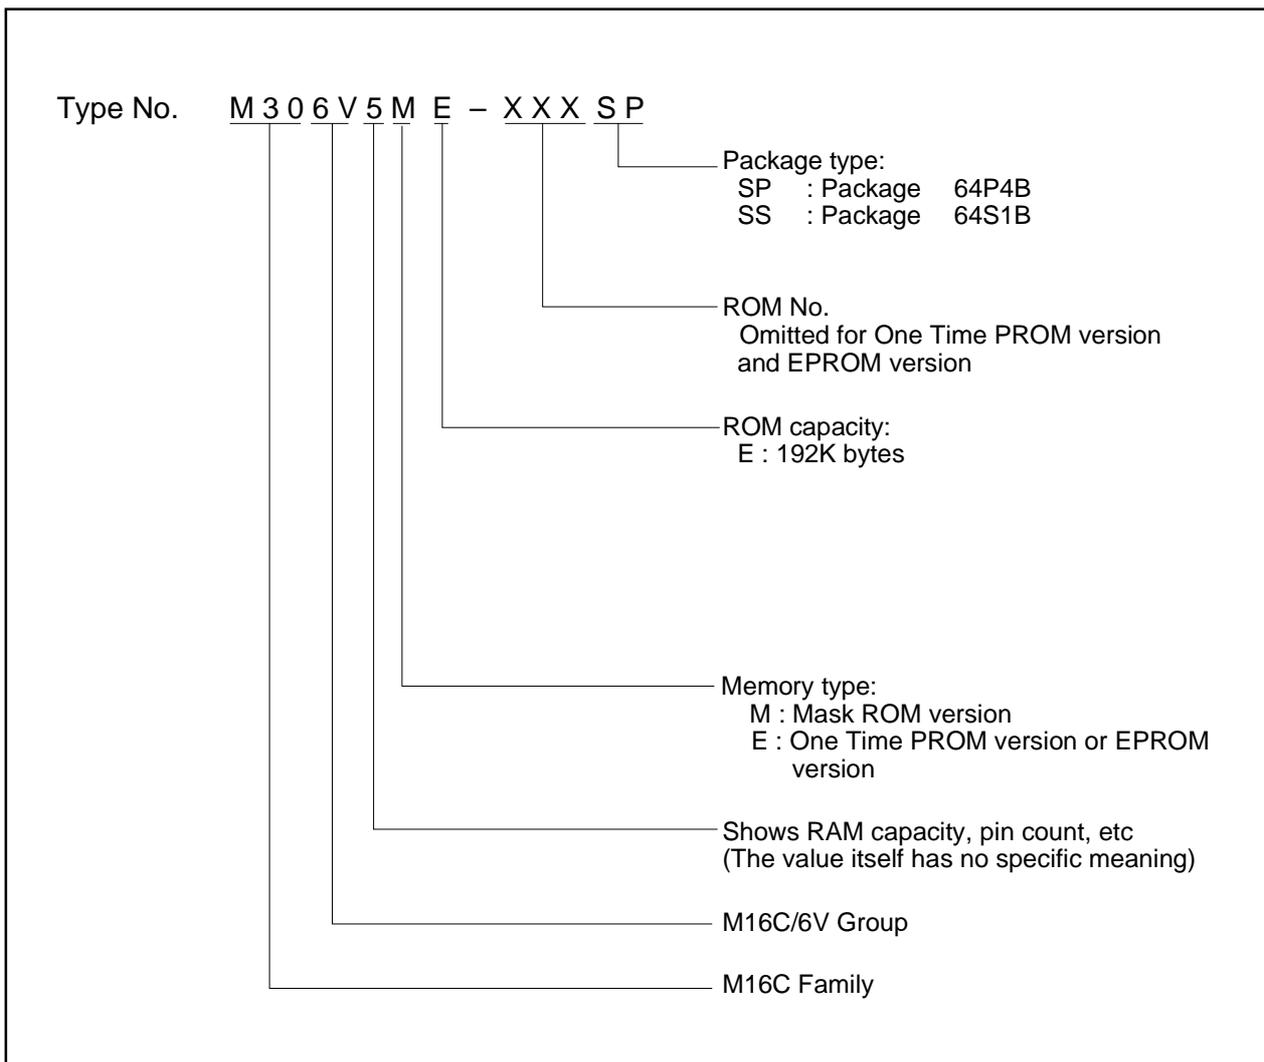

Figure 1.5.1 Type No., memory size, and package

1.5.1 As For M16C/6V (64-Pin Version) Group

M16C/6V (64-pin version) group is packaged in a 64-pin plastic molded SDIP. Note that the number of pins is reduced when it is compared with a 100-pin package product.

- (1) M16C/6V (64-pin version) group supports only the shingle-chip mode. It does not support the memory expansion and the microprocessor modes.
- (2) Be sure to initialize in the sequence below immediately after reset release.
 - ① Set OSD reserved register i ($i = 1$ to 4) to the specified values.
 - ② Set each reserved bit of the port P_i direction register, the port P_i register, and pull-up control register i to the specified values.
 - ③ Set port reserved register i ($i = 1$ to 3) to the specified values.
 - ④ Set other reserved registers and each reserved bit of other registers to the specified values.

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

Table 1.5.3 Pin description (1)

| Pin name | Signal name | I/O type | Function |
|---------------------------|-----------------------------|-----------------|---|
| Vcc, Vss | Power supply input | | Supply 4.5 V to 5.5 V to the Vcc pin. Supply 0 V to the Vss pin. |
| CNVss | CNVss | Input | Connect this pin to the Vss pin. |
| $\overline{\text{RESET}}$ | Reset input | Input | A "L" on this input resets the microcomputer. |
| XIN XOUT | Clock input Clock output | Input Output | These pins are provided for the main clock generating circuit. Connect a ceramic resonator or crystal between the XIN and the XOUT pins. To use an externally derived clock, input it to the XIN pin and leave the XOUT pin open. |
| AVcc | Analog power supply input | | This pin is a power supply input for the A-D converter. Connect this pin to Vcc. |
| P00 to P07 | I/O port P0 | Input/output | This is an 8-bit CMOS I/O port. It has an input/output port direction register that allows the user to set each pin for input or output individually. When set for input, the user can specify in units of four bits via software whether or not they are tied to a pull-up resistor. |
| P20 to P27 | I/O port P2 | Input/output | This is an 8-bit I/O port equivalent to P0. |
| P30 to P37 | I/O port P3 | Input/output | This is an 8-bit I/O port equivalent to P0. Pins in this port function as external interrupt pin, HSYNC counter I/O pins, and A-D converter input pins as selected by software. |
| P40 to P43 | I/O port P4 | Input/output | This is an 8-bit I/O port equivalent to P0. Pins in this port function as A-D converter input pins as selected by software. |
| P50, P52, P53, P55 | I/O port P5 | Input/output | This is a 4-bit I/O port equivalent to P0. P57 in this port functions as UART0 I/O pin as selected by software. |
| P62, P63, P67 | I/O port P6 | Input/output | This is a 3-bit I/O port equivalent to P0. Pins in this port also function as UART0 and multi-master I ² C-BUS interface 0 I/O pins as selected by software. |
| P70 to P72, P74, P76 | I/O port P7 | Input/output | This is a 5-bit I/O port equivalent to P0 (P70 and P71 are N-channel open-drain output). Pins in this port also function as timers A2 and A3, UART2, multi-master I ² C-BUS interface 0 I/O pins as selected by software. |
| P82 | I/O port P8 | Input/output | P82 is I/O port with the same functions as P0. P82 can be made to function as the I/O pin for the input pins for external interrupts as selected by software. |
| P90, P93, P94 | I/O port P9 | Input/output | This is an 3-bit I/O port equivalent to P0. Pins in this port also function as Timer B0 input pin, D-A converter output pins, and multi-master I ² C-BUS interface 1 I/O pins as selected by software. |

M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

Table 1.5.4 Pin description (continued) (2)

| Pin name | Signal name | I/O type | Function |
|-------------------------------------|----------------------|--------------|---|
| P10 ₀ , P10 ₁ | I/O port P10 | Input/output | This is a 2-bit I/O port equivalent to P0. Pins in this port also function as a input pins for OSD function as selected bysoftware. |
| R, G, B | OSD output | Output | These are OSD output pins (analog output). |
| OUT1, OUT2 | OSD output | Output | These are OSD output pins (digital output). |
| OSC1 | Clock input for OSD | Input | This is an OSD clock input pin. |
| OSC2 | Clock output for OSD | Output | This is an OSD clock output pin. |
| CVIN | I/O for data slicer | Input | Input composite video signal through a capacitor. |
| VHOLD | | Input | Connect a capacitor between VHOLD and Vss. |
| HLF | | Input/output | Connect a filter using of a capacitor and a resistor between HLF and Vss. |
| TVSETB | Test input | Input | This is a test input pin. Fix it to "L." |

2. OPERATION OF FUNCTIONAL BLOKS

This microcomputer accommodates certain units in a single chip. These units include ROM and RAM to store instructions and data and the central processing unit (CPU) to execute arithmetic/logic operations. Also included are peripheral units such as timers, serial I/O, D-A converter, DMAC, OSD circuit, data slicer, A-D converter, and I/O ports.

The following explains each unit.

2.1 Memory

Figure 2.1.1 is a memory map. The address space extends the 1M bytes from address 00000₁₆ to FFFFF₁₆. From FFFFF₁₆ down is ROM. There is 192K bytes of internal ROM from D0000₁₆ to FFFFF₁₆. The vector table for fixed interrupts such as the reset mapped to FFFDC₁₆ to FFFFF₁₆. The starting address of the interrupt routine is stored here. The address of the vector table for timer interrupts, etc., can be set as desired using the internal register (INTB). See the section on interrupts for details.

5K bytes of internal RAM is mapped to the space from 02C00₁₆ to 03FFF₁₆. In addition to storing data, the RAM also stores the stack used when calling subroutines and when interrupts are generated.

The SFR area is mapped to 00000₁₆ to 003FF₁₆. This area accommodates the control registers for peripheral devices such as I/O ports, A-D converter, serial I/O, and timers, etc. Figures 2.1.2 to 2.1.5 are location of peripheral unit control registers. Any part of the SFR area that is not occupied is reserved and cannot be used for other purposes.

The special page vector table is mapped to FFE00₁₆ to FFFDB₁₆. If the starting addresses of subroutines or the destination addresses of jumps are stored here, subroutine call instructions and jump instructions can be used as 2-byte instructions, reducing the number of program steps.

Figure 2.1.5 Location of peripheral unit control registers (4)

2.2 Central Processing Unit (CPU)

The CPU has a total of 13 registers shown in Figure 2.2.1. Seven of these registers (R0, R1, R2, R3, A0, A1, and FB) come in two sets; therefore, these have two register banks.

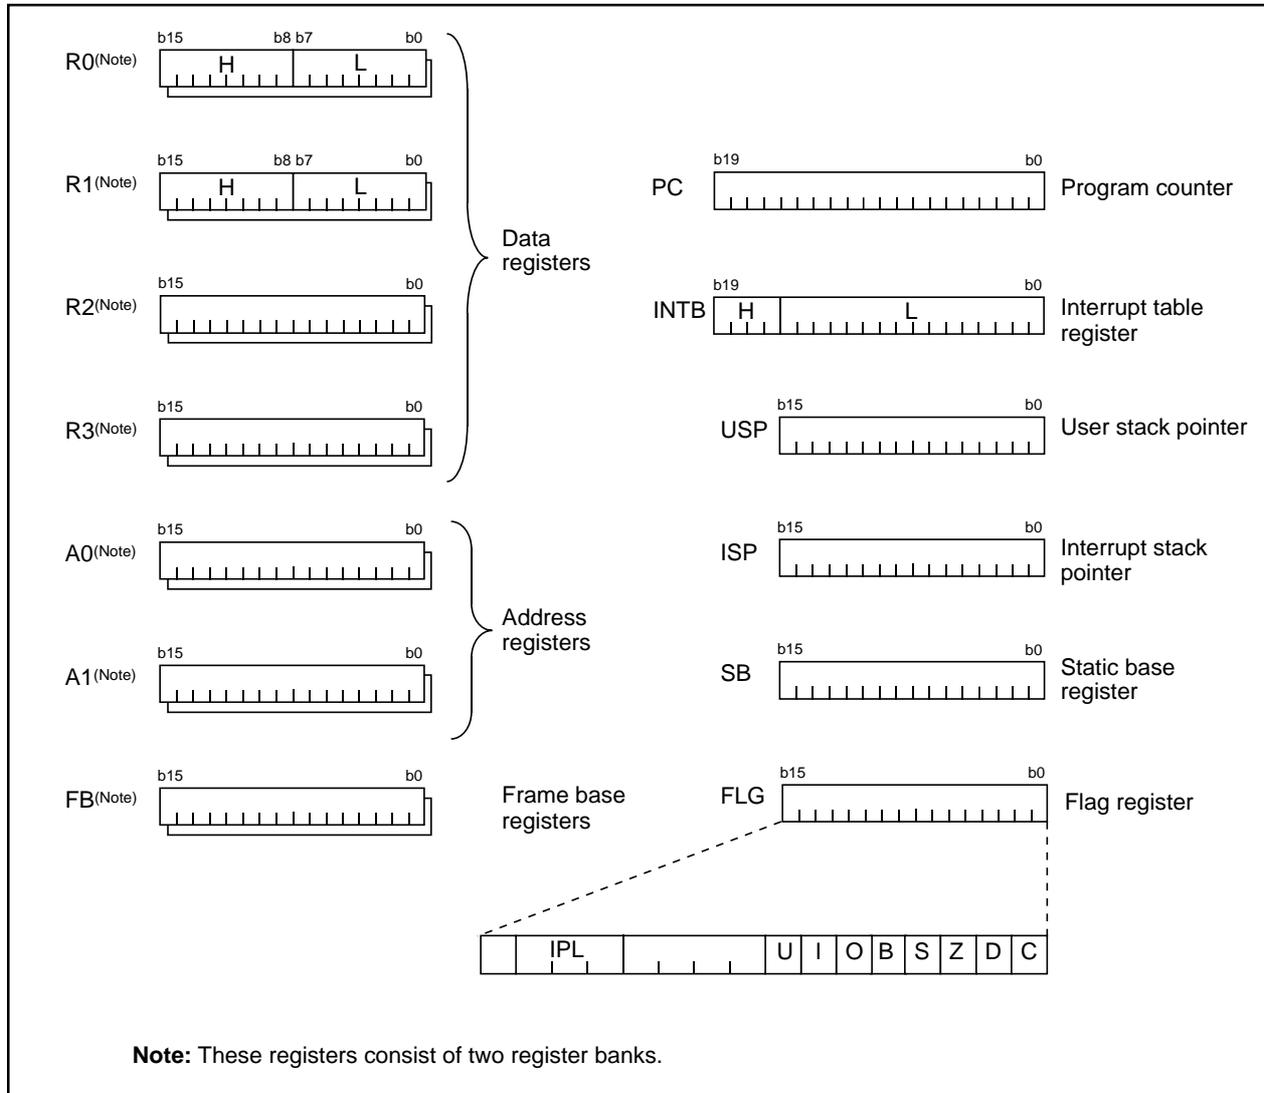

Figure 2.2.1 Central processing unit register

2.2.1 Data Registers (R0, R0H, R0L, R1, R1H, R1L, R2, and R3)

Data registers (R0, R1, R2, and R3) are configured with 16 bits, and are used primarily for transfer and arithmetic/logic operations.

Registers R0 and R1 each can be used as separate 8-bit data registers, high-order bits as (R0H/R1H), and low-order bits as (R0L/R1L). In some instructions, registers R2 and R0, as well as R3 and R1 can use as 32-bit data registers (R2R0/R3R1).

2.2.2 Address Registers (A0 and A1)

Address registers (A0 and A1) are configured with 16 bits, and have functions equivalent to those of data registers. These registers can also be used for address register indirect addressing and address register relative addressing.

In some instructions, registers A1 and A0 can be combined for use as a 32-bit address register (A1A0).

2.2.3 Frame Base Register (FB)

Frame base register (FB) is configured with 16 bits, and is used for FB relative addressing.

2.2.4 Program Counter (PC)

Program counter (PC) is configured with 20 bits, indicating the address of an instruction to be executed.

2.2.5 Interrupt Table Register (INTB)

Interrupt table register (INTB) is configured with 20 bits, indicating the start address of an interrupt vector table.

2.2.6 Stack Pointer (USP/ISP)

Stack pointer comes in two types: user stack pointer (USP) and interrupt stack pointer (ISP), each configured with 16 bits.

Your desired type of stack pointer (USP or ISP) can be selected by a stack pointer select flag (U flag).

This flag is located at the position of bit 7 in the flag register (FLG).

2.2.7 Static Base Register (SB)

Static base register (SB) is configured with 16 bits, and is used for SB relative addressing.

2.2.8 Flag Register (FLG)

Flag register (FLG) is configured with 11 bits, each bit is used as a flag. Figure 2.2.2 shows the flag register (FLG). The following explains the function of each flag:

- **Bit 0: Carry flag (C flag)**

This flag retains a carry, borrow, or shift-out bit that has occurred in the arithmetic/logic unit.

- **Bit 1: Debug flag (D flag)**

This flag enables a single-step interrupt.

When this flag is "1", a single-step interrupt is generated after instruction execution. This flag is cleared to "0" when the interrupt is acknowledged.

- **Bit 2: Zero flag (Z flag)**

This flag is set to "1" when an arithmetic operation resulted in 0; otherwise, cleared to "0".

- **Bit 3: Sign flag (S flag)**

This flag is set to "1" when an arithmetic operation resulted in a negative value; otherwise, cleared to "0".

- **Bit 4: Register bank select flag (B flag)**

This flag chooses a register bank. Register bank 0 is selected when this flag is "0"; register bank 1 is selected when this flag is "1".

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

• **Bit 5: Overflow flag (O flag)**

This flag is set to “1” when an arithmetic operation resulted in overflow; otherwise, cleared to “0”.

• **Bit 6: Interrupt enable flag (I flag)**

This flag enables a maskable interrupt.

An interrupt is disabled when this flag is “0”, and is enabled when this flag is “1”. This flag is cleared to “0” when the interrupt is acknowledged.

• **Bit 7: Stack pointer select flag (U flag)**

Interrupt stack pointer (ISP) is selected when this flag is “0” ; user stack pointer (USP) is selected when this flag is “1”.

This flag is cleared to “0” when a hardware interrupt is acknowledged or an INT instruction of software interrupt Nos. 0 to 31 is executed.

• **Bits 8 to 11: Reserved area**

• **Bits 12 to 14: Processor interrupt priority level (IPL)**

Processor interrupt priority level (IPL) is configured with three bits, for specification of up to eight processor interrupt priority levels from level 0 to level 7.

If a requested interrupt has priority greater than the processor interrupt priority level (IPL), the interrupt is enabled.

• **Bit 15: Reserved area**

The C, Z, S, and O flags are changed when instructions are executed. See the software manual for details.

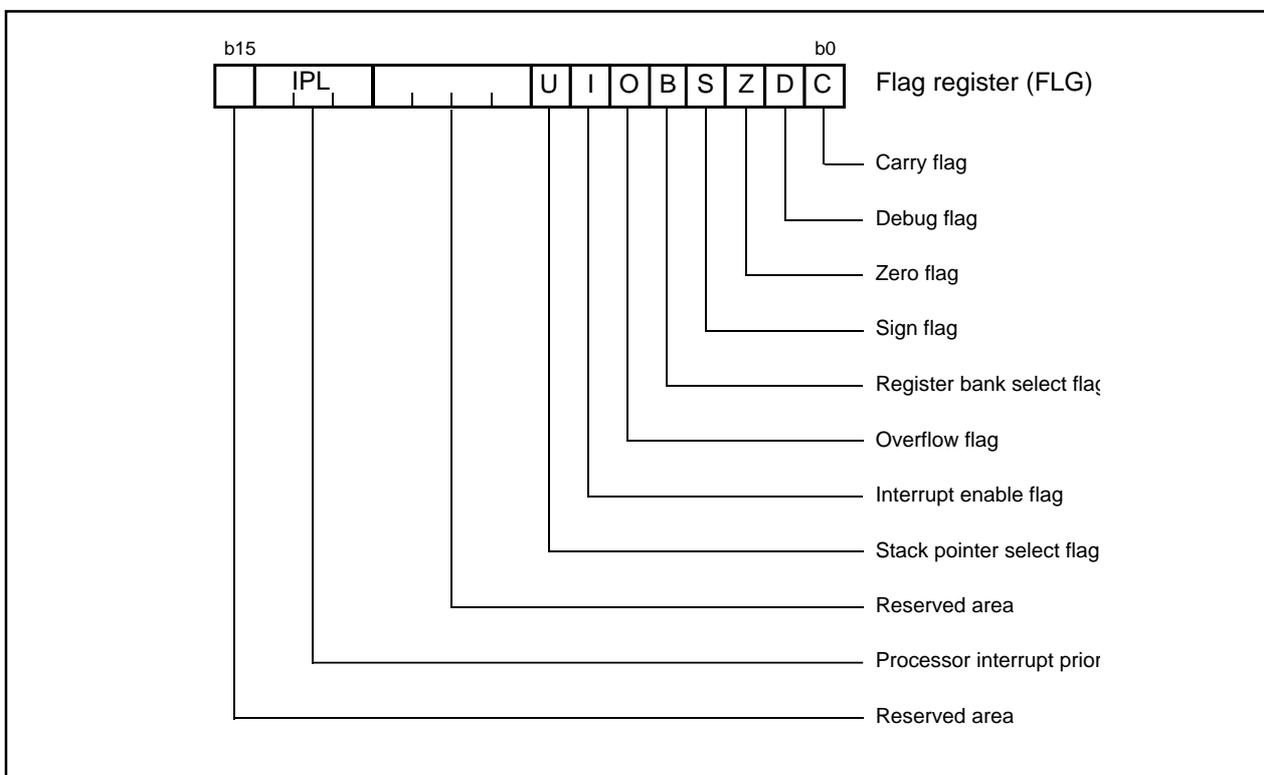

Figure 2.2.2 Flag register (FLG)

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.3 Reset

There are two kinds of resets; hardware and software. In both cases, operation is the same after the reset. (See "Software Reset" for details of software resets.) This section explains on hardware resets.

When the supply voltage is in the range where operation is guaranteed, a reset is effected by holding the reset pin level "L" (0.2V_{CC} max.) for at least 20 cycles. When the reset pin level is then returned to the "H" level while main clock is stable, the reset status is cancelled and program execution resumes from the address in the reset vector table.

Figure 2.3.1 shows the example reset circuit. Figure 2.3.2 shows the reset sequence.

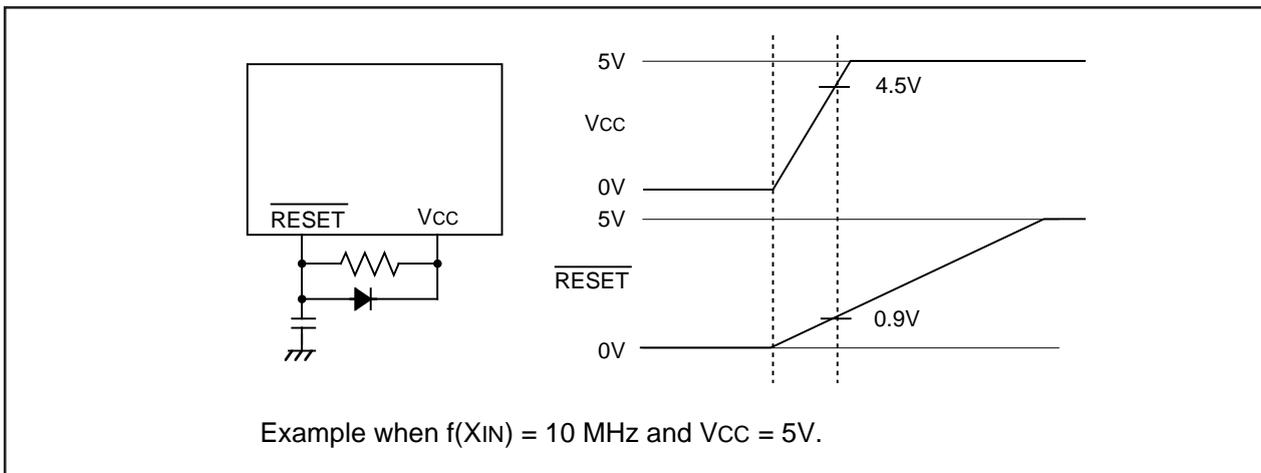

Figure 2.3.1 Example reset circuit

2.3.1 Software Reset

Writing "1" to bit 3 of the processor mode register 0 (address 000416) applies a (software) reset to the microcomputer. A software reset has almost the same effect as a hardware reset. The contents of internal RAM are preserved.

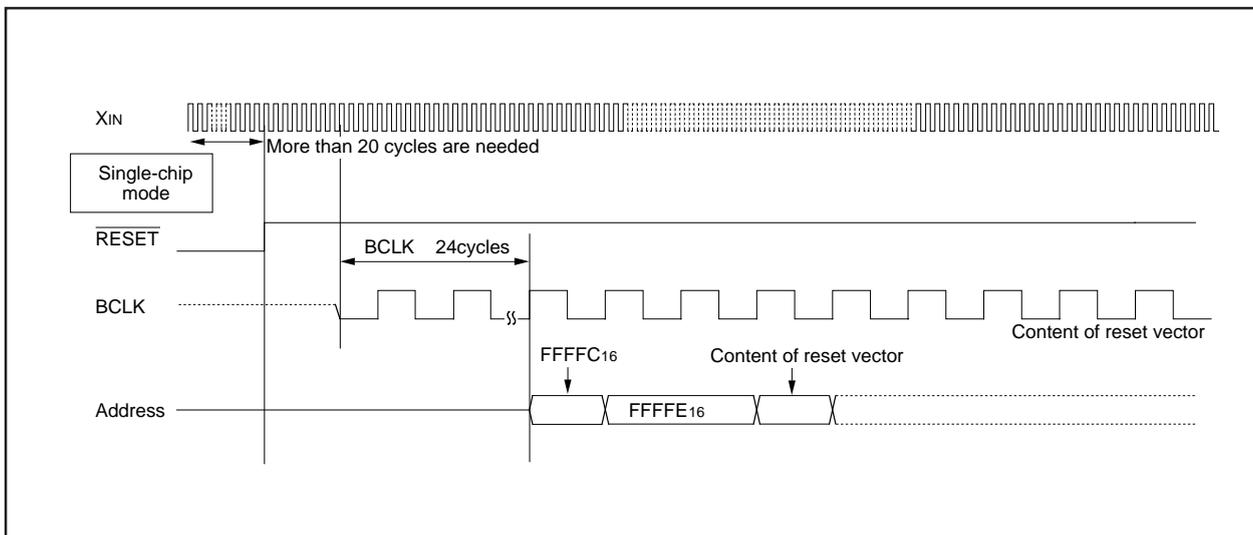

Figure 2.3.2 Reset sequence

2.4 Single-chip Mode

This microcomputer supports single-chip mode only.

In single-chip mode, only internal memory space (SFR, OSD RAM, internal RAM, and internal ROM) can be accessed. Ports P0, P2 to P10 can be used as programmable I/O ports or as I/O ports for the internal peripheral functions.

Figure 2.4.1 shows the processor mode register 0 and Figure 2.4.2 shows the processor mode register 1. Figure 2.4.3 shows the memory map.

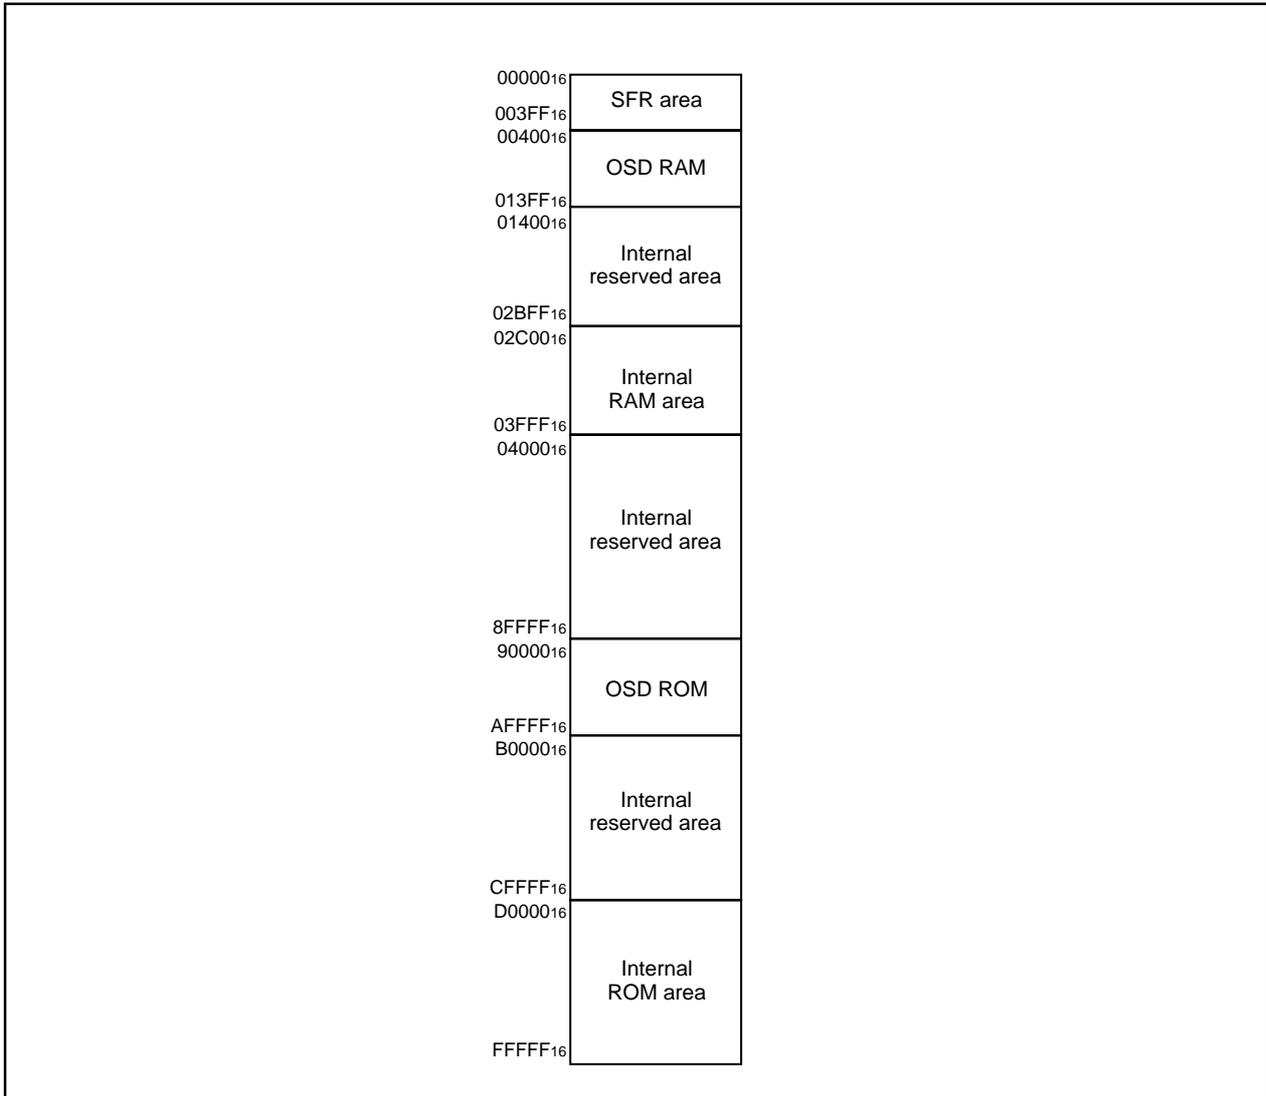

Figure 2.4.3 Memory map in single-chip mode

2.4.1 Software Wait

A software wait can be inserted by setting the wait bit (bit 7) of processor mode register 1 (address 0005₁₆).

A software wait is inserted in the internal ROM/RAM area by setting the wait bit of the processor mode register 1. When set to "0", each bus cycle is executed in one BCLK cycle. When set to "1", each bus cycle is executed in two BCLK cycles. After the microcomputer has been reset, this bit defaults to "0".

The SFR area and the OSD RAM area is always accessed in two BCLK cycles regardless of the setting of these control bits.

Table 2.4.1 shows the software wait and bus cycles. Figure 2.4.4 shows example bus timing when using software waits.

Table 2.4.1 Software waits and bus cycles

| Area | Wait bit | Bus cycle |
|---------------------|----------|---------------|
| SFR/ OSD RAM | Invalid | 2 BCLK cycles |
| Internal ROM/RAM | 0 | 1 BCLK cycle |
| | 1 | 2 BCLK cycles |

2.5 Clock Generating Circuit

The clock generating circuit contains each oscillator circuit that supplies the operating clock sources to the CPU and internal peripheral units and that supplies the operating clock source to OSD.

Table 2.5.1. Clock oscillation circuits

| | Main clock oscillation circuit | OSD oscillation circuit |
|---|---|---|
| Use of clock | <ul style="list-style-type: none"> • CPU's operating clock source • Internal peripheral units' operating clock source | <ul style="list-style-type: none"> • OSD's operating clock source |
| Usable oscillator | <ul style="list-style-type: none"> • Ceramic resonator (or quartz-crystal oscillator) | <ul style="list-style-type: none"> • Ceramic resonator (or quartz-crystal oscillator) • LC oscillator |
| Pins to connect oscillator | XIN, XOUT | OSC1, OSC2 |
| Oscillation stop/restart function | Available | / |
| Oscillator status immediately after reset | Oscillating | |
| Other | Externally derived clock can be input | |

2.5.1 Example of Oscillator Circuit

Figure 2.5.1 shows some examples of the main clock circuit, one using an oscillator connected to the circuit, and the other one using an externally derived clock for input. Circuit constants in Figure 2.5.1 vary with each oscillator used. Use the values recommended by the manufacturer of your oscillator.

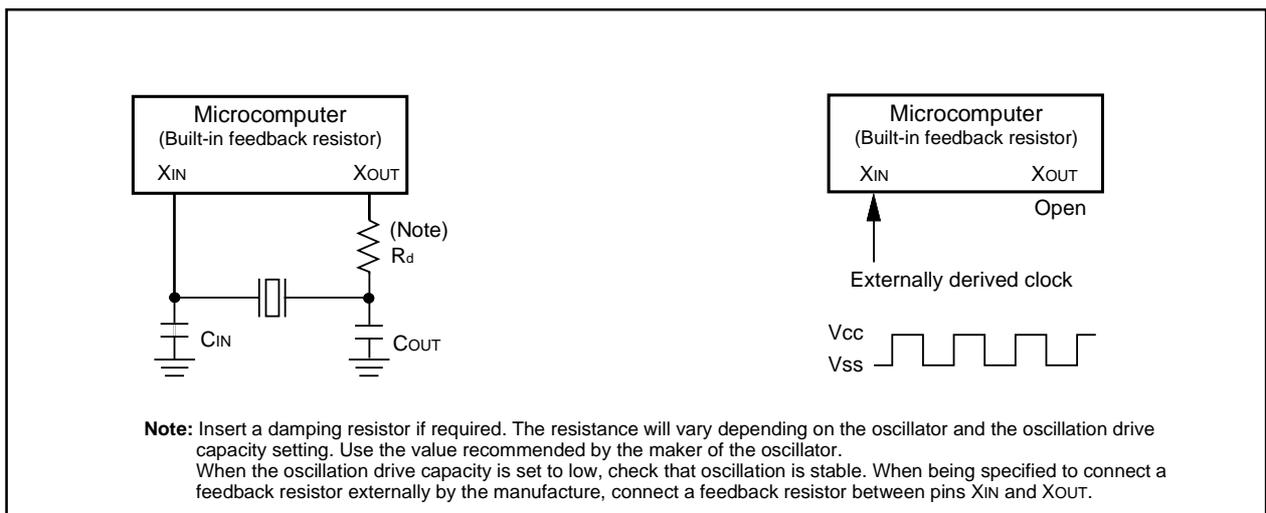

Figure 2.5.1 Examples of main clock

M306V5ME-XXXSP M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.5.2 OSD Oscillation Circuit

The OSD clock oscillation circuit can obtain simply a clock for OSD by connecting an LC oscillator or a ceramic resonator (or a quartz-crystal oscillator) across the pins OSC1 and OSC2. Which of LC oscillator or a ceramic resonator (or a quartz-crystal oscillator) is selected by setting bits 1 and 2 of the clock control register (address 020516).

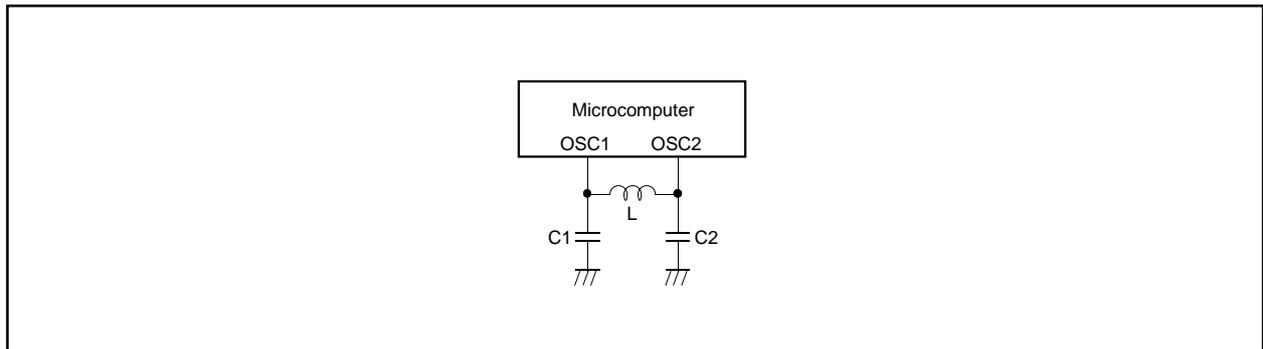

Figure 2.5.2 OSD clock connection example

2.5.3 Clock Control

Figure 2.5.3 shows the block diagram of the main clock generating circuit.

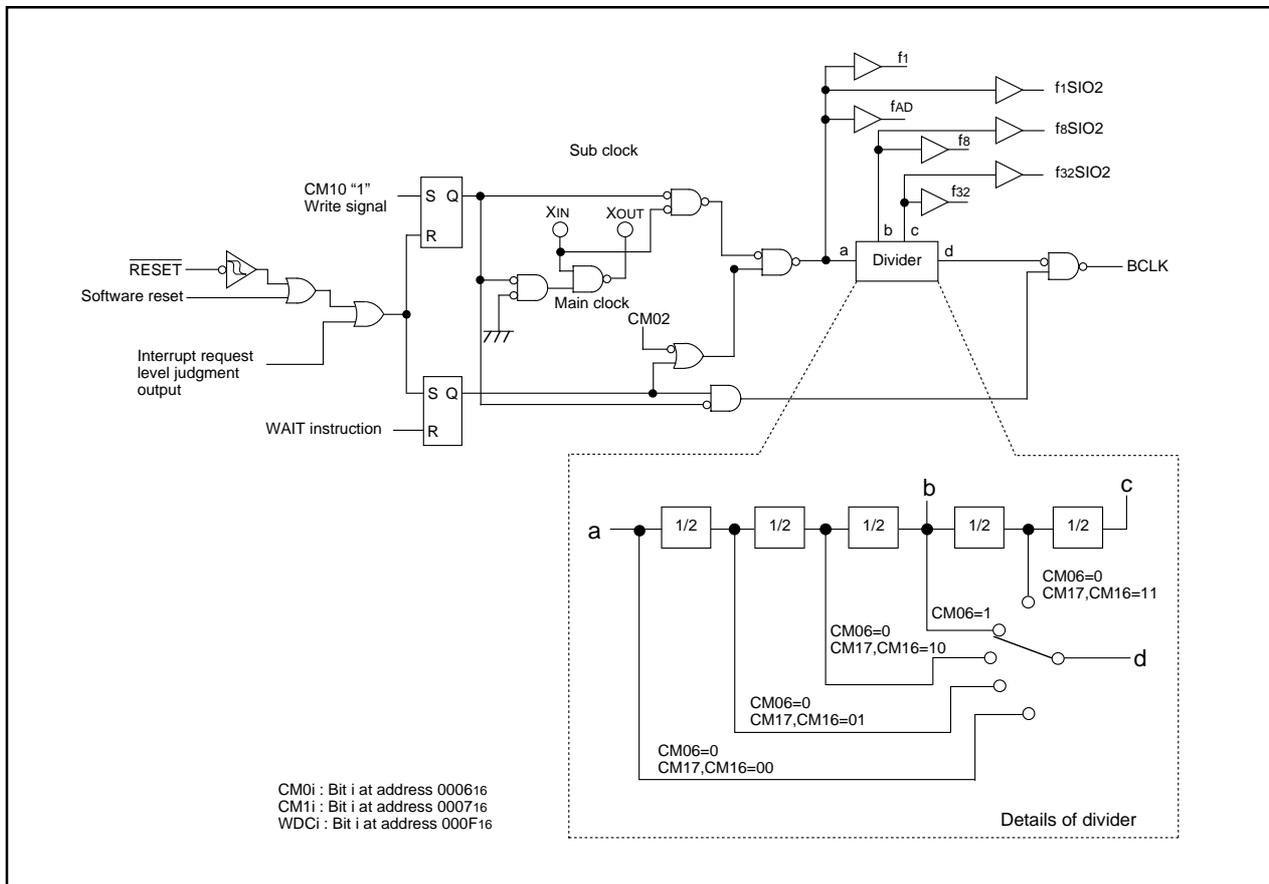

Figure 2.5.3 Clock generating circuit

The following paragraphs describes the clocks generated by the clock generating circuit.

(1) Main clock

The main clock is generated by the main clock oscillation circuit. After a reset, the clock is divided by 8 to the BCLK. The clock can be stopped using the main clock stop bit (bit 5 at address 000616).

After the oscillation of the main clock oscillation circuit has stabilized, the drive capacity of the main clock oscillation circuit can be reduced using the XIN-XOUT drive capacity select bit (bit 5 at address 000716). Reducing the drive capacity of the main clock oscillation circuit reduces the power dissipation. This bit changes to "1" when shifting from high-speed/medium-speed mode to stop mode and at a reset.

(2) BCLK

The internal clock ϕ is the clock that drives the CPU, and is the clock derived by dividing the main clock by 1, 2, 4, 8, or 16. The BCLK is derived by dividing the main clock by 8 after a reset.

The main clock division select bit 0 (bit 6 at address 000616) changes to "1" when shifting from high-speed/medium-speed to stop mode and at reset.

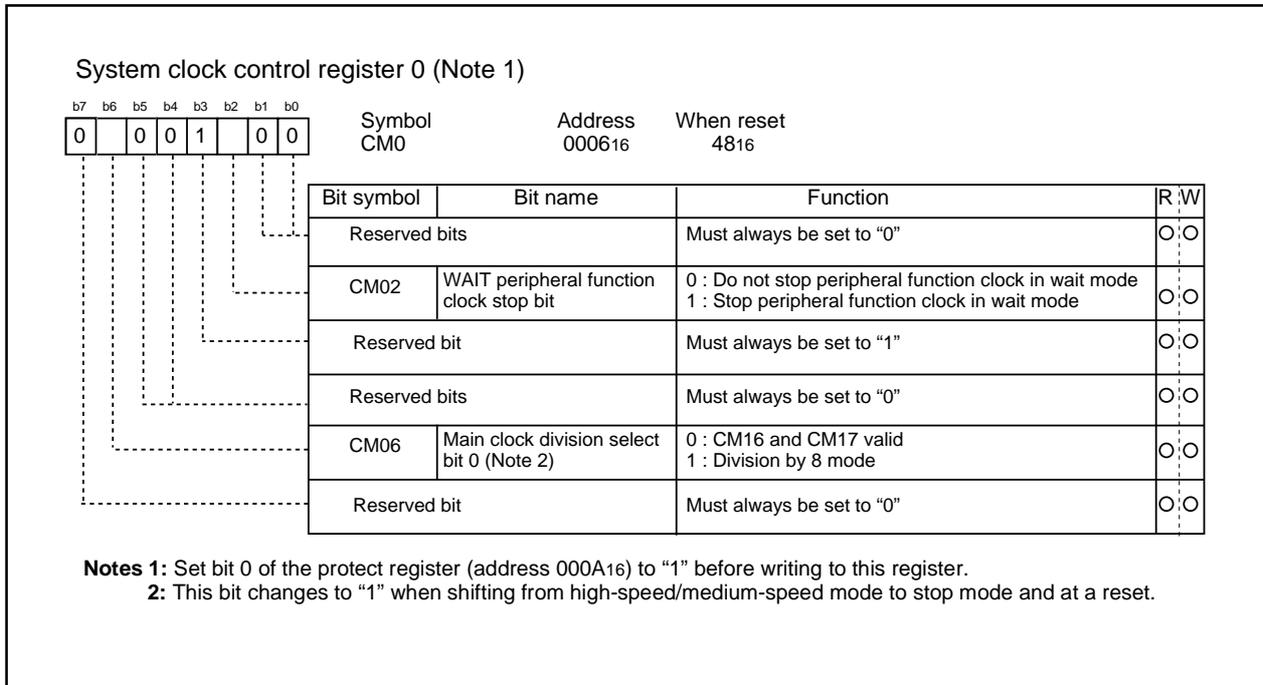

(3) Peripheral function clock (f1, f8, f32, f1SIO2, f8SIO2, f32SIO2, fAD)

The clock for the peripheral devices is derived by dividing the main clock by 1, 8 or 32. The peripheral function clock is stopped by stopping the main clock or by setting the WAIT peripheral function clock stop bit (bit 2 at 000616) to "1" and then executing a WAIT instruction.

and ON-SCREEN DISPLAY CONTROLLER

2.5.4 Stop Mode

Writing "1" to the all-clock stop control bit (bit 0 at address 000716) stops all oscillation and the microcomputer enters stop mode. In stop mode, the content of the internal RAM is retained provided that VCC remains above 4.5V.

Because the oscillation, BCLK, f1 to f32, f1SIO2 to f32SIO2, and fAD stops in stop mode, peripheral functions such as the A-D converter and watchdog timer do not function. However, timer B operates provided that the event counter mode is set to an external pulse, and UARTi (i = 0, 2) functions provided an external clock is selected. Table 2.5.2 shows the status of the ports in stop mode.

Stop mode is cancelled by a hardware reset or an interrupt. If an interrupt is to be used to cancel stop mode, that interrupt must first have been enabled. If returning by an interrupt, that interrupt routine is executed.

When shifting from high-speed/medium-speed mode to stop mode and at a reset, the main clock division select bit 0 (bit 6 at address 000616) is set to "1." When shifting from low-speed/low power dissipation mode to stop mode, the value before stop mode is retained.

Table 2.5.2 Port status during stop mode

| Pin | State |
|------|---------------------------------|
| Port | Retains status before stop mode |

2.5.5 Wait Mode

When a WAIT instruction is executed, the BCLK stops and the microcomputer enters the wait mode. In this mode, oscillation continues but the BCLK and watchdog timer stop. Writing "1" to the WAIT peripheral function clock stop bit and executing a WAIT instruction stops the clock being supplied to the internal peripheral functions, allowing power dissipation to be reduced. Table 2.5.3 shows the status of the ports in wait mode.

Wait mode is cancelled by a hardware reset or an interrupt. If an interrupt is used to cancel wait mode, the microcomputer restarts from the interrupt routine using as BCLK, the clock that had been selected when the WAIT instruction was executed.

Table 2.5.3 Port status during wait mode

| Pin | State |
|------|---------------------------------|
| Port | Retains status before wait mode |

2.5.6 Status Transition of BCLK

Power dissipation can be reduced and low-voltage operation achieved by changing the count source for BCLK. Table 2.5.4 shows the operating modes corresponding to the settings of system clock control registers 0 and 1.

After a reset, operation defaults to division by 8 mode. When shifting to stop mode, the main clock division select bit 0 (bit 6 at address 000616) is set to "1". The following shows the operational modes of internal clock ϕ .

(1) Division by 2 mode

The main clock is divided by 2 to obtain the BCLK.

(2) Division by 4 mode

The main clock is divided by 4 to obtain the BCLK.

(3) Division by 8 mode

The main clock is divided by 8 to obtain the BCLK. Note that oscillation of the main clock must have stabilized before transferring from this mode to another mode.

(4) Division by 16 mode

The main clock is divided by 16 to obtain the BCLK.

(5) No-division mode

The main clock is used as the BCLK.

Table 2.5.4 Operating modes dictated by settings of system clock control registers 0 and 1

| CM17 | CM16 | CM06 | CM04 | Operating mode of BCLK |
|---------|---------|------|---------|------------------------|
| 0 | 1 | 0 | Invalid | Division by 2 mode |
| 1 | 0 | 0 | Invalid | Division by 4 mode |
| Invalid | Invalid | 1 | Invalid | Division by 8 mode |
| 1 | 1 | 0 | Invalid | Division by 16 mode |
| 0 | 0 | 0 | Invalid | No-division mode |

2.5.7 Power Control

The following is a description of the three available power control modes:

Modes

Power control is available in three modes.

(1) Normal operation mode

■ High-speed mode

Divide-by-1 frequency of the main clock becomes the BCLK. The CPU operates with the internal clock selected. Each peripheral function operates according to its assigned clock.

■ Medium-speed mode

Divide-by-2, divide-by-4, divide-by-8, or divide-by-16 frequency of the main clock becomes the BCLK. The CPU operates according to the internal clock selected. Each peripheral function operates according to its assigned clock.

(2) Wait mode

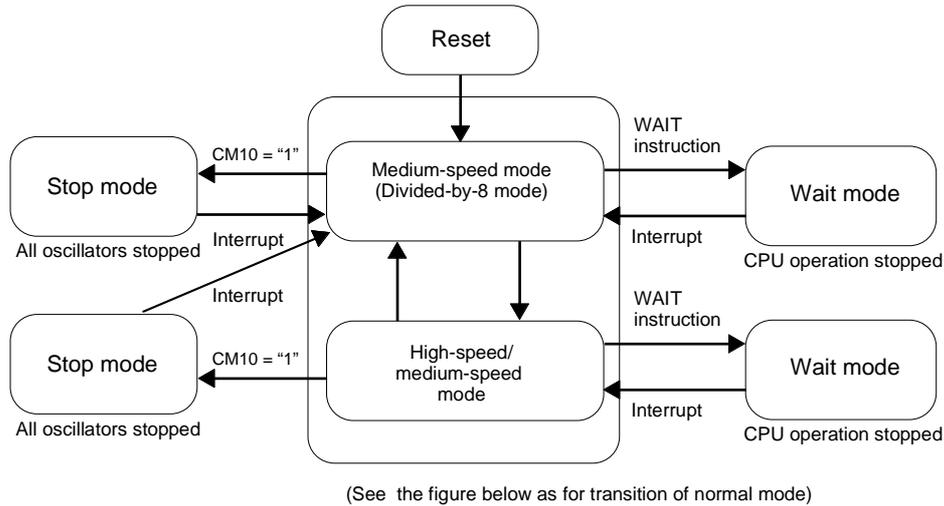

The CPU operation is stopped. The oscillators do not stop.

(3) Stop mode

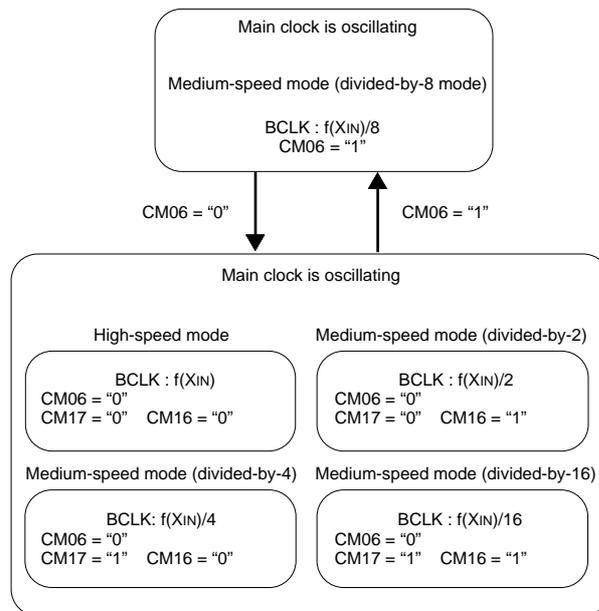

All oscillators stop. The CPU and all built-in peripheral functions stop. This mode, among the three modes listed here, is the most effective in decreasing power consumption.

Figure 2.5.6 is the state transition diagram of the above modes.

Transition of stop mode, wait mode

Transition of normal mode

- Notes 1:** Switch clocks after oscillation of main clock is sufficiently stable.
2: Change CM06 after changing CM17 and CM16.
3: Transit in accordance with arrows.

Figure 2.5.6 State transition diagram of Power control mode

2.6 Protection

The protection function is provided so that the values in important registers cannot be changed in the event that the program runs out of control. Figure 2.6.1 shows the protect register. The values in the processor mode register 0 (address 0004₁₆), processor mode register 1 (address 0005₁₆), system clock control register 0 (address 0006₁₆), system clock control register 1 (address 0007₁₆) and port P9 direction register (address 03F3₁₆) can only be changed when the respective bit in the protect register is set to "1". Therefore, important outputs can be allocated to port P9.

If, after "1" (write-enabled) has been written to the port P9 direction register write-enable bit (bit 2 at address 000A₁₆), a value is written to any address, the bit automatically reverts to "0" (write-inhibited). However, the system clock control registers 0 and 1 write-enable bit (bit 0 at 000A₁₆) and processor mode register 0 and 1 write-enable bit (bit 1 at 000A₁₆) do not automatically return to "0" after a value has been written to an address. The program must therefore be written to return these bits to "0".

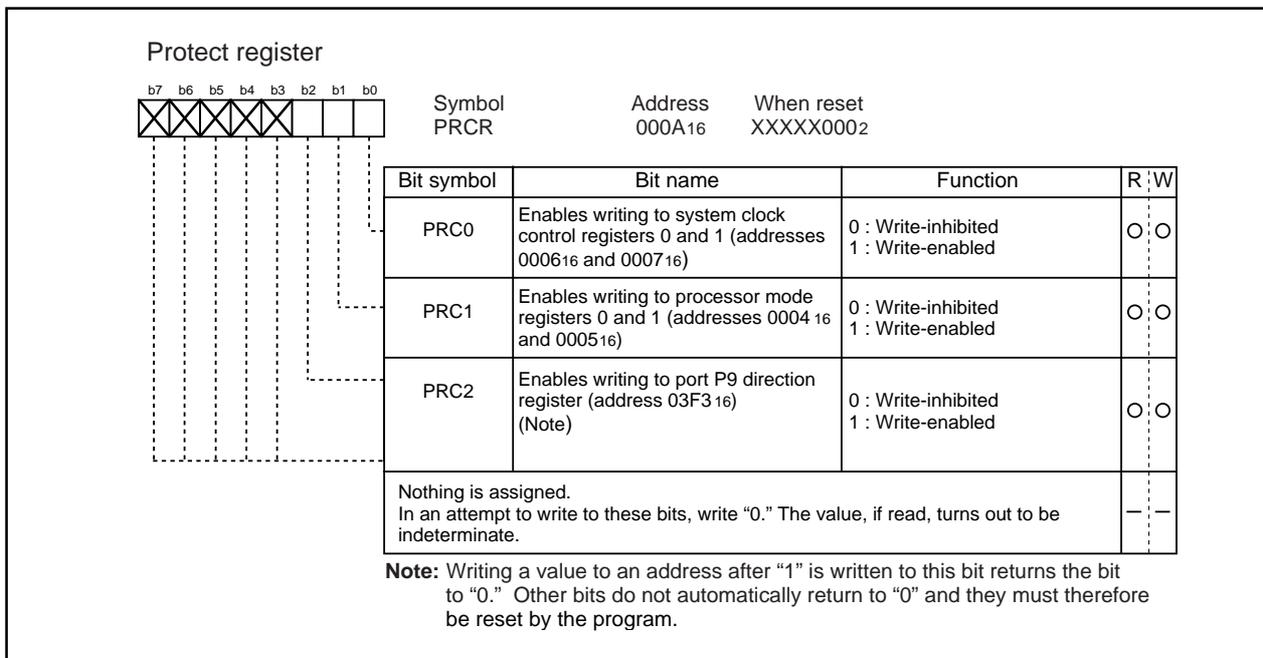

Figure 2.6.1 Protect register

2.7 Interrupts

2.7.1 Type of Interrupts

Figure 2.7.1 lists the types of interrupts.

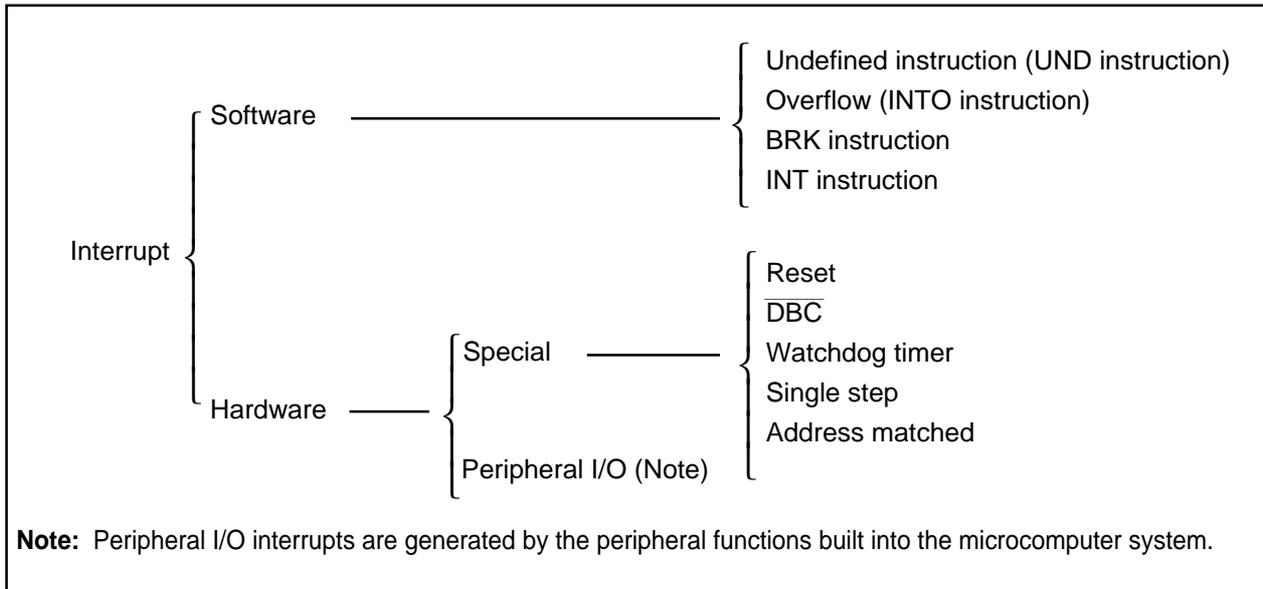

Figure 2.7.1 Classification of interrupts

- Maskable interrupt : An interrupt which can be enabled (disabled) by the interrupt enable flag (I flag) or whose interrupt priority **can be changed** by priority level.
- Non-maskable interrupt : An interrupt which cannot be enabled (disabled) by the interrupt enable flag (I flag) or whose interrupt priority **cannot be changed** by priority level.

2.7.2 Software Interrupts

A software interrupt occurs when executing certain instructions. Software interrupts are non-maskable interrupts.

- **Undefined instruction interrupt**

An undefined instruction interrupt occurs when executing the UND instruction.

- **Overflow interrupt**

An overflow interrupt occurs when executing the INTO instruction with the overflow flag (O flag) set to "1". The following are instructions whose O flag changes by arithmetic:

ABS, ADC, ADCF, ADD, CMP, DIV, DIVU, DIVX, NEG, RMPA, SBB, SHA, SUB

- **BRK interrupt**

A BRK interrupt occurs when executing the BRK instruction.

- **INT interrupt**

An INT interrupt occurs when assigning one of software interrupt numbers 0 through 63 and executing the INT instruction. Software interrupt numbers 0 through 31 are assigned to peripheral I/O interrupts, so executing the INT instruction allows executing the same interrupt routine that a peripheral I/O interrupt does.

The stack pointer (SP) used for the INT interrupt is dependent on which software interrupt number is involved.

So far as software interrupt numbers 0 through 31 are concerned, the microcomputer saves the stack pointer assignment flag (U flag) when it accepts an interrupt request. If change the U flag to "0" and select the interrupt stack pointer (ISP), and then execute an interrupt sequence. When returning from the interrupt routine, the U flag is returned to the state it was before the acceptance of interrupt request. So far as software numbers 32 through 63 are concerned, the stack pointer does not make a shift.

2.7.3 Hardware Interrupts

Hardware interrupts are classified into two types — special interrupts and peripheral I/O interrupts.

(1) Special interrupts

Special interrupts are non-maskable interrupts.

- **Reset**

Reset occurs if an “L” is input to the $\overline{\text{RESET}}$ pin.

- **DBC interrupt**

This interrupt is exclusively for the debugger, do not use it in other circumstances.

- **Watchdog timer interrupt**

Generated by the watchdog timer.

- **Single-step interrupt**

This interrupt is exclusively for the debugger, do not use it in other circumstances. With the debug flag (D flag) set to “1,” a single-step interrupt occurs after one instruction is executed.

- **Address match interrupt**

An address match interrupt occurs immediately before the instruction held in the address indicated by the address match interrupt register is executed with the address match interrupt enable bit set to “1.” If an address other than the first address of the instruction in the address match interrupt register is set, no address match interrupt occurs. For address match interrupt, see 2.11 Address match Interrupt.

(2) Peripheral I/O interrupts

A peripheral I/O interrupt is generated by one of built-in peripheral functions. Built-in peripheral functions are dependent on classes of products, so the interrupt factors too are dependent on classes of products. The interrupt vector table is the same as the one for software interrupt numbers 0 through 31 the INI instruction uses. Peripheral I/O interrupts are maskable interrupts.

- **Bus collision detection interrupt**

This is an interrupt that the serial I/O bus collision detection generates.

- **DMA0 interrupt, DMA1 interrupt**

These are interrupts DMA generates.

- **V_{SYNC} interrupt**

V_{SYNC} interrupt occurs if a V_{SYNC} edge is input.

- **A-D conversion interrupt**

This is an interrupt that the A-D converter generates.

- **UART0 transmission, UART2 transmission interrupts**

These are interrupts that the serial I/O transmission generates.

- **UART0 reception, UART2 reception interrupts**

These are interrupts that the serial I/O reception generates.

- **Multi-master I²C-BUS interface 0 and multi-master I²C-BUS interface 1 interrupts**

This is an interrupt that the serial I/O transmission/reception is completed, or a STOP condition is detected.

- **Timer A0 interrupt through timer A4 interrupt**

These are interrupts that timer A generates

- **Timer B0 interrupt through timer B2 interrupt**

These are interrupts that timer B generates.

M306V5ME-XXXSP
M306V5EESPSINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

• $\overline{\text{INT0}}$ interrupt and $\overline{\text{INT1}}$ interrupt

An $\overline{\text{INT}}$ interrupt occurs if either a rising edge or a falling edge or a both edge is input to the $\overline{\text{INT}}$ pin.

• OSD1 interrupt and OSD2 interrupt

These are interrupts that OSD display is completed.

• Data slicer interrupt

This is an interrupt that data slicer circuit requests.

2.7.4 Interrupts and Interrupt Vector Tables

If an interrupt request is accepted, a program branches to the interrupt routine set in the interrupt vector table. Set the first address of the interrupt routine in each vector table. Figure 2.7.2 shows the format for specifying the address.

Two types of interrupt vector tables are available — fixed vector table in which addresses are fixed and variable vector table in which addresses can be varied by the setting.

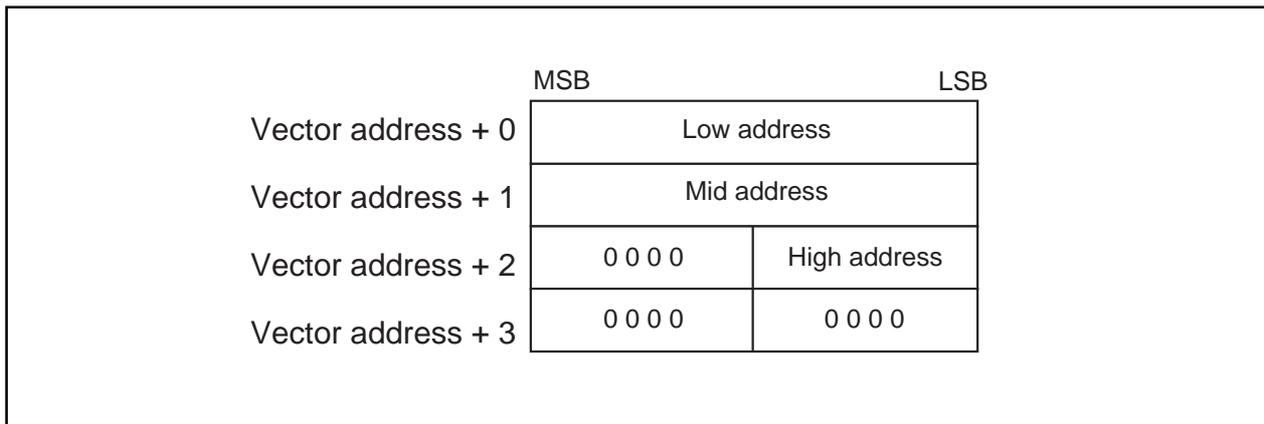

Figure 2.7.2 Format for specifying interrupt vector addresses

(1) Fixed vector tables

The fixed vector table is a table in which addresses are fixed. The vector tables are located in an area extending from FFFDC₁₆ to FFFFF₁₆. One vector table comprises four bytes. Set the first address of interrupt routine in each vector table. Table 2.7.1 shows the interrupts assigned to the fixed vector tables and addresses of vector tables.

Table 2.7.1 Interrupts assigned to the fixed vector tables and addresses of vector tables

| Interrupt source | Vector table addresses Address (L) to address (H) | Remarks |
|-----------------------|--|--|
| Undefined instruction | FFFD ₁₆ to FFFD ₁₆ | Interrupt on UND instruction |
| Overflow | FFFE ₀ ₁₆ to FFFE ₃ ₁₆ | Interrupt on INTO instruction |
| BRK instruction | FFFE ₄ ₁₆ to FFFE ₇ ₁₆ | If the vector is filled with FF ₁₆ , program execution starts from the address shown by the vector in the variable vector table |
| Address match | FFFE ₈ ₁₆ to FFFE _B ₁₆ | There is an address-matching interrupt enable bit |
| Single step (Note) | FFFE _C ₁₆ to FFFE _F ₁₆ | Do not use |
| Watchdog timer | FFFF ₀ ₁₆ to FFFF ₃ ₁₆ | |
| DBC (Note) | FFFF ₄ ₁₆ to FFFF ₇ ₁₆ | Do not use |
| Reserved source | FFFE ₈ ₁₆ to FFFE _B ₁₆ | Do not use |
| Reset | FFFF _C ₁₆ to FFFF _F ₁₆ | |

Note: Interrupts used for debugging purposes only.

| Software interrupt number 31 | +124 to +127 (Note) | Reserved source | |
| Software interrupt number 32 to Software interrupt number 63 | +128 to +131 (Note) to +252 to +255 (Note) | Software interrupt | Cannot be masked I flag |

Note: Address relative to address in interrupt table register (INTB).

2.7.5 Interrupt Control

Descriptions are given here regarding how to enable or disable maskable interrupts and how to set the priority to be accepted. What is described here does not apply to non-maskable interrupts.

Enable or disable a non-maskable interrupt using the interrupt enable flag (I flag), interrupt priority level selection bit, or processor interrupt priority level (IPL). Whether an interrupt request is present or absent is indicated by the interrupt request bit. The interrupt request bit and the interrupt priority level selection bit are located in the interrupt control register of each interrupt. Also, the interrupt enable flag (I flag) and the IPL are located in the flag register (FLG).

Figure 2.7.3 shows the interrupt control registers.

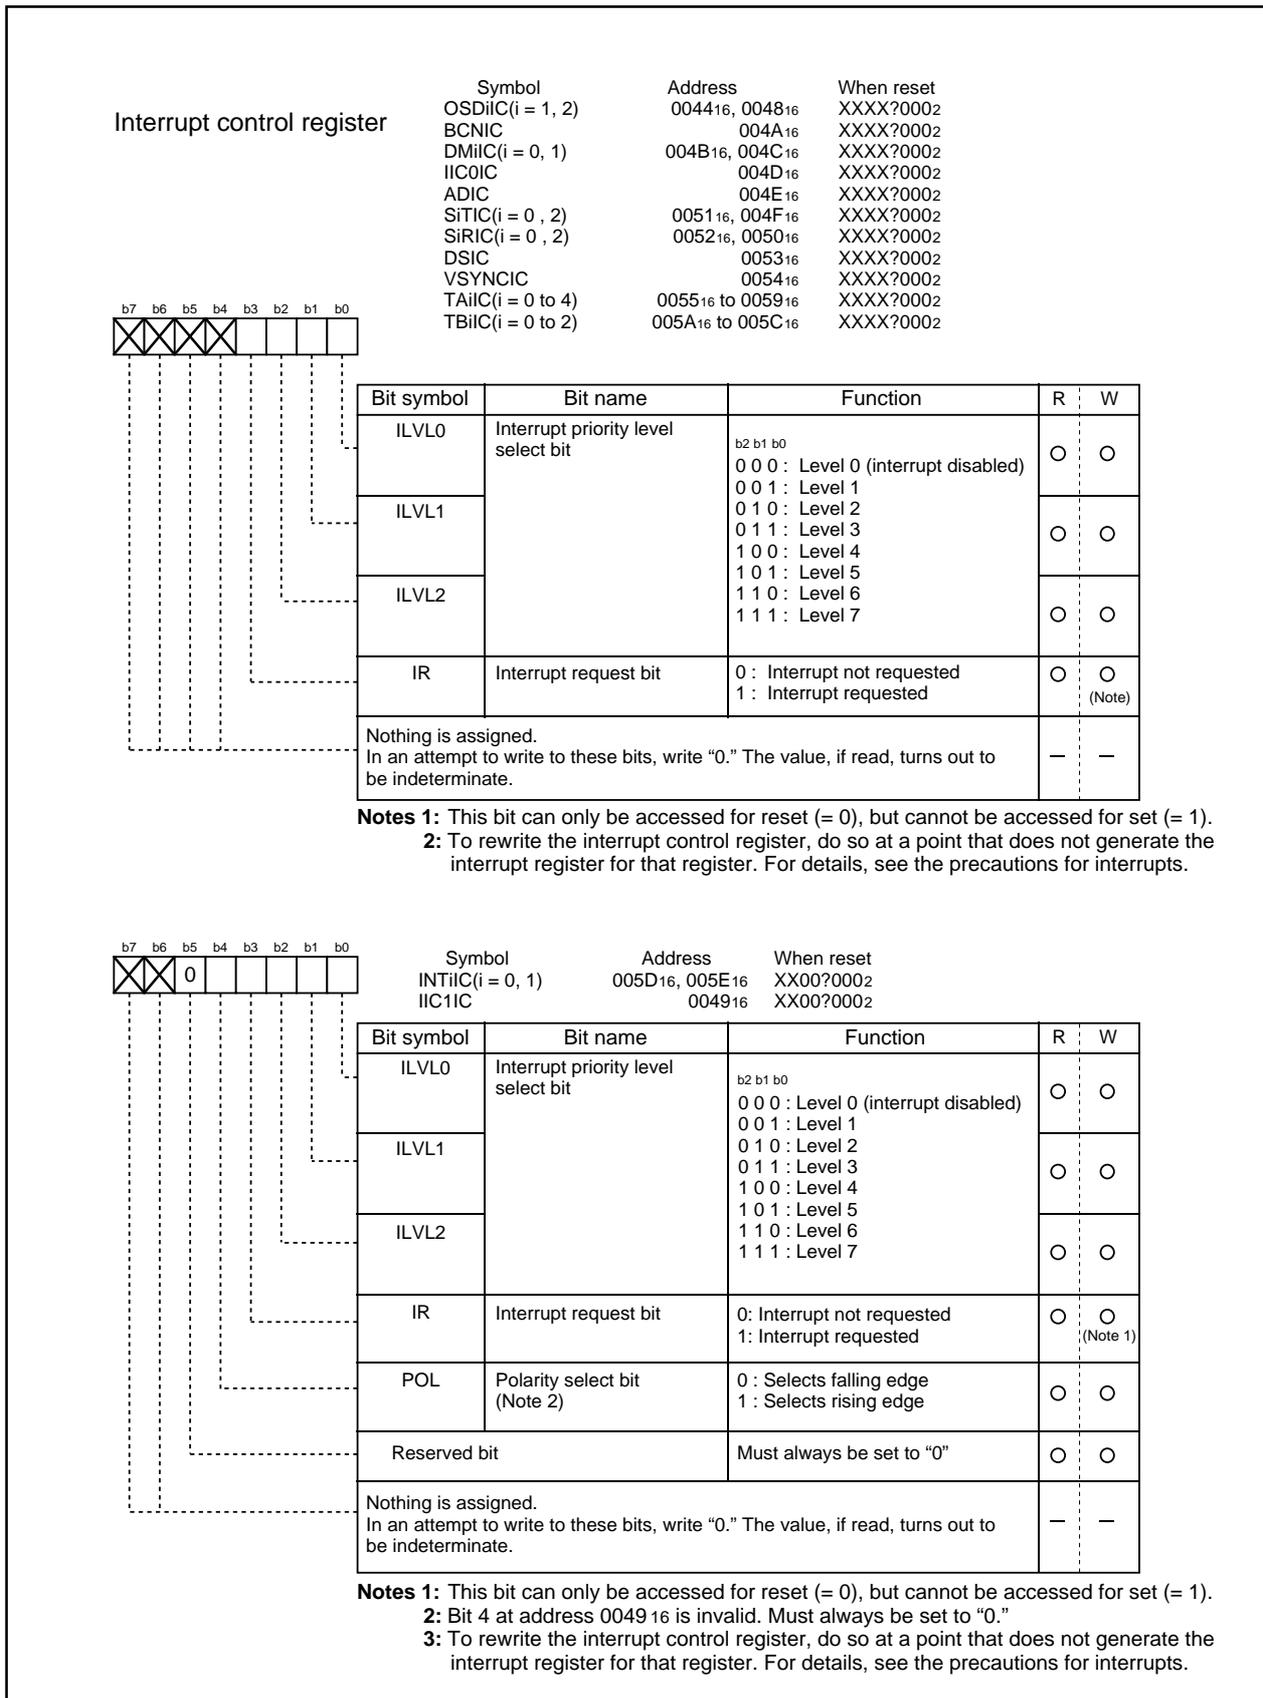

Figure 2.7.3 Interrupt control registers

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.7.6 Interrupt Enable Flag (I flag)

The interrupt enable flag (I flag) controls the enabling and disabling of maskable interrupts. Setting this flag to "1" enables all maskable interrupts; setting it to "0" disables all maskable interrupts. This flag is set to "0" after reset.

2.7.7 Interrupt Request Bit

The interrupt request bit is set to "1" by hardware when an interrupt is requested. After the interrupt is accepted and jumps to the corresponding interrupt vector, the request bit is set to "0" by hardware. The interrupt request bit can also be set to "0" by software. (Do not set this bit to "1").

2.7.8 Interrupt Priority Level Select Bit and Processor Interrupt Priority Level (IPL)

Set the interrupt priority level using the interrupt priority level select bit, which is one of the component bits of the interrupt control register. When an interrupt request occurs, the interrupt priority level is compared with the IPL. The interrupt is enabled only when the priority level of the interrupt is higher than the IPL. Therefore, setting the interrupt priority level to "0" disables the interrupt.

Table 2.7.3 shows the settings of interrupt priority levels and Table 2.7.4 shows the interrupt levels enabled, according to the consist of the IPL.

The following are conditions under which an interrupt is accepted:

- interrupt enable flag (I flag) = 1
- interrupt request bit = 1
- interrupt priority level > IPL

The interrupt enable flag (I flag), the interrupt request bit, the interrupt priority select bit, and the IPL are independent, and they are not affected by one another.

Table 2.7.3 Settings of interrupt priority levels

| Interrupt priority level select bit | Interrupt priority level | Priority order |
|-------------------------------------|------------------------------|--|
| b2 b1 b0 0 0 0 | Level 0 (interrupt disabled) | ———— |
| 0 0 1 | Level 1 | Low  High |
| 0 1 0 | Level 2 | |
| 0 1 1 | Level 3 | |
| 1 0 0 | Level 4 | |
| 1 0 1 | Level 5 | |
| 1 1 0 | Level 6 | |
| 1 1 1 | Level 7 | |

Table 2.7.4 Interrupt levels enabled according to the contents of the IPL

| IPL | Enabled interrupt priority levels |
|---|--|
| IPL ₂ IPL ₁ IPL ₀ 0 0 0 | Interrupt levels 1 and above are enabled |
| 0 0 1 | Interrupt levels 2 and above are enabled |
| 0 1 0 | Interrupt levels 3 and above are enabled |
| 0 1 1 | Interrupt levels 4 and above are enabled |
| 1 0 0 | Interrupt levels 5 and above are enabled |
| 1 0 1 | Interrupt levels 6 and above are enabled |
| 1 1 0 | Interrupt levels 7 and above are enabled |
| 1 1 1 | All maskable interrupts are disabled |

2.7.9 Rewrite Interrupt Control Register

To rewrite the interrupt control register, do so at a point that does not generate the interrupt request for that register. If there is possibility of the interrupt request occur, rewrite the interrupt control register after the interrupt is disabled. The program examples are described as follow:

Example 1:

```
INT_SWITCH1:
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  NOP
  NOP
  FSET  I           ; Enable interrupts.
```

Example 2:

```
INT_SWITCH2:
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  MOV.W MEM, R0    ; Dummy read.
  FSET  I           ; Enable interrupts.
```

Example 3:

```
INT_SWITCH3:
  PUSHC FLG        ; Push Flag register onto stack
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  POPC  FLG        ; Enable interrupts.
```

The reason why two NOP instructions or dummy read are inserted before FSET I in Examples 1 and 2 is to prevent the interrupt enable flag I from being set before the interrupt control register is rewritten due to effects of the instruction queue.

When a instruction to rewrite the interrupt control register is executed but the interrupt is disabled, the interrupt request bit is not set sometimes even if the interrupt request for that register has been generated. This will depend on the instruction. If this creates problems, use the below instructions to change the register.

Instructions : AND, OR, BCLR, BSET

2.7.10 Interrupt Sequence

An interrupt sequence — what are performed over a period from the instant an interrupt is accepted to the instant the interrupt routine is executed — is described here.

If an interrupt occurs during execution of an instruction, the processor determines its priority when the execution of the instruction is completed, and transfers control to the interrupt sequence from the next cycle. If an interrupt occurs during execution of either the SMOVB, SMOVF, SSTR or RMPA instruction, the processor temporarily suspends the instruction being executed, and transfers control to the interrupt sequence.

In the interrupt sequence, the processor carries out the following in sequence given:

- (1) CPU gets the interrupt information (the interrupt number and interrupt request level) by reading address 00000₁₆.
- (2) Saves the content of the flag register (FLG) as it was immediately before the start of interrupt sequence in the temporary register (Note) within the CPU.
- (3) Sets the interrupt enable flag (I flag), the debug flag (D flag), and the stack pointer select flag (U flag) to "0" (the U flag, however does not change if the INT instruction, in software interrupt numbers 32 through 63, is executed)
- (4) Saves the content of the temporary register (Note 1) within the CPU in the stack area.
- (5) Saves the content of the program counter (PC) in the stack area.
- (6) Sets the interrupt priority level of the accepted instruction in the IPL.

After the interrupt sequence is completed, the processor resumes executing instructions from the first address of the interrupt routine.

Note: This register cannot be utilized by the user.

2.7.11 Interrupt Response Time

'Interrupt response time' is the period between the instant an interrupt occurs and the instant the first instruction within the interrupt routine has been executed. This time comprises the period from the occurrence of an interrupt to the completion of the instruction under execution at that moment (a) and the time required for executing the interrupt sequence (b). Figure 2.7.4 shows the interrupt response time.

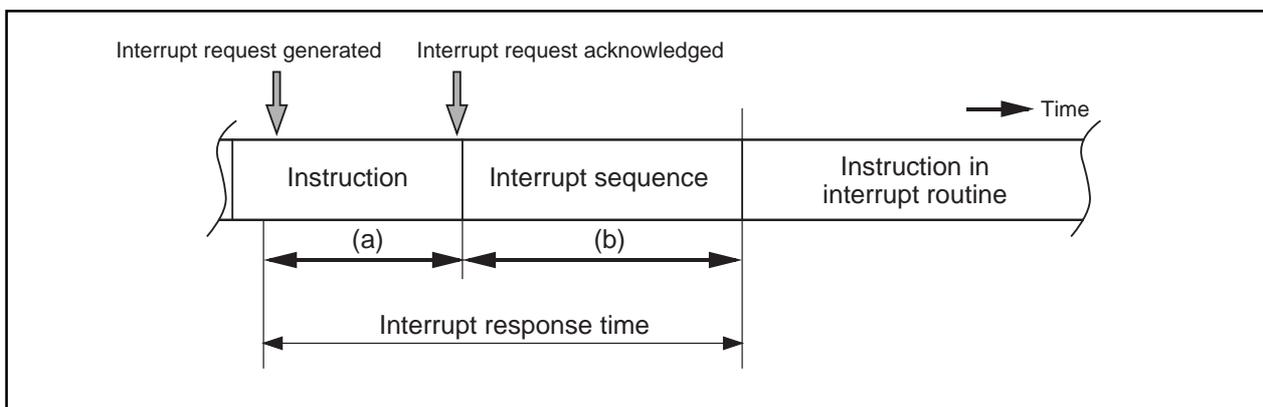

Figure 2.7.4 Interrupt response time

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

Time (a) is dependent on the instruction under execution. Thirty cycles is the maximum required for the DIVX instruction (without wait).

Time (b) is as shown in Table 2.7.5.

Table 2.7.5 Time required for executing the interrupt sequence

| Interrupt vector address | Stack pointer (SP) value | 16-Bit bus, without wait | 8-Bit bus, without wait |
|--------------------------|--------------------------|--------------------------|-------------------------|
| Even | Even | 18 cycles (Note 1) | 20 cycles (Note 1) |
| Even | Odd | 19 cycles (Note 1) | 20 cycles (Note 1) |
| Odd (Note 2) | Even | 19 cycles (Note 1) | 20 cycles (Note 1) |
| Odd (Note 2) | Odd | 20 cycles (Note 1) | 20 cycles (Note 1) |

Notes 1: Add 2 cycles in the case of a DBC interrupt; add 1 cycle in the case either of an address coincidence interrupt or of a single-step interrupt.

2: Locate an interrupt vector address in an even address, if possible.

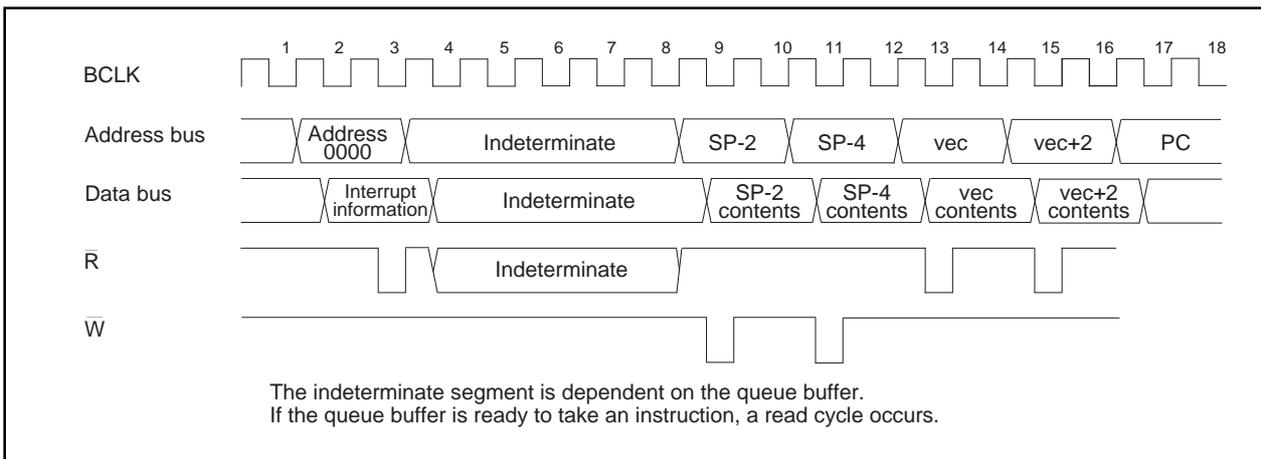

Figure 2.7.5 Time required for executing the interrupt sequence

2.7.12 Variation of IPL when Interrupt Request is Accepted

If an interrupt request is accepted, the interrupt priority level of the accepted interrupt is set in the IPL.

If an interrupt request, that does not have an interrupt priority level, is accepted, one of the values shown in Table 2.7.6 is set in the IPL.

Table 2.7.6 Relationship between interrupts without interrupt priority levels and IPL

| Interrupt sources without priority levels | Value set in the IPL |
|---|----------------------|
| Watchdog timer | 7 |
| Reset | 0 |
| Other | Not changed |

2.7.13 Saving Registers

In the interrupt sequence, only the contents of the flag register (FLG) and that of the program counter (PC) are saved in the stack area.

First, the processor saves the four higher-order bits of the program counter, and 4 upper-order bits and 8 lower-order bits of the FLG register, 16 bits in total, in the stack area, then saves 16 lower-order bits of the program counter. Figure 2.7.6 shows the state of the stack as it was before the acceptance of the interrupt request, and the state the stack after the acceptance of the interrupt request.

Save other necessary registers at the beginning of the interrupt routine using software. Using the PUSHM instruction alone can save all the registers except the stack pointer (SP).

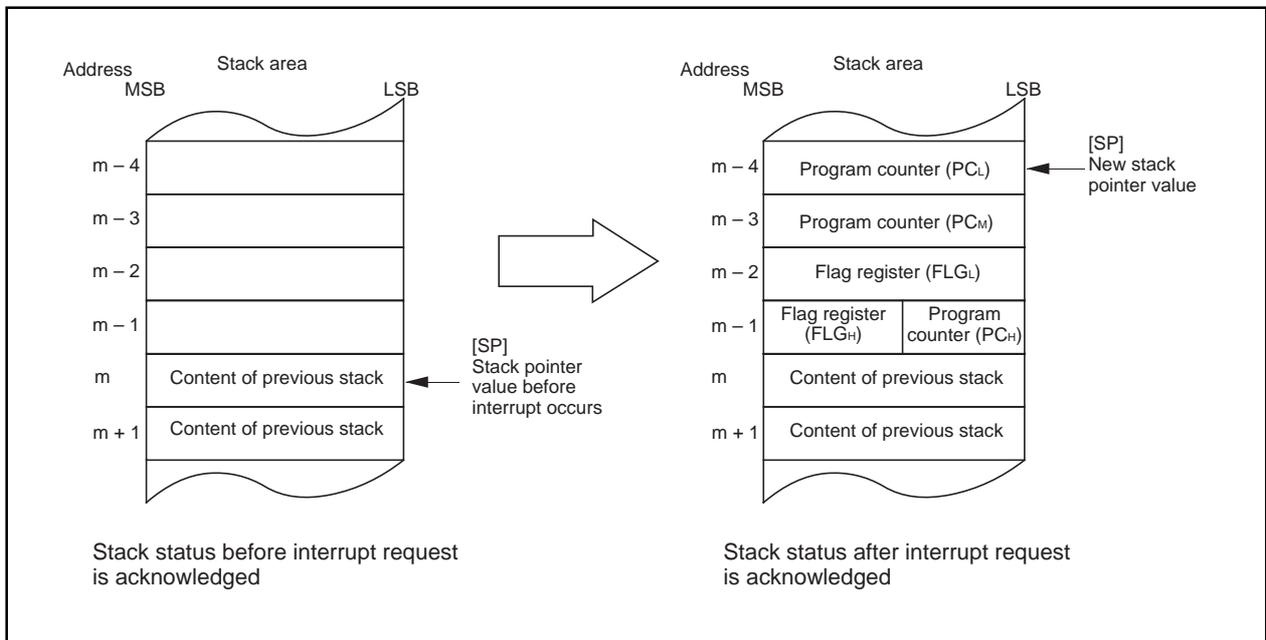

Figure 2.7.6 State of stack before and after acceptance of interrupt request

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

The operation of saving registers carried out in the interrupt sequence is dependent on whether the content of the stack pointer, at the time of acceptance of an interrupt request, is even or odd. If the content of the stack pointer (Note) is even, the content of the flag register (FLG) and the content of the program counter (PC) are saved, 16 bits at a time. If odd, their contents are saved in two steps, 8 bits at a time. Figure 2.7.7 shows the operation of the saving registers.

Note: Stack pointer indicated by U flag.

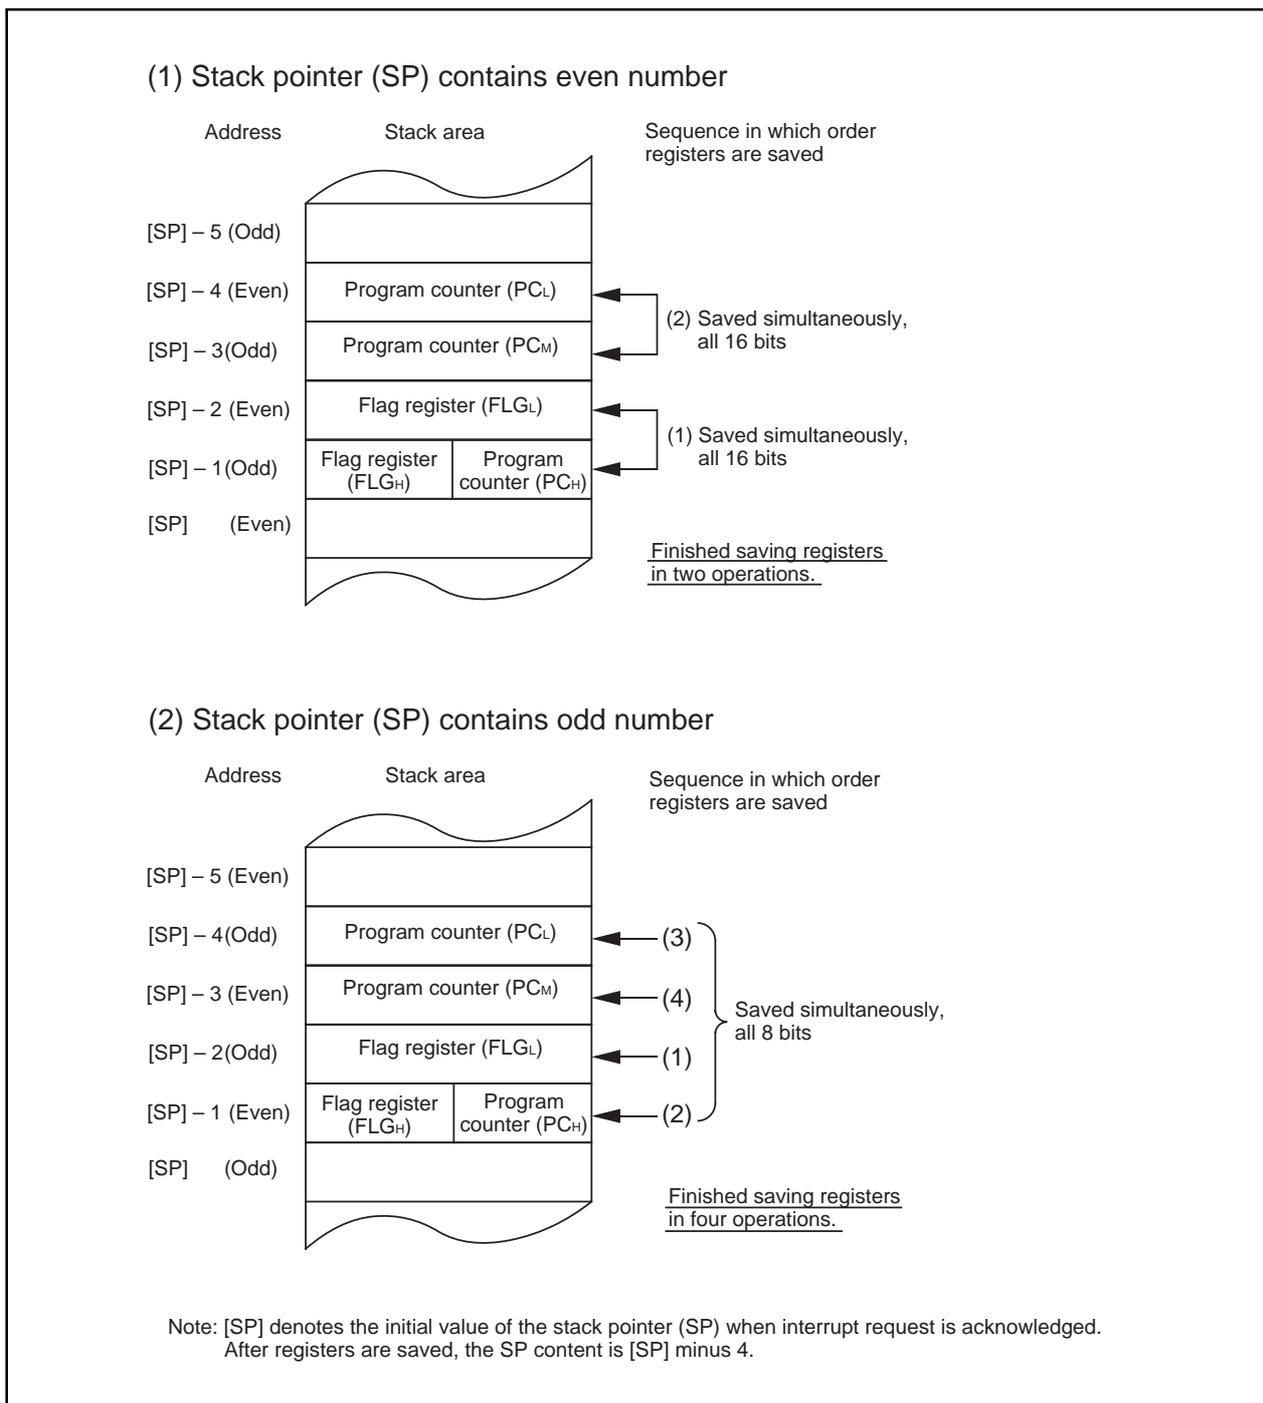

Figure 2.7.7 Operation of saving registers

2.7.14 Returning from an Interrupt Routine

Executing the REIT instruction at the end of an interrupt routine returns the contents of the flag register (FLG) as it was immediately before the start of interrupt sequence and the contents of the program counter (PC), both of which have been saved in the stack area. Then control returns to the program that was being executed before the acceptance of the interrupt request, so that the suspended process resumes.

Return the other registers saved by software within the interrupt routine using the POPM or similar instruction before executing the REIT instruction.

2.7.15 Interrupt Priority

If there are two or more interrupt requests occurring at a point in time within a single sampling (checking whether interrupt requests are made), the interrupt assigned a higher priority is accepted.

Assign an arbitrary priority to maskable interrupts (peripheral I/O interrupts) using the interrupt priority level select bit. If the same interrupt priority level is assigned, however, the interrupt assigned a higher hardware priority is accepted.

Priorities of the special interrupts, such as Reset (dealt with as an interrupt assigned the highest priority), watchdog timer interrupt, etc. are regulated by hardware.

Figure 2.7.8 shows the priorities of hardware interrupts.

Software interrupts are not affected by the interrupt priority. If an instruction is executed, control branches invariably to the interrupt routine.

2.7.16 Interrupt priority level resolution circuit

When two or more interrupts are generated simultaneously, this circuit selects the interrupt with the highest priority level.

Figure 2.7.9 shows the circuit that judges the interrupt priority level.

Reset > \overline{DBC} > Watchdog timer > Peripheral I/O > Single step > Address match

Figure 2.7.8 Hardware interrupts priorities

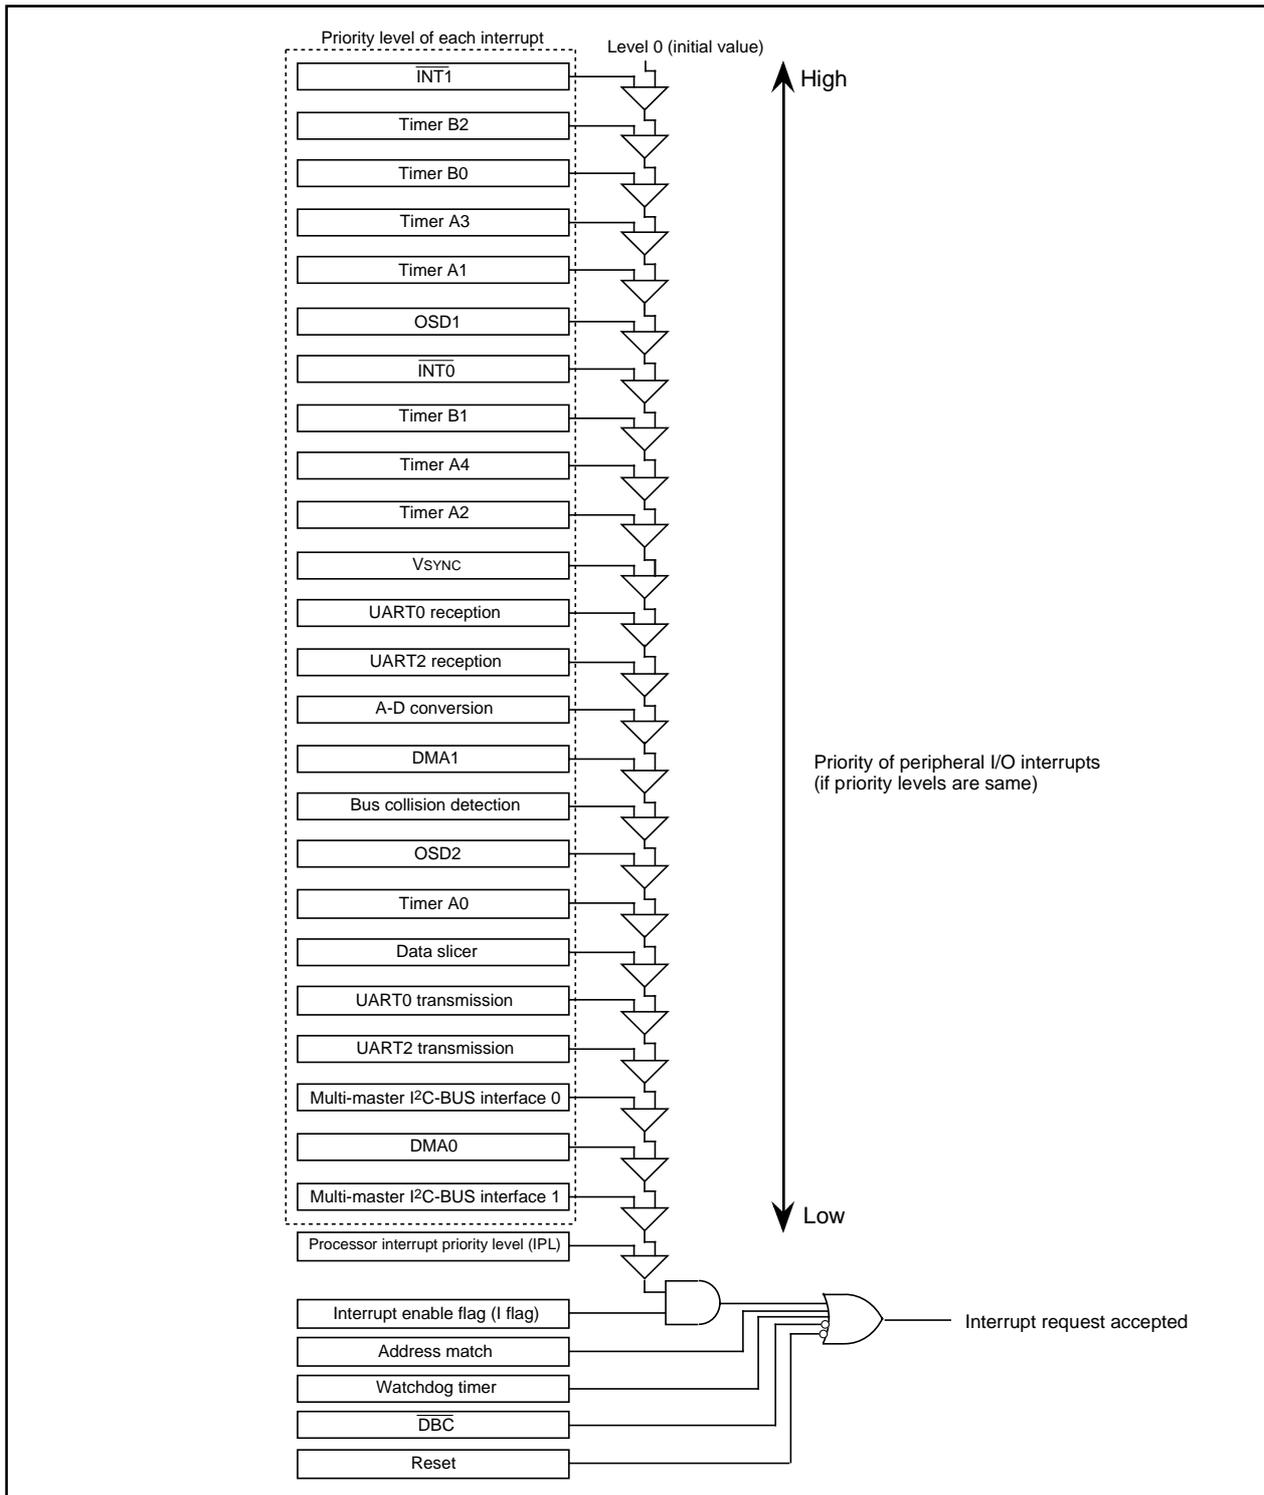

Figure 2.7.9 Maskable interrupts priorities (peripheral I/O interrupts)

2.7.17 INT Interrupt

$\overline{INT0}$ and $\overline{INT1}$ are triggered by the edges of external inputs. The edge polarity is selected using the polarity select bit.

As for external interrupt input, an interrupt can be generated both at the rising edge and at the falling edge by setting "1" in the INTi interrupt polarity switching bit of the interrupt request cause select register (035F₁₆). To select both edges, set the polarity switching bit of the corresponding interrupt control register to 'falling edge' ("0").

Figure 2.7.10 shows the Interrupt control reserved register, Figure 2.7.11 shows the Interrupt request cause select register.

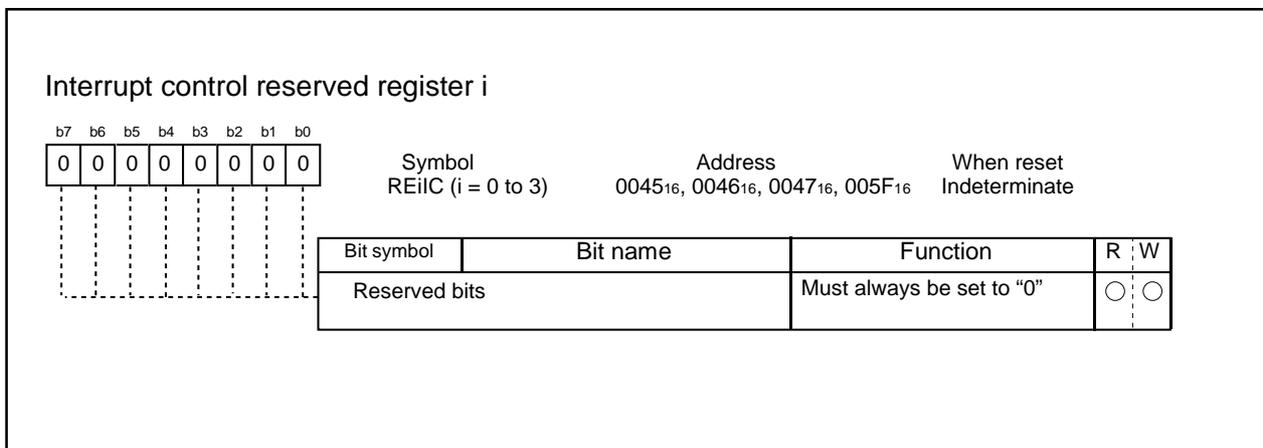

Figure 2.7.10 Interrupt control reserved register i (i = 0 to 3)

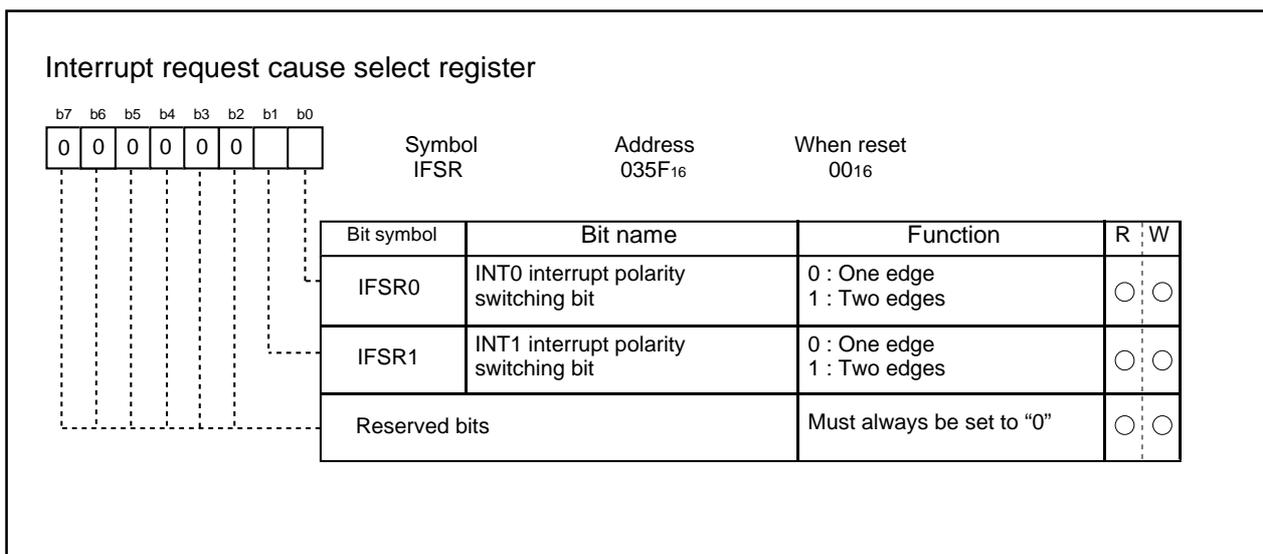

Figure 2.7.11 Interrupt request cause select register

2.7.18 Address Match Interrupt

An address match interrupt is generated when the address match interrupt address register contents match the program counter value. Two address match interrupts can be set, each of which can be enabled and disabled by an address match interrupt enable bit. Address match interrupts are not affected by the interrupt enable flag (I flag) and processor interrupt priority level (IPL). The value of the program counter (PC) for an address match interrupt varies depending on the instruction being executed. Figures 2.7.12 and 2.7.13 show the address match interrupt-related registers.

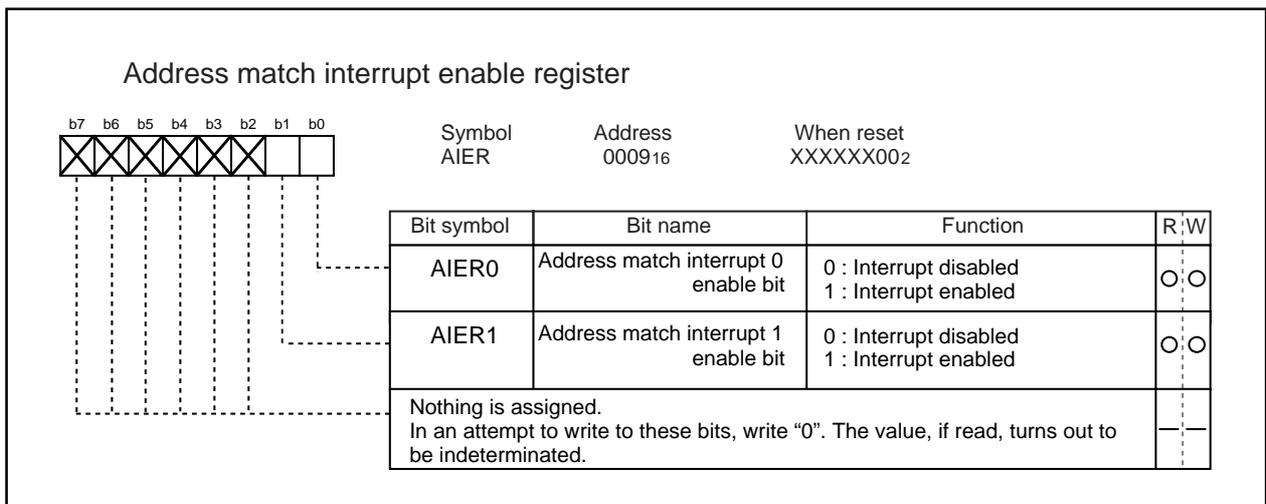

Figure 2.7.12 Address match interrupt enable register

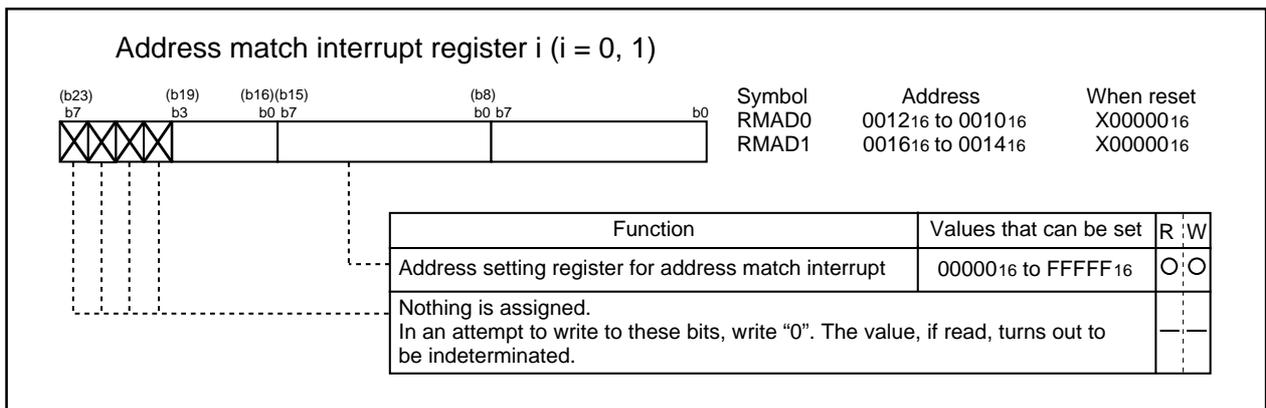

Figure 2.7.13 Address match interrupt register i (i = 0, 1)

2.7.19 Precautions for Interrupts

(1) Reading address 00000₁₆

- When maskable interrupt is occurred, CPU read the interrupt information (the interrupt number and interrupt request level) in the interrupt sequence.

The interrupt request bit of the certain interrupt written in address 00000₁₆ will then be set to "0".

Reading address 00000₁₆ by software sets enabled highest priority interrupt source request bit to "0".

Though the interrupt is generated, the interrupt routine may not be executed.

Do not read address 00000₁₆ by software.

(2) Setting the stack pointer

- The value of the stack pointer immediately after reset is initialized to 0000₁₆. Accepting an interrupt before setting a value in the stack pointer may become a factor of runaway. Be sure to set a value in the stack pointer before accepting an interrupt.

(3) External interrupt

- Either an "L" level or an "H" level of at least 250 ns width is necessary for the signal input to pins $\overline{\text{INT}}_0$ and $\overline{\text{INT}}_1$ regardless of the CPU operation clock.
- When the polarity of the $\overline{\text{INT}}_0$ and $\overline{\text{INT}}_1$ pins is changed, the interrupt request bit is sometimes set to "1". After changing the polarity, set the interrupt request bit to "0". Figure 2.7.14 shows the procedure for changing the $\overline{\text{INT}}$ interrupt generate factor.

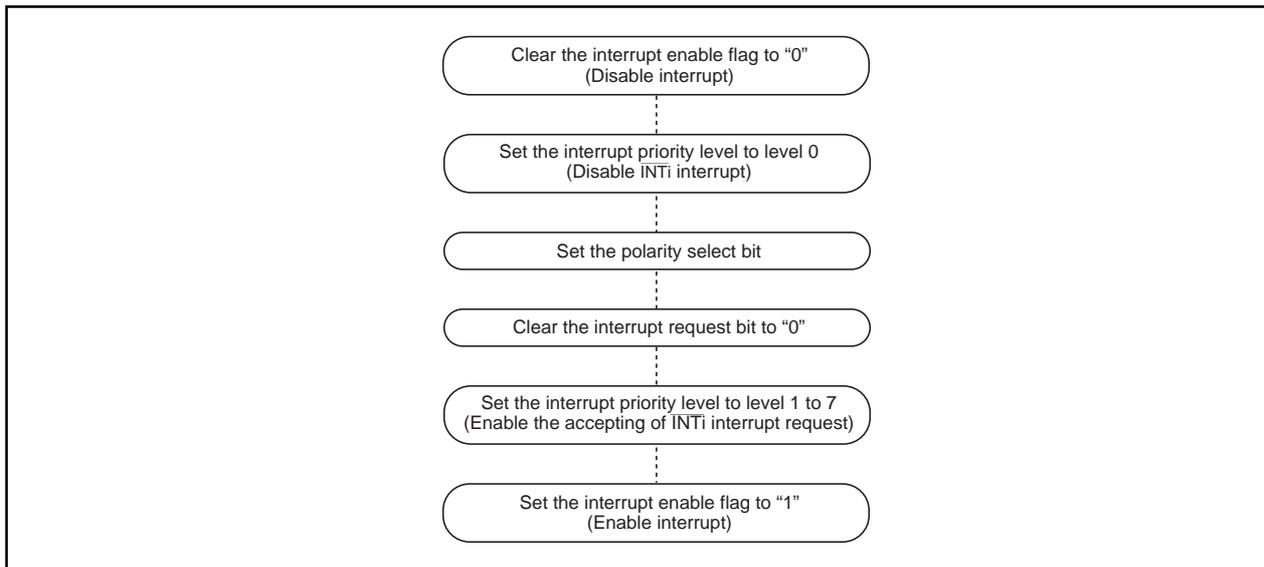

Figure 2.7.14 Switching condition of INT interrupt request

(4) Rewrite interrupt control register

- To rewrite the interrupt control register, do so at a point that does not generate the interrupt request for that register. If there is possibility of the interrupt request occur, rewrite the interrupt control register after the interrupt is disabled. The program examples are described as follow:

Example 1:

```

INT_SWITCH1:
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  NOP
  NOP
  FSET  I           ; Enable interrupts.

```

Example 2:

```

INT_SWITCH2:
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  MOV.W MEM, R0    ; Dummy read.
  FSET  I           ; Enable interrupts.

```

Example 3:

```

INT_SWITCH3:
  PUSHC FLG        ; Push Flag register onto stack
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  POPC  FLG        ; Enable interrupts.

```

The reason why two NOP instructions or dummy read are inserted before FSET I in Examples 1 and 2 is to prevent the interrupt enable flag I from being set before the interrupt control register is rewritten due to effects of the instruction queue.

- When a instruction to rewrite the interrupt control register is executed but the interrupt is disabled, the interrupt request bit is not set sometimes even if the interrupt request for that register has been generated. This will depend on the instruction. If this creates problems, use the below instructions to change the register.

Instructions : AND, OR, BCLR, BSET

2.8 Watchdog Timer

The watchdog timer has the function of detecting when the program is out of control. The watchdog timer is a 15-bit counter which down-counts the clock derived by dividing the BCLK using the prescaler. A watchdog timer interrupt is generated when an underflow occurs in the watchdog timer. Bit 7 of the watchdog timer control register (address 000F₁₆) selects the prescaler division ratio (by 16 or by 128). Thus the watchdog timer's period can be calculated as given below. The watchdog timer's period is, however, subject to an error due to the pre-scaler.

$$\text{Watchdog timer period} = \frac{\text{pre-scaler dividing ratio (16 or 128)} \times \text{watchdog timer count (32768)}}{\text{BCLK}}$$

For example suppose that BCLK runs at 10 MHz and that 16 has been chosen for the dividing ratio of the pre-scaler, then the watchdog timer's period becomes approximately 52.4 ms.

The watchdog timer is initialized by writing to the watchdog timer start register (address 000E₁₆) and when a watchdog timer interrupt request is generated. The prescaler is initialized only when the microcomputer is reset. After a reset is cancelled, the watchdog timer and prescaler are both stopped. The count is started by writing to the watchdog timer start register (address 000E₁₆).

Figure 2.8.1 shows the block diagram of the watchdog timer. Figure 2.8.2 shows the watchdog timer control register and Figure 2.8.3 shows the watchdog timer start register.

2.9 DMAC

This microcomputer has two DMAC (direct memory access controller) channels that allow data to be sent to memory without using the CPU. DMAC shares the same data bus with the CPU. The DMAC is given a higher right of using the bus than the CPU, which leads to working the cycle stealing method. On this account, the operation from the occurrence of DMA transfer request signal to the completion of 1-word (16-bit) or 1-byte (8-bit) data transfer can be performed at high speed. Figure 2.9.1 shows the block diagram of the DMAC. Table 2.9.1 shows the DMAC specifications. Figures 2.9.2 to 2.9.7 show the registers used by the DMAC.

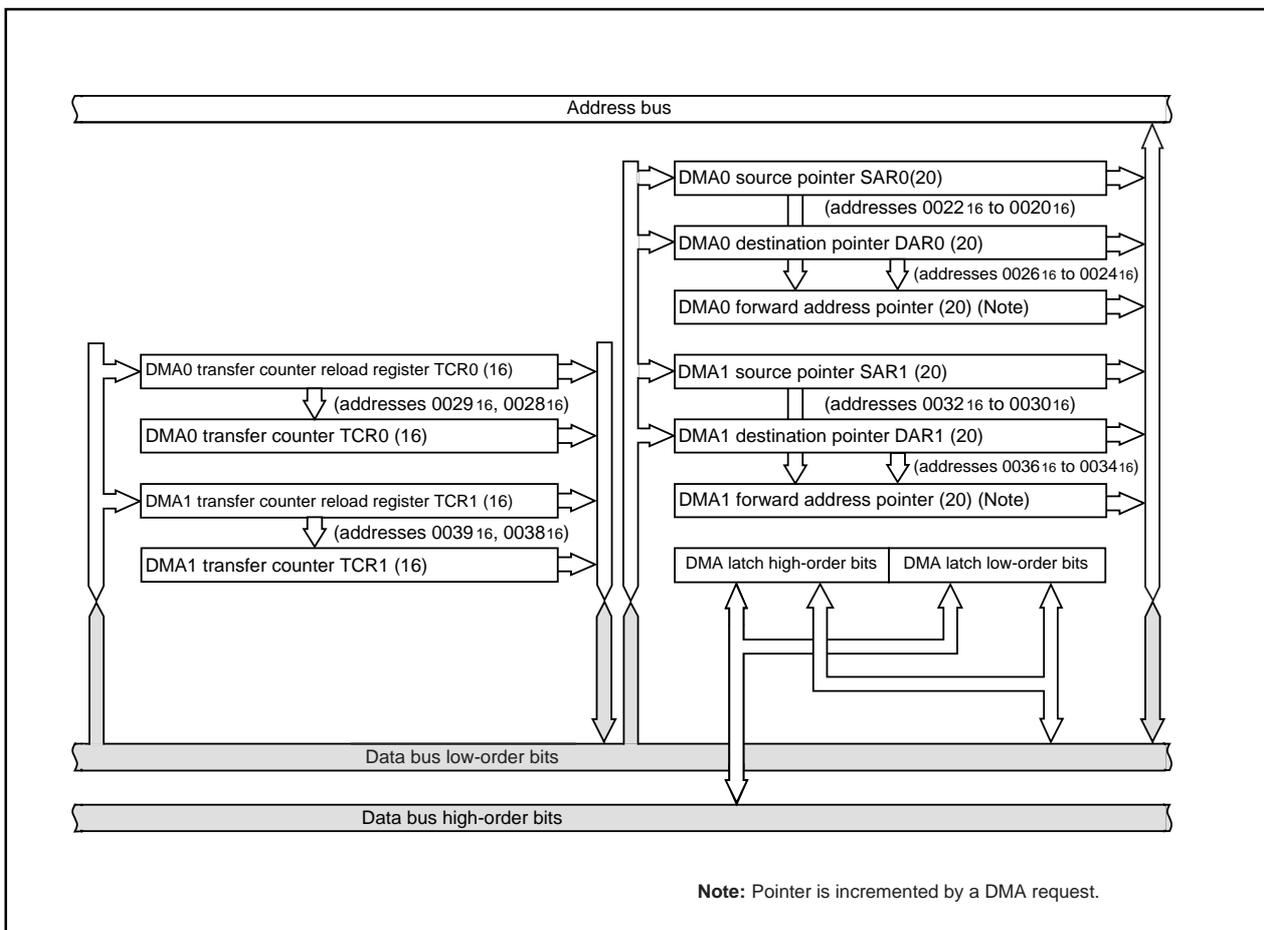

Figure 2.9.1 Block diagram of DMAC

Either a write signal to the software DMA request bit or an interrupt request signal is used as a DMA transfer request signal. But the DMA transfer is affected neither by the interrupt enable flag (I flag) nor by the interrupt priority level. The DMA transfer doesn't affect any interrupts either.

If the DMAC is active (the DMA enable bit is set to 1), data transfer starts every time a DMA transfer request signal occurs. If the cycle of the occurrences of DMA transfer request signals is higher than the DMA transfer cycle, there can be instances in which the number of transfer requests doesn't agree with the number of transfers. For details, see the description of the DMA request bit.

2.9.1 Transfer Cycle

The transfer cycle consists of the bus cycle in which data is read from memory or from the SFR area (source read) and the bus cycle in which the data is written to memory or to the SFR area (destination write). The number of read and write bus cycles depends on the source and destination addresses. Also, the bus cycle itself is longer when software waits are inserted.

(1) Effect of source and destination addresses

When 16-bit data is transferred on a 16-bit data bus, and the source and destination both start at odd addresses, there are one more source read cycle and destination write cycle than when the source and destination both start at even addresses.

(2) Effect of software wait

When the SFR area or a memory area with a software wait is accessed, the number of cycles is increased for the wait by 1 bus cycle. The length of the cycle is determined by BCLK.

Figure 2.9.8 shows the example of the transfer cycles for a source read. For convenience, the destination write cycle is shown as one cycle and the source read cycles for the different conditions are shown. In reality, the destination write cycle is subject to the same conditions as the source read cycle, with the transfer cycle changing accordingly. When calculating the transfer cycle, remember to apply the respective conditions to both the destination write cycle and the source read cycle.

and ON-SCREEN DISPLAY CONTROLLER

2.9.2 DMAC Transfer Cycles

Any combination of even or odd transfer read and write addresses is possible. Table 2.9.2 shows the number of DMAC transfer cycles.

The number of DMAC transfer cycles can be calculated as follows:

$$\text{No. of transfer cycles per transfer unit} = \text{No. of read cycles} \times j + \text{No. of write cycles} \times k$$

Table 2.9.2 No. of DMAC transfer cycles

| Transfer unit | Bus width | Access address | Single-chip mode | |
|----------------------------------|-----------|----------------|--------------------|---------------------|
| | | | No. of read cycles | No. of write cycles |
| 8-bit transfers (DMBIT= "1") | 16-bit | Even | 1 | 1 |
| | | Odd | 1 | 1 |
| 16-bit transfers (DMBIT= "0") | 16-bit | Even | 1 | 1 |
| | | Odd | 2 | 2 |

Coefficient j, k

| Internal memory | | |
|------------------|------------------|-------------------|
| Internal ROM/RAM | Internal ROM/RAM | SFR area /OSD RAM |
| No wait | With wait | No wait |
| 1 | 2 | 2 |

2.9.3 DMA Enable Bit

Setting the DMA enable bit to 1 makes the DMAC active. The DMAC carries out the following operations at the time data transfer starts immediately after DMAC is turned active.

- (1) Reloads the value of one of the source pointer and the destination pointer - the one specified for the forward direction - to the forward direction address pointer.
- (2) Reloads the value of the transfer counter reload register to the transfer counter.

Thus overwriting 1 to the DMA enable bit with the DMAC being active carries out the operations given above, so the DMAC operates again from the initial state at the instant 1 is overwritten to the DMA enable bit.

2.9.4 DMA Request Bit

The DMAC can generate a DMA transfer request signal triggered by a factor chosen in advance out of DMA request factors for each channel.

DMA request factors include the following.

* Factors effected by using the interrupt request signals from the built-in peripheral functions and software DMA factors (internal factors) effected by a program.

* External factors effected by utilizing the input from external interrupt signals.

For the selection of DMA request factors, see the descriptions of the DMA_i factor selection register.

The DMA request bit turns to 1 if the DMA transfer request signal occurs regardless of the DMAC's state (regardless of whether the DMA enable bit is set 1 or to 0). It turns to 0 immediately before data transfer starts.

In addition, it can be set to 0 by use of a program, but cannot be set to 1.

There can be instances in which a change in DMA request factor selection bit causes the DMA request bit to turn to 1. So be sure to set the DMA request bit to 0 after the DMA request factor selection bit is changed.

The DMA request bit turns to 1 if a DMA transfer request signal occurs, and turns to 0 immediately before data transfer starts. If the DMAC is active, data transfer starts immediately, so the value of the DMA request bit, if read by use of a program, turns out to be 0 in most cases. To examine whether the DMAC is active, read the DMA enable bit.

Here follows the timing of changes in the DMA request bit.

(1) Internal factors

Except the DMA request factors triggered by software, the timing for the DMA request bit to turn to 1 due to an internal factor is the same as the timing for the interrupt request bit of the interrupt control register to turn to 1 due to several factors.

Turning the DMA request bit to 1 due to an internal factor is timed to be effected immediately before the transfer starts.

(2) External factors

An external factor is a factor caused to occur by the leading edge of input from the $\overline{\text{INT}}_i$ pin (i depends on which DMAC channel is used).

Selecting the $\overline{\text{INT}}_i$ pins as external factors using the DMA request factor selection bit causes input from these pins to become the DMA transfer request signals.

The timing for the DMA request bit to turn to 1 when an external factor is selected synchronizes with the signal's edge applicable to the function specified by the DMA request factor selection bit (synchronizes with the trailing edge of the input signal to each $\overline{\text{INTi}}$ pin, for example).

With an external factor selected, the DMA request bit is timed to turn to 0 immediately before data transfer starts similarly to the state in which an internal factor is selected.

(3) The priorities of channels and DMA transfer timing

If a DMA transfer request signal falls on a single sampling cycle (a sampling cycle means one period from the leading edge to the trailing edge of BCLK), the DMA request bits of applicable channels concurrently turn to 1. If the channels are active at that moment, DMA0 is given a high priority to start data transfer. When DMA0 finishes data transfer, it gives the bus right to the CPU. When the CPU finishes single bus access, then DMA1 starts data transfer and gives the bus right to the CPU. Figure 2.9.9 illustrates these operations.

An example in which DMA transfer is carried out in minimum cycles at the time when DMA transfer request signals due to external factors concurrently occur.

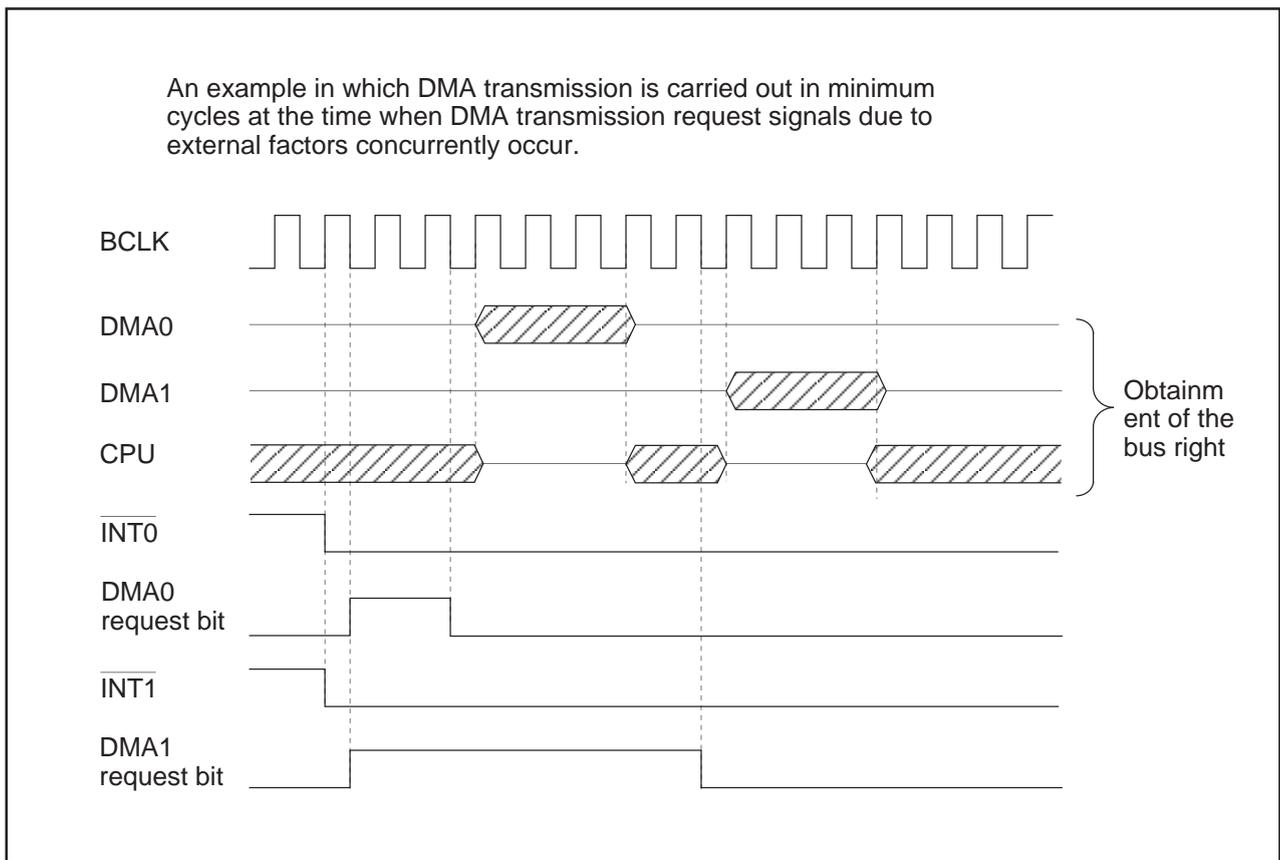

Figure 2.9.9 An example of DMA transfer effected by external factors

2.10 Timer

There are eight 16-bit timers. These timers can be classified by function into timers A (five) and timers B (three). All these timers function independently. Figures 2.10.1 and 2.10.2 show the block diagram of timers.

2.10.1 Timer A

Figure 2.10.3 shows the block diagram of timer A. Figures 2.10.4 to 2.10.10 show the timer A-related registers.

Except the pulse output function, timers A0 through A4 all have the same function. Use the timer Ai mode register (i = 0 to 4) bits 0 and 1 to choose the desired mode.

Timer A has the four operation modes listed as follows:

- Timer mode: The timer counts an internal count source.
- Event counter mode: The timer counts a timer over flow.
- One-shot timer mode: The timer stops counting when the count reaches "0000₁₆".
- Pulse width modulation (PWM) mode: The timer outputs pulses of a given width.

(4) Pulse width modulation (PWM) mode

In this mode, the timer outputs pulses of a given width in succession. (See Table 2.10.4.) In this mode, the counter functions as either a 16-bit pulse width modulator or an 8-bit pulse width modulator. Figure 2.10.14 shows the timer Ai mode register in pulse width modulation mode. Figure 2.10.15 shows the example of how an 8-bit pulse width modulator operates.

2.10.2 Timer B

Figure 2.10.17 shows the block diagram of timer B. Figures 2.10.17 and 2.10.20 show the timer B-related registers.

Use the timer Bi mode register (i = 0 to 2) bits 0 and 1 to choose the desired mode.

Timer B has three operation modes listed as follows:

- Timer mode: The timer counts an internal count source.
- Event counter mode: The timer counts pulses from an external source or a timer overflow.
- Pulse period/pulse width measuring mode: The timer measures an external signal's pulse period or pulse width.

(4) TB0IN noise filter

The input signal of pin TB0IN has the noise filter. The ON/OFF of noise filter and selection of filter clock are set by bits 2 to 4 of the peripheral mode register.

Note: When using the noise filter, set bit 7 of the peripheral mode register according to the main clock frequency.

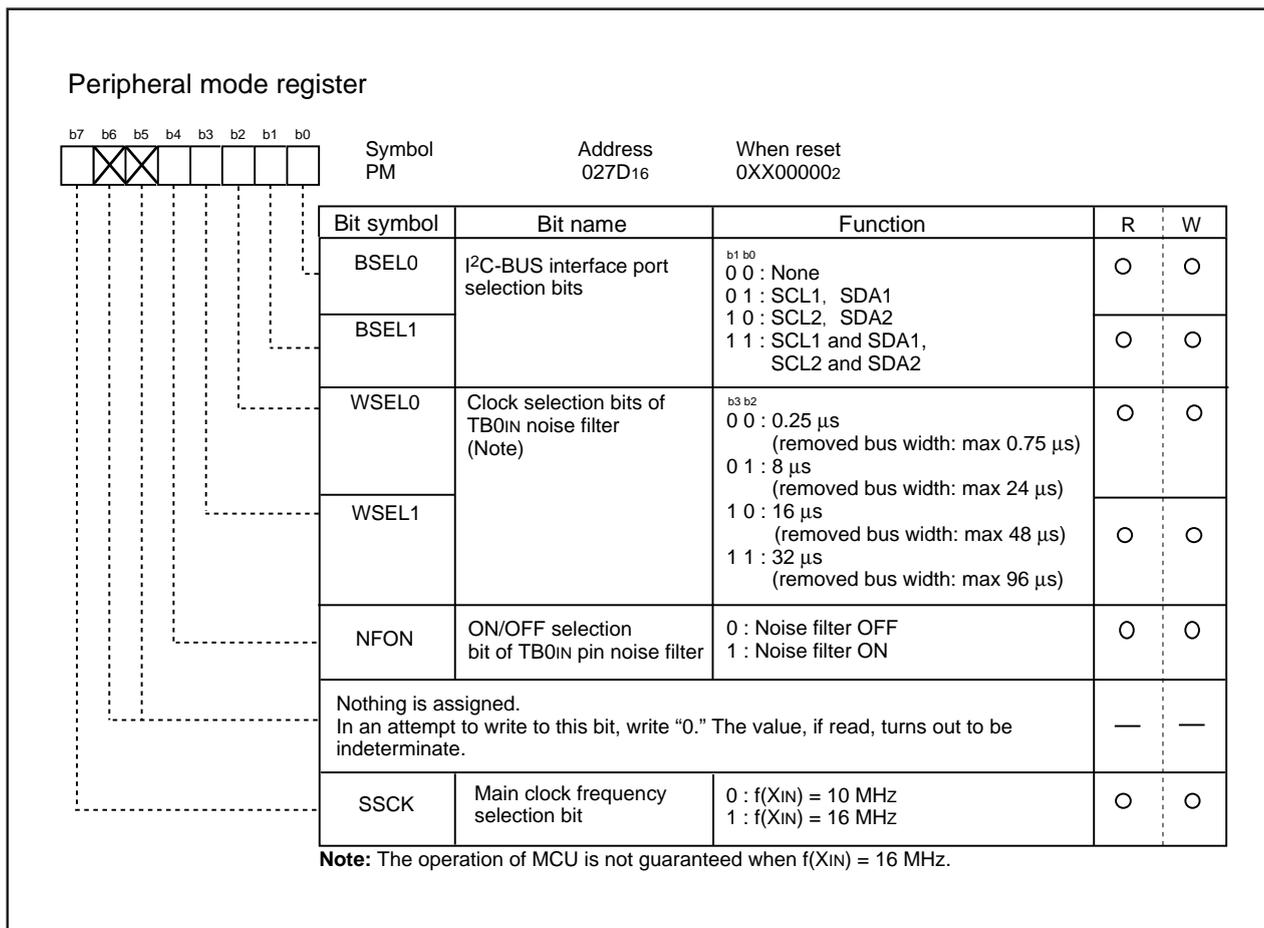

Figure 2.10.28 Peripheral mode register

2.11 Serial I/O

Serial I/O is configured as 4 unites: UART0, UART2, multi-master I²C-BUS interface 0, and multi-master I²C-BUS interface 1.

2.11.1 UART0 and UART2

UART0 and UART2 each have an exclusive timer to generate a transfer clock, so they operate independently of each other.

Figure 2.11.1 shows the block diagram of UART0 and UART2. Figures 2.11.2 and 2.11.3 show the block diagram of the transmit/receive unit.

UART_i (i = 0 and 2) has two operation modes: a clock synchronous serial I/O mode and a clock asynchronous serial I/O mode (UART mode). The contents of the serial I/O mode select bits (bits 0 to 2 at addresses 03A0₁₆ and 0378₁₆) determine whether UART_i is used as a clock synchronous serial I/O or as a UART. Although a few functions are different, UART0 and UART2 have almost the same functions.

UART0 and UART2 are almost equal in their functions with minor exceptions. UART2, in particular, is compliant with the SIM interface. It also has the bus collision detection function that generates an interrupt request if the TxD pin and the RxD pin are different in level.

Table 2.11.1 shows the comparison of functions of UART0 and UART2, and Figures 2.11.4 to 2.11.14 show the registers related to UART_i.

Table 2.11.1 Comparison of functions of UART0 and UART2

| Function | UART0 | UART2 |
|--|-------------------|-----------------------------|
| CLK polarity selection | Possible (Note 1) | Possible (Note 1) |
| LSB first / MSB first selection | Possible (Note 1) | Possible (Note 2) |
| Continuous receive mode selection | Possible (Note 1) | Possible (Note 1) |
| Transfer clock output from multiple pins selection | Impossible | Impossible |
| Serial data logic switch | Impossible | Possible (Note 4) |
| Sleep mode selection | Possible (Note 3) | Impossible |
| TxD, RxD I/O polarity switch | Impossible | Possible |
| TxD, RxD port output format | CMOS output | N-channel open-drain output |
| Parity error signal output | Impossible | Possible (Note 4) |
| Bus collision detection | Impossible | Possible |

Notes 1: Only when clock synchronous serial I/O mode.

2: Only when clock synchronous serial I/O mode and 8-bit UART mode.

3: Only when UART mode.

4: Using for SIM interface.

Table 2.11.4 lists the functions of the input/output pins during clock synchronous serial I/O mode. Note that for a period from when the UARTi operation mode is selected to when transfer starts, the TxDi pin outputs a "H". (If the N-channel open-drain is selected, this pin is in floating state.)

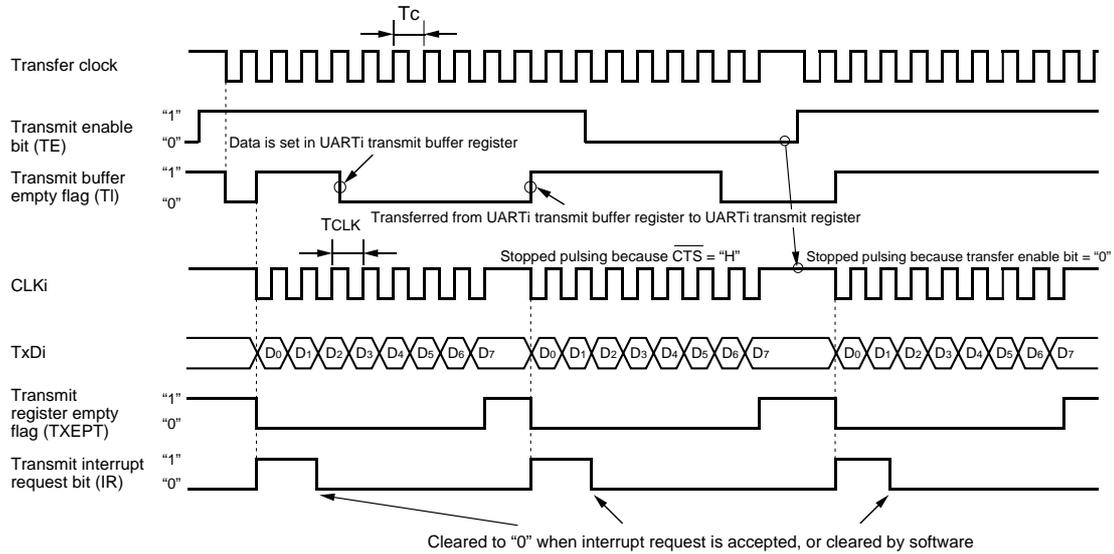

Table 2.11.4 Input/output pin functions in clock synchronous serial I/O mode

| Pin name | Function | Method of selection |
|--------------------|-----------------------|---|
| TxDi (P63, P70) | Serial data output | (Outputs dummy data when performing reception only) |
| RxDi (P62, P71) | Serial data input | Port P62 and P71 direction register (bits 2 at address 03EE ₁₆ , bit 1 at address 03EF ₁₆) = "0" (Can be used as an input port when performing transmission only) |
| CLKi (P55, P72) | Transfer clock output | Internal/external clock select bit (bit 3 at address 03A0 ₁₆ , 0378 ₁₆) = "0" Port P55 and P72 direction register (bit 5 at address 03EB ₁₆ , bit 2 at address 03EF ₁₆) = "0" |
| | Transfer clock input | Internal/external clock select bit (bit 3 at address 03A0 ₁₆ , 0378 ₁₆) = "1" Port P55 and P72 direction register (bit 5 at address 03EB ₁₆ , bit 2 at address 03EF ₁₆) = "0" |

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

• Example of transmit timing (when internal clock is selected)

• Example of receive timing (when external clock is selected)

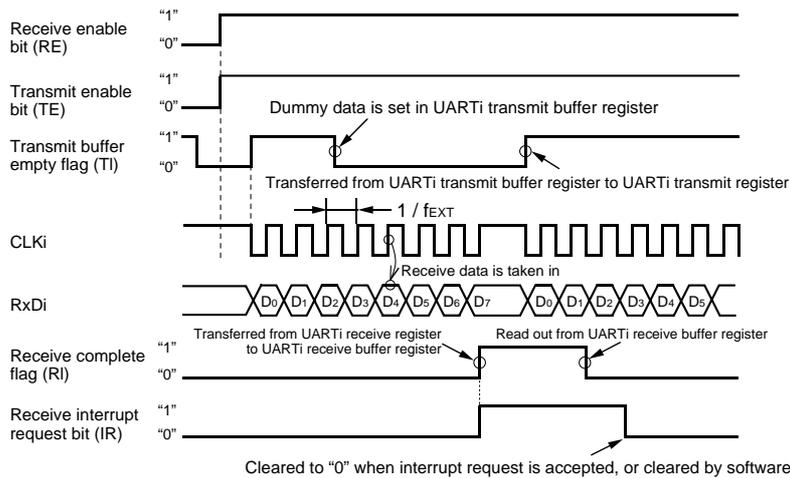

Figure 2.11.17 Typical transmit/receive timings in clock synchronous serial I/O mode

(1) Polarity select function

As shown in Figure 2.11.18, the CLK polarity select bit (bit 6 at addresses 03A4₁₆, 037C₁₆) allows selection of the polarity of the transfer clock.

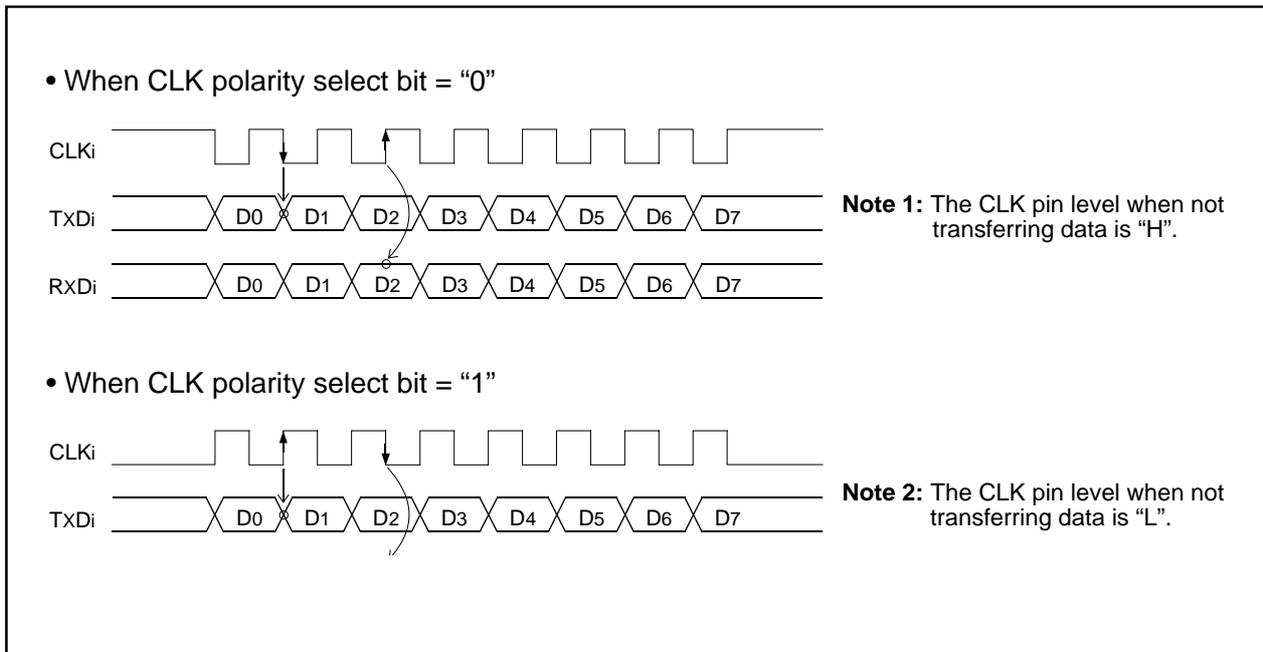

Figure 2.11.18 Polarity of transfer clock

(2) LSB first/MSB first select function

As shown in Figure 2.11.19, when the transfer format select bit (bit 7 at addresses 03A4₁₆, 037C₁₆) = "0", the transfer format is "LSB first"; when the bit = "1", the transfer format is "MSB first".

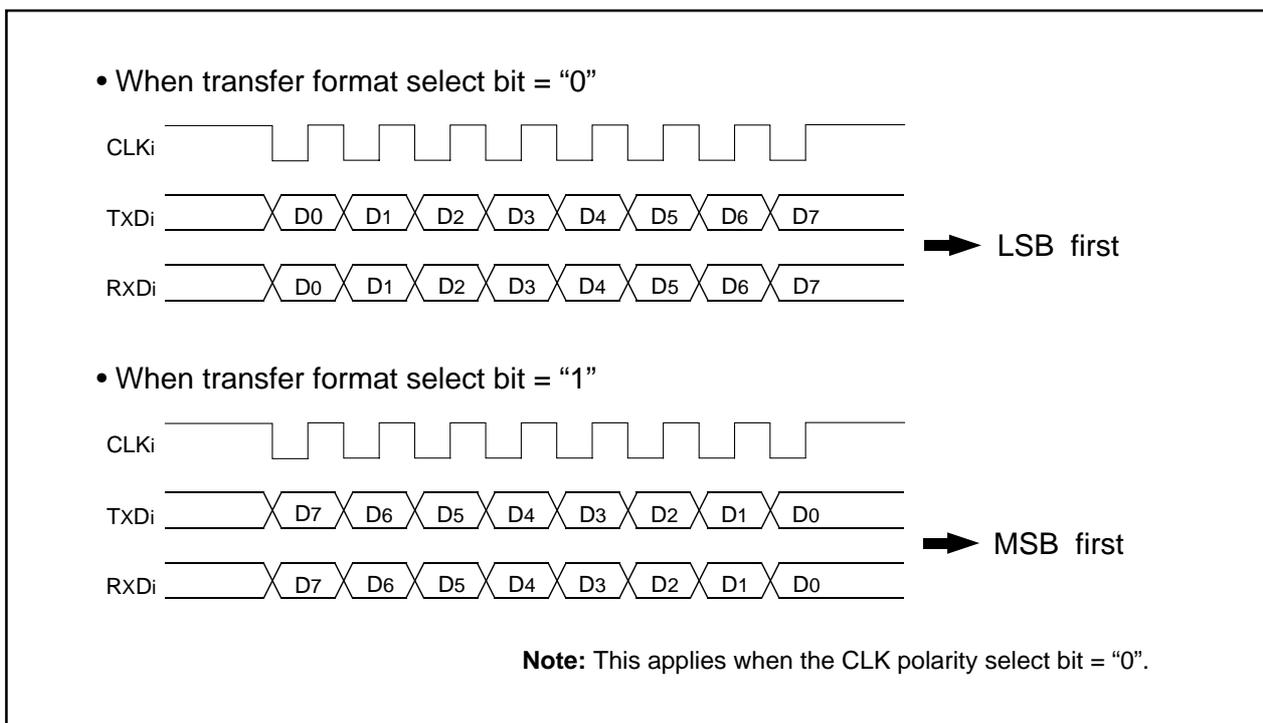

Figure 2.11.19 Transfer format

(3) Continuous receive mode

If the continuous receive mode enable bit (bits 2 at address 03B0₁₆, bit 5 at address 037D₁₆) is set to "1", the unit is placed in continuous receive mode. In this mode, when the receive buffer register is read out, the unit simultaneously goes to a receive enable state without having to set dummy data to the transmit buffer register back again.

(4) Serial data logic switch function (UART2)

When the data logic select bit (bit6 at address 037D₁₆) = "1", and writing to transmit buffer register or reading from receive buffer register, data is reversed. Figure 2.11.20 shows the example of serial data logic switch timing.

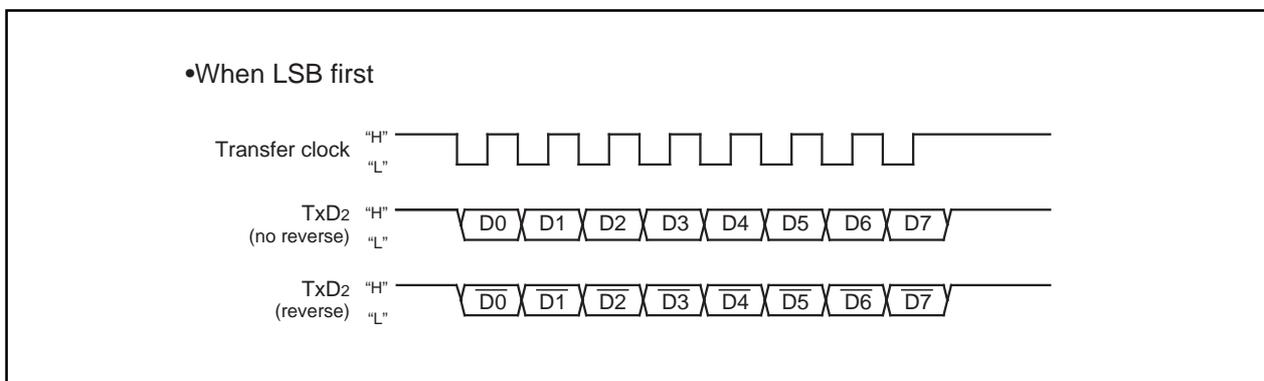

Figure 2.11.20 Serial data logic switch timing

2.11.3 Clock Asynchronous Serial I/O (UART) Mode

The UART mode allows transmitting and receiving data after setting the desired transfer rate and transfer data format. Tables 2.11.5 and 2.11.6 list the specifications of the UART mode. Figure 2.11.21 and 2.11.22 show the UARTi transmit/receive mode register in UART mode.

Table 2.11.5 Specifications of UART Mode (1)

| Item | Specification |
|-------------------------------------|--|

Table 2.11.7 lists the functions of the input/output pins during UART mode. Note that for a period from when the UARTi operation mode is selected to when transfer starts, the TxDi pin outputs a "H". (If the N-channel open-drain is selected, this pin is in floating state.)

Table 2.11.7 Input/output pin functions in UART mode

| Pin name | Function | Method of selection |
|--------------------|-------------------------|---|
| TxDi (P63, P70) | Serial data output | |
| RxDi (P62, P71) | Serial data input | Port P62 and P71 direction register (bit 2 at address 03EE16, bit 1 at address 03EF16) = "0" (Can be used as an input port when performing transmission only) |
| CLKi (P55, P72) | Programmable input port | Internal/external clock select bit (bit 3 at address 03A016, 037816) = "0" Port P55 and P72 direction register (bit 5 at address 03EB16, bit 2 at address 03EF16) = "0" |

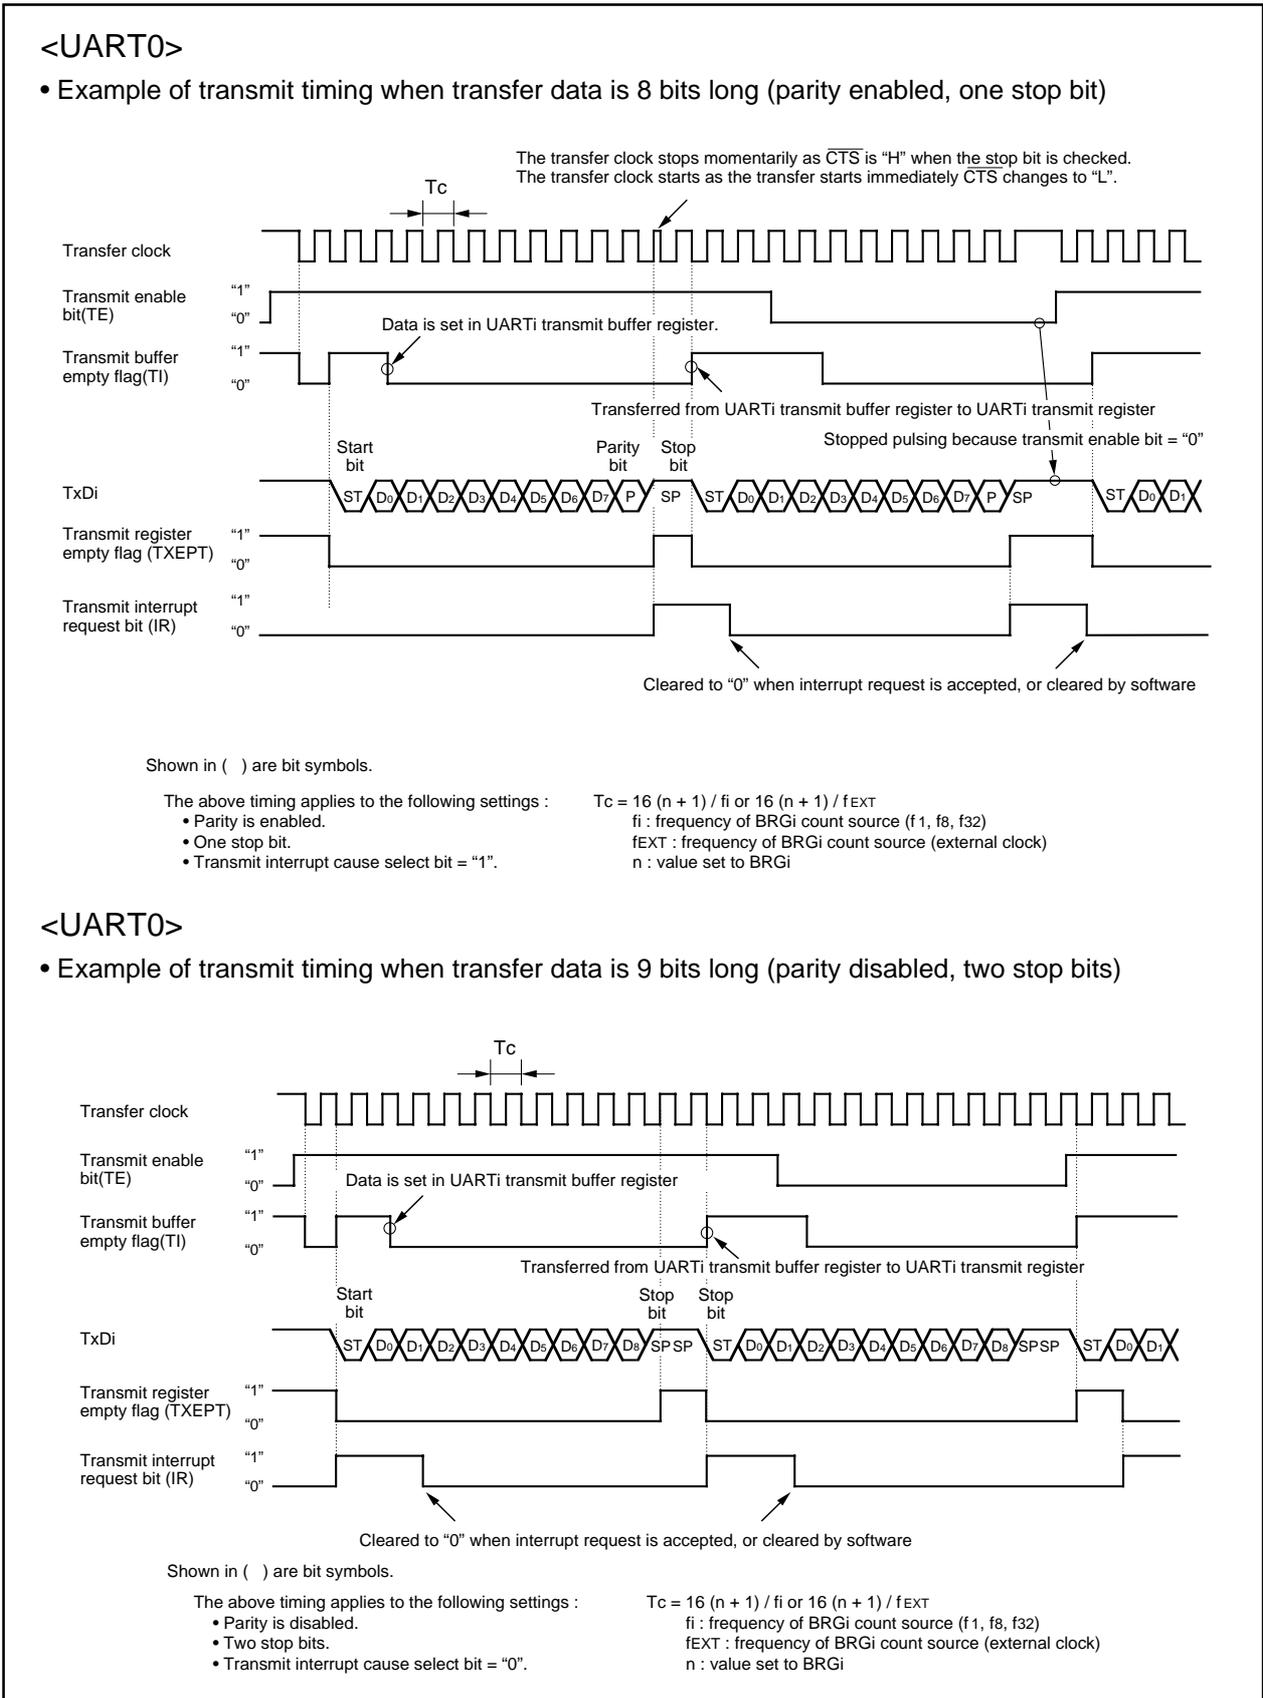

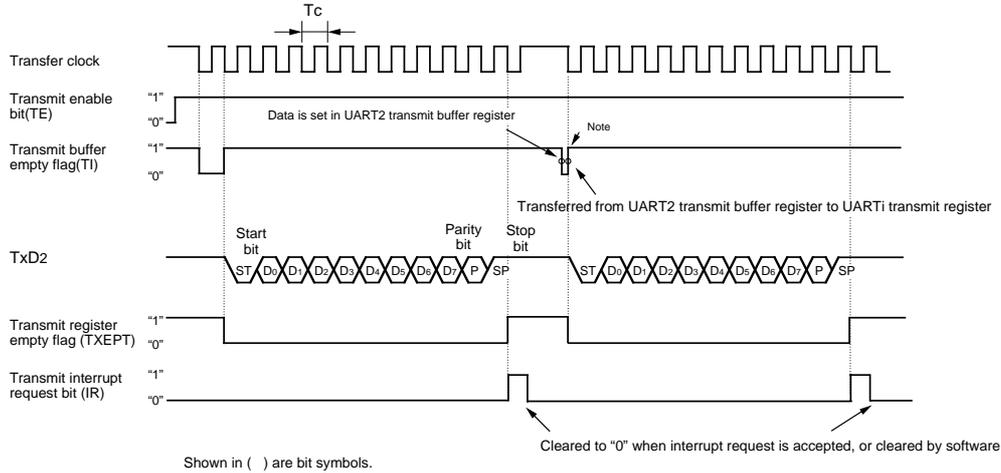

Figure 2.11.23 Typical transmit/receive timings in UART mode

<UART2>

- Example of transmit timing when transfer data is 8 bits long (parity enabled, one stop bit)

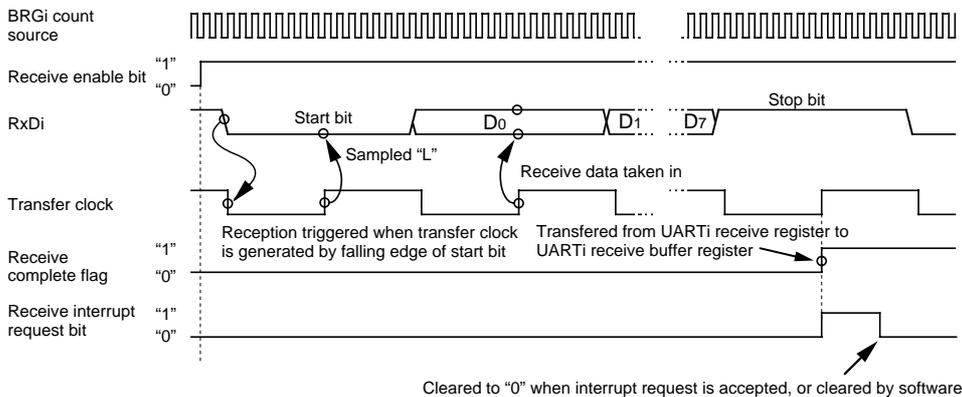

Shown in () are bit symbols.

The above timing applies to the following settings : $T_c = 16(n + 1) / f_i$
 • Parity is enabled. f_i : frequency of BRG2 count source (f_1, f_8, f_{32})
 • One stop bit. n : value set to BRG2
 • Transmit interrupt cause select bit = "1".

Note: The transmit is started with overflow timing of BRG after having written in a value at the transmit buffer in the above timing.

<UART2, UART0>

- Example of receive timing when transfer data is 8 bits long (parity disabled, one stop bit)

The above timing applies to the following settings :
 • Parity is disabled.
 • One stop bit.

Figure 2.11.23 Typical transmit/receive timings in UART mode

(1) Sleep mode (UART0)

This mode is used to transfer data between specific microcomputers among multiple microcomputers connected using UART0. The sleep mode is selected when the sleep select bit (bit 7 at address 03A0₁₆) is set to "1" during reception. In this mode, the unit performs receive operation when the MSB of the received data = "1" and does not perform receive operation when the MSB = "0".

(2) Function for switching serial data logic (UART2)

When the data logic select bit (bit 6 of address 037D₁₆) is assigned 1, data is inverted in writing to the transmission buffer register or reading the reception buffer register. Figure 2.11.24 shows the example of timing for switching serial data logic.

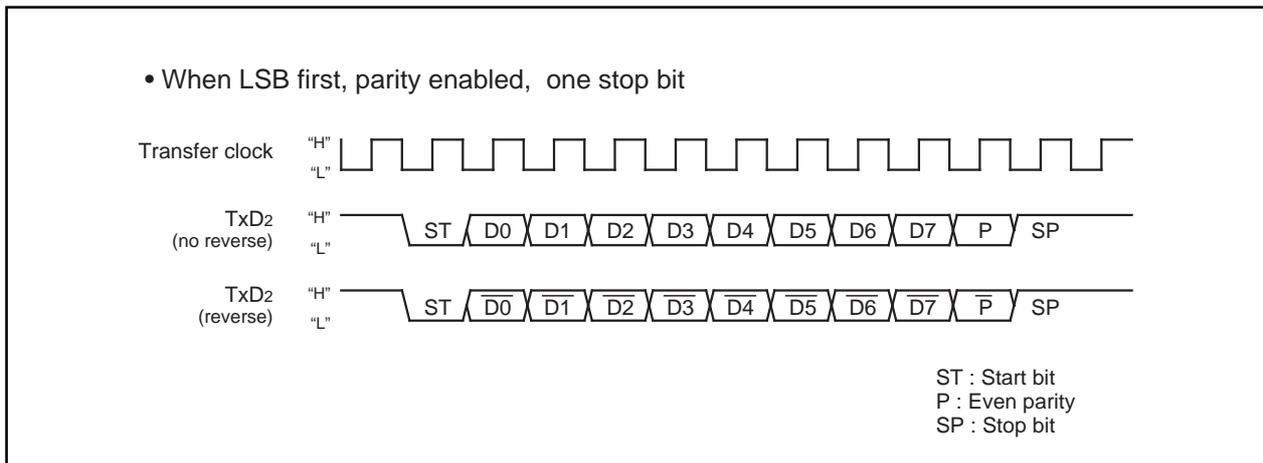

Figure 2.11.24 Timing for switching serial data logic

(3) TxD, RxD I/O polarity reverse function (UART2)

This function is to reverse TxD pin output and RxD pin input. The level of any data to be input or output (including the start bit, stop bit(s), and parity bit) is reversed. Set this function to "0" (not to reverse) for usual use.

(4) Bus collision detection function and other functions (UART2)

This function is to sample the output level of the TxD pin and the input level of the RxD pin at the rising edge of the transfer clock; if their values are different, then an interrupt request occurs. Figure 2.11.26 shows the example of detection timing of a buss collision (in UART mode).

And also, bit 5 of the special UART2 mode register is used as the selection bit for auto clear function select bit of enable bit. Setting this bit to "1" automatically resets the transmit enable bit to "0" when "1" is set in the bus collision detection interrupt request bit (nonconformity) (refer to Figure 2.11.25).

Bit 6 of the special UART2 mode register is used as the transmit start condition select bit. Setting this bit to "1" starts the TxD transmission in synchronization with the falling edge of the RxD terminal (refer to Figure 2.11.26).

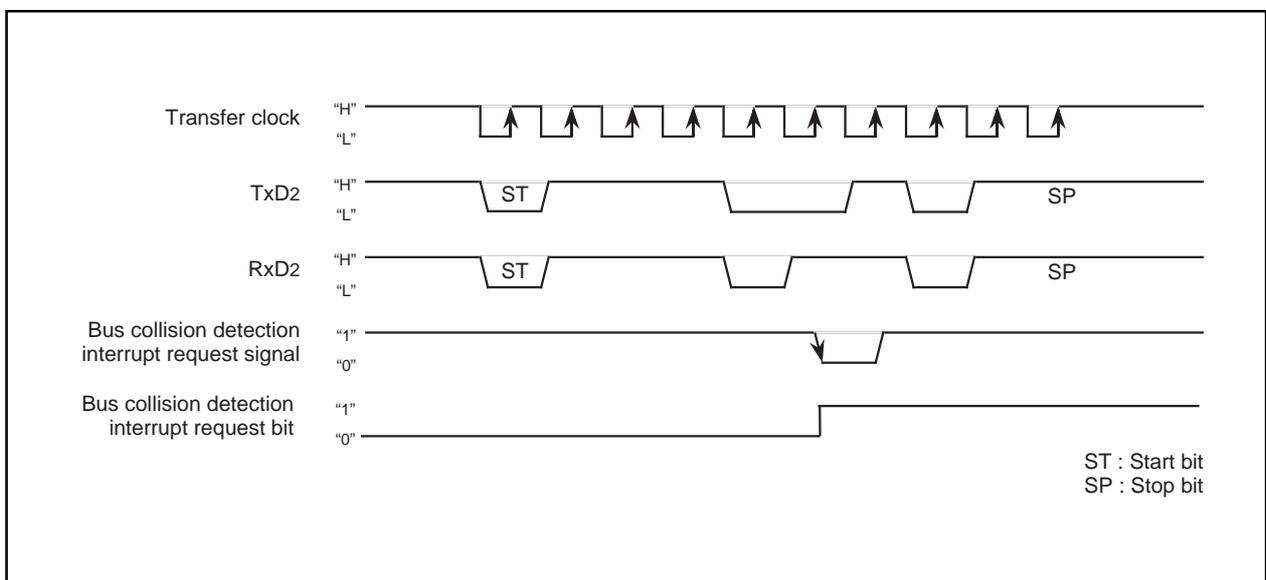

Figure 2.11.25 Detection timing of a bus collision (in UART mode)

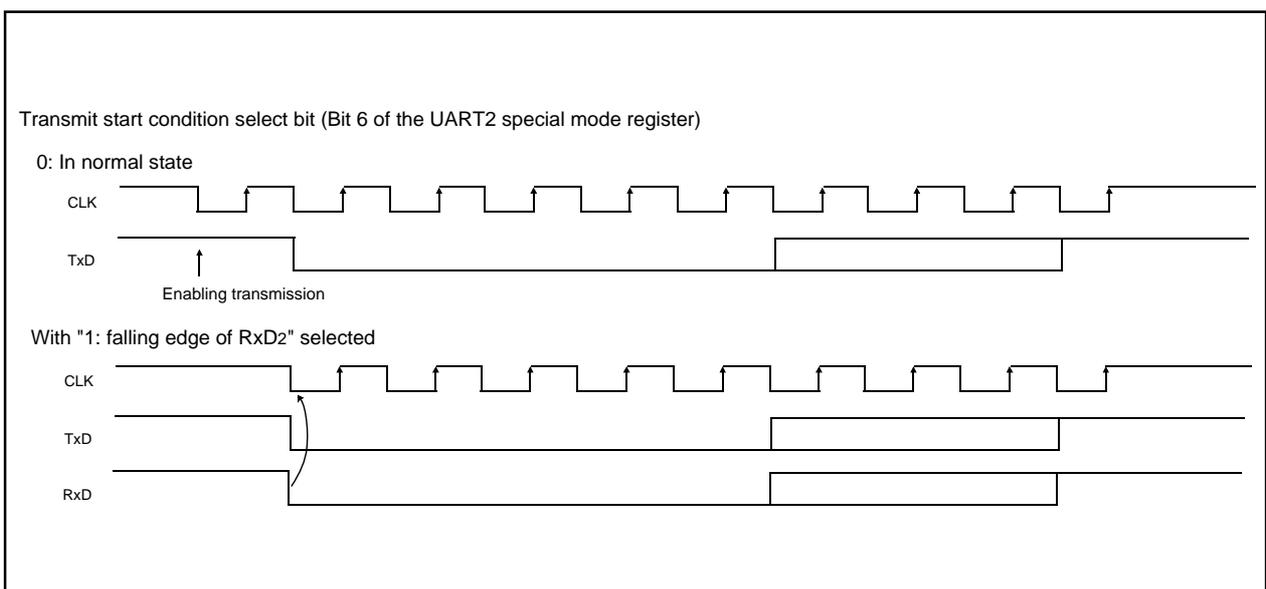

Figure 2.11.26 Some other functions

2.11.4 Clock-asynchronous Serial I/O Mode (Compliant with the SIM Interface)

The SIM interface is used for connecting the microcomputer with a memory card I/C or the like; adding some extra settings in UART2 clock-asynchronous serial I/O mode allows the user to effect this function. Tables 2.11.8 and 2.11.9 show the specifications of clock-asynchronous serial I/O mode (compliant with the SIM interface).

M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

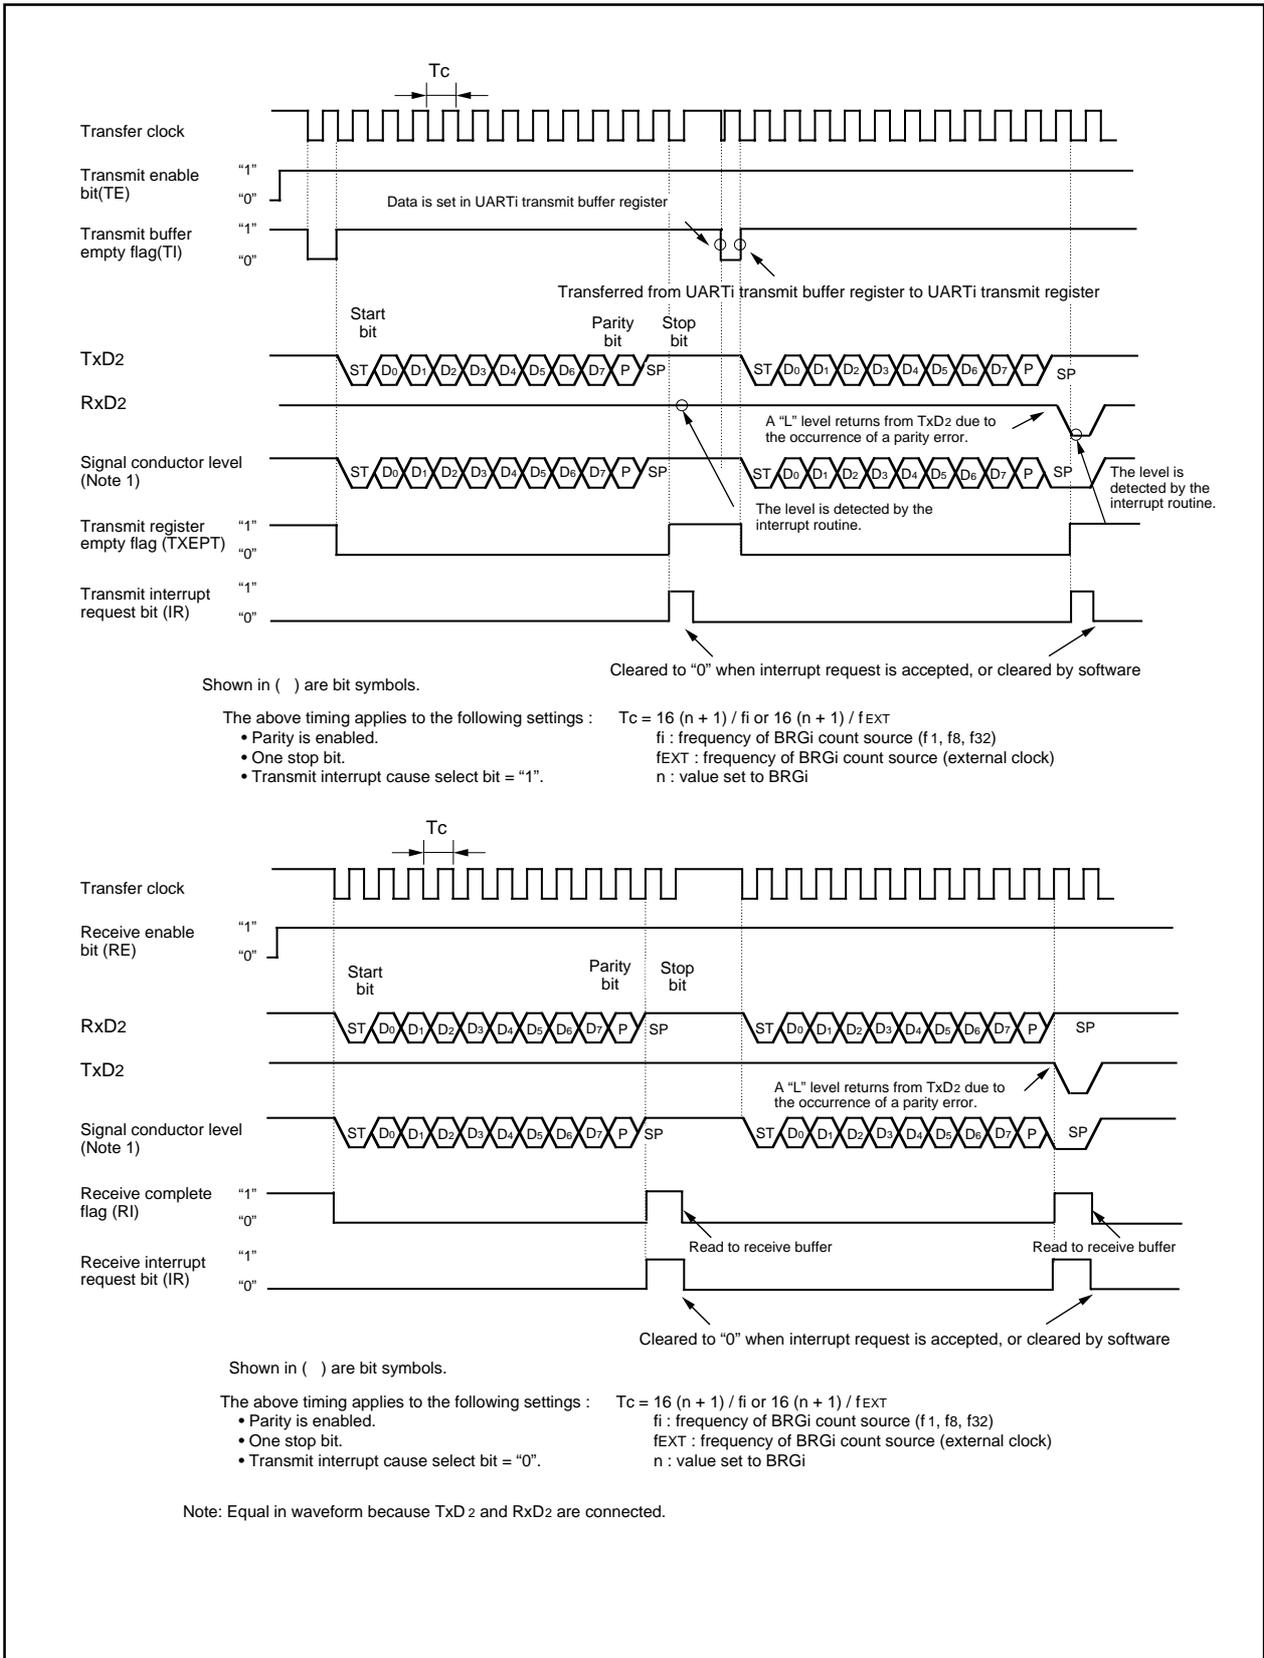

Figure 2.11.27 Typical transmit/receive timing in UART mode (compliant with the SIM interface)

(1) Function for outputting a parity error signal

With the error signal output enable bit (bit 7 of address 037D16) assigned "1", you can output an "L" level from the TxD2 pin when a parity error is detected. In step with this function, the generation timing of a transmission completion interrupt changes to the detection timing of a parity error signal. Figure 2.11.28 shows the output timing of the parity error signal.

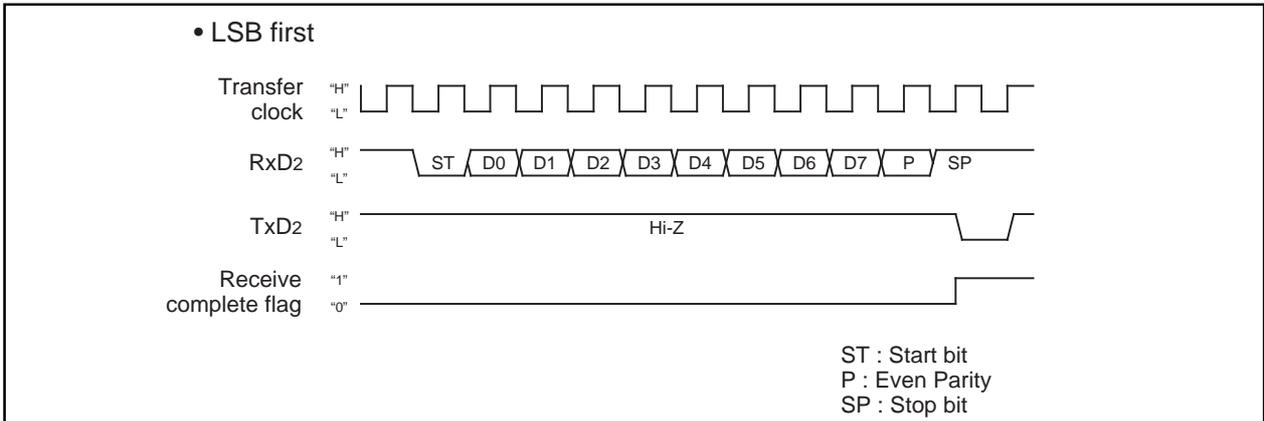

Figure 2.11.28 Output timing of the parity error signal

(2) Direct format/inverse format

Connecting the SIM card allows you to switch between direct format and inverse format. If you choose the direct format, D0 data is output from TxD2. If you choose the inverse format, D7 data is inverted and output from TxD2.

Figure 2.11.29 shows the SIM interface format.

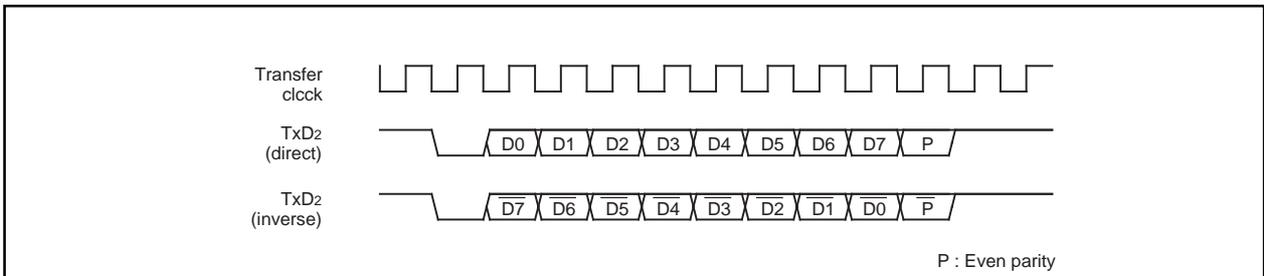

Figure 2.11.29 SIM interface format

Figure 2.11.30 shows the example of connecting the SIM interface. Connect TxD2 and RxD2 and apply pull-up.

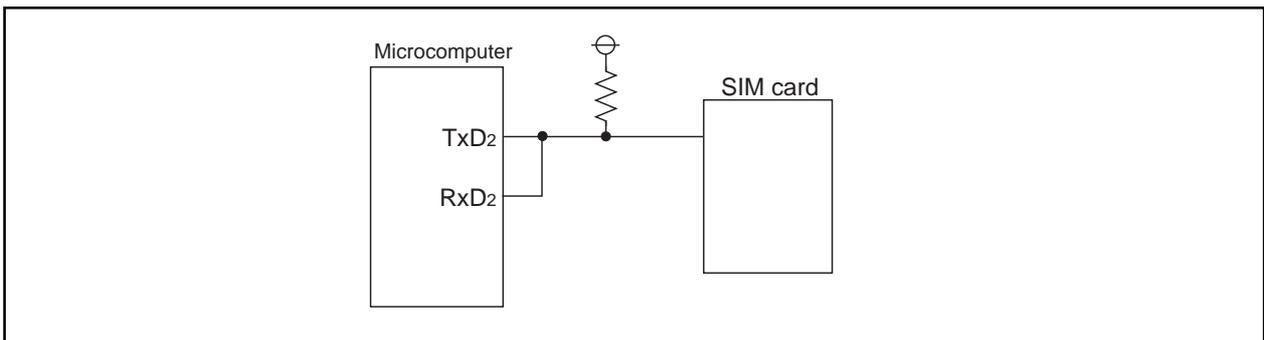

Figure 2.11.30 Connecting the SIM interface

2.11.5 Serial Interface Ports

The I/O ports (P67, P70 to P72) function as I/O ports of UART2 and multi-master I²C-BUS interface 0 (refer to “2.11.6 Multi-master I²C-BUS interface i”) . Set the connection between both serial interfaces and each port by bits 0 and 1 (BSEL0 and BSEL1) of the peripheral mode register (address 027D16) and bit 2 (FIICON) of the I²C0 port selection register (address 02E516).

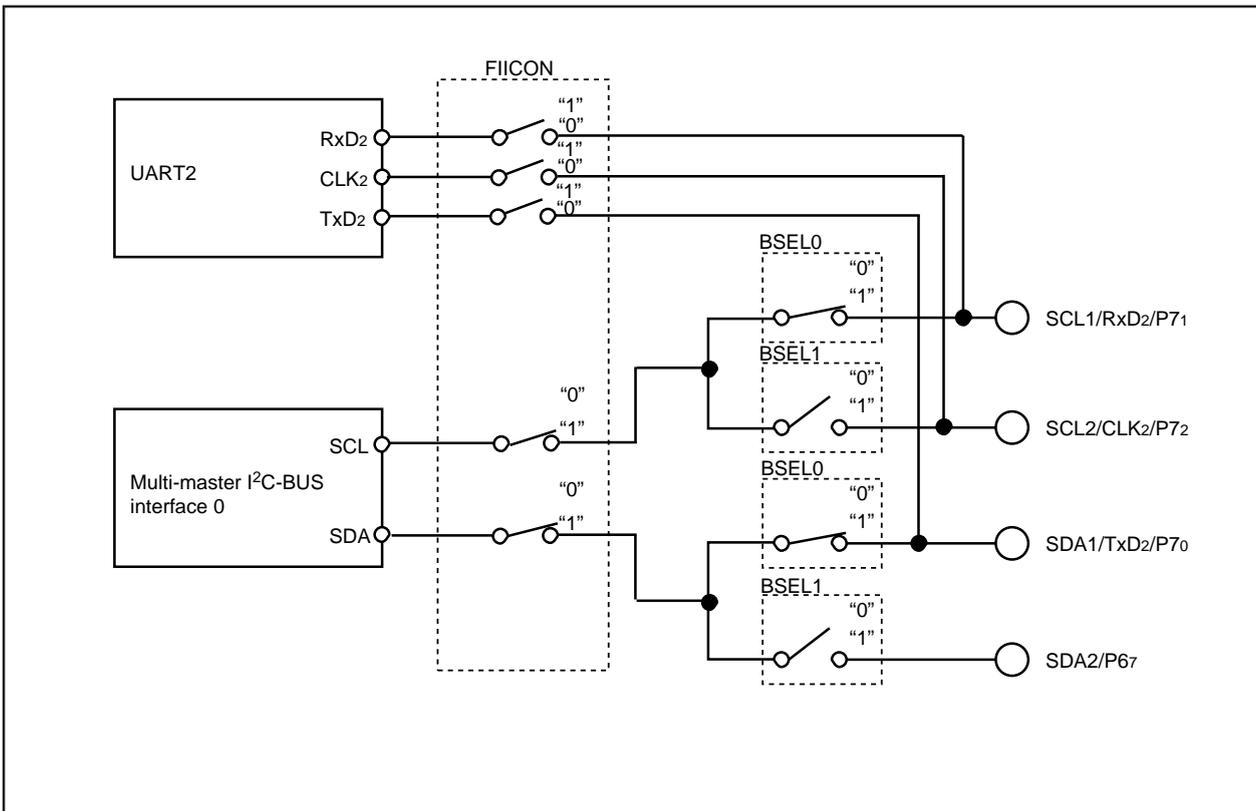

Figure 2.11.31 Serial interface port control

2.11.6 Multi-master I²C-BUS Interface 0 and Multi-master I²C-BUS Interface 1

The multi-master I²C-BUS interface 0 and 1 have each dedicated circuit and operate independently.

The multi-master I²C-BUS interface i is a serial communications circuit, conforming to the Philips I²C-BUS data transfer format. This interface i, offering both arbitration lost detection and a synchronous functions, is useful for the multi-master serial communications.

Figures 2.11.32 and Figure 2.11.33 show a block diagram of the multi-master I²C-BUS interface i and Table 2.11.13 shows multi-master I²C-BUS interface i functions.

This multi-master I²C-BUS interface i consists of the I²Ci address register, the I²Ci data shift register, the I²Ci clock control register, the I²Ci control register, the I²Ci status register, the I²Ci port selection register and other control circuits.

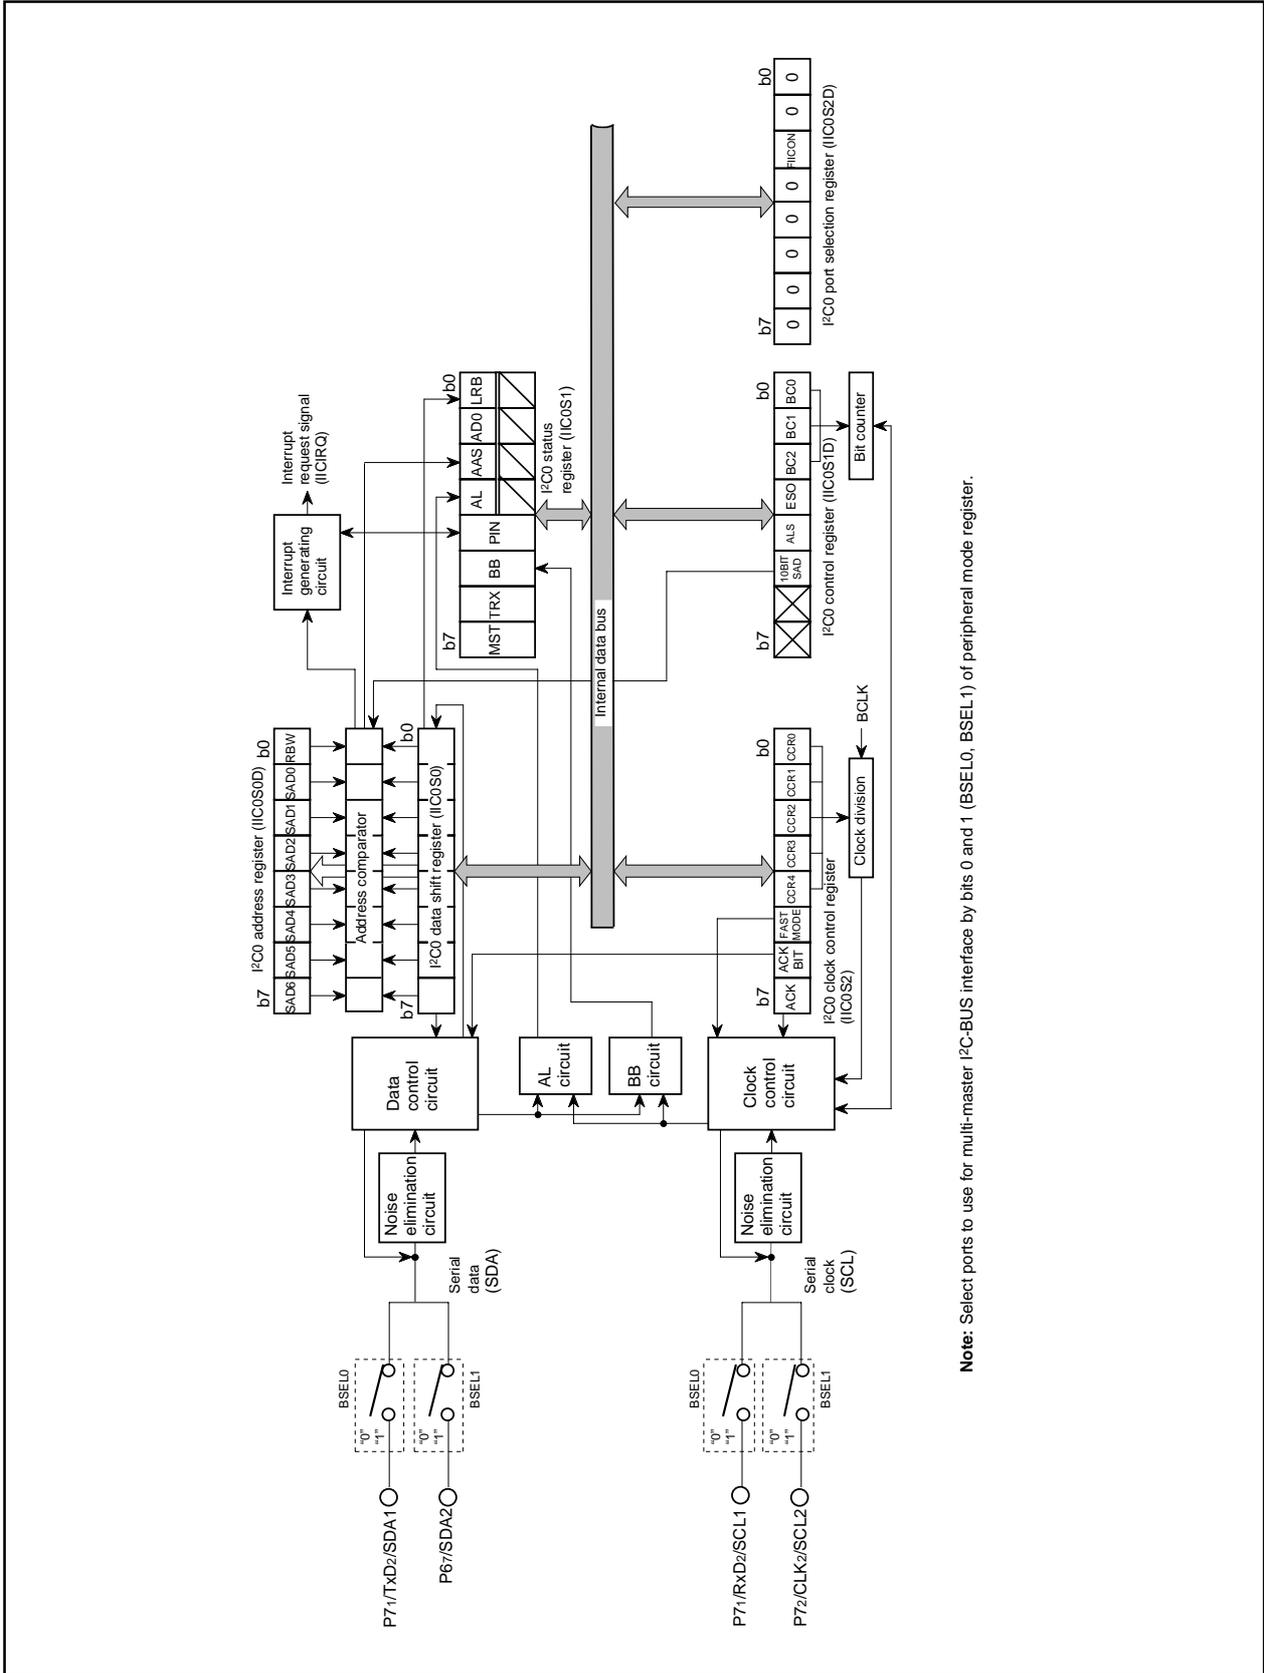

Table 2.11.13 Multi-master I²C-BUS Interface Functions

| Item | Function |
|----------------------|--|
| Format | In conformity with Philips I ² C-BUS standard: 10-bit addressing format 7-bit addressing format High-speed clock mode Standard clock mode |
| Communication mode | In conformity with Philips I ² C-BUS standard: Master transmission Master reception Slave transmission Slave reception |
| SCL clock frequencyn | 16.1 kHz to 400 kHz (at BCLK = 10 MHz) |

Note : We are not responsible for any third party's infringement of patent rights or other rights attributable to the use of the control function (bits 6 and 7 of the I²C control register at address 027D16) for connections between the I²C-BUS interface 0 and ports (SCL1, SCL2, SDA1, SDA2).

M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

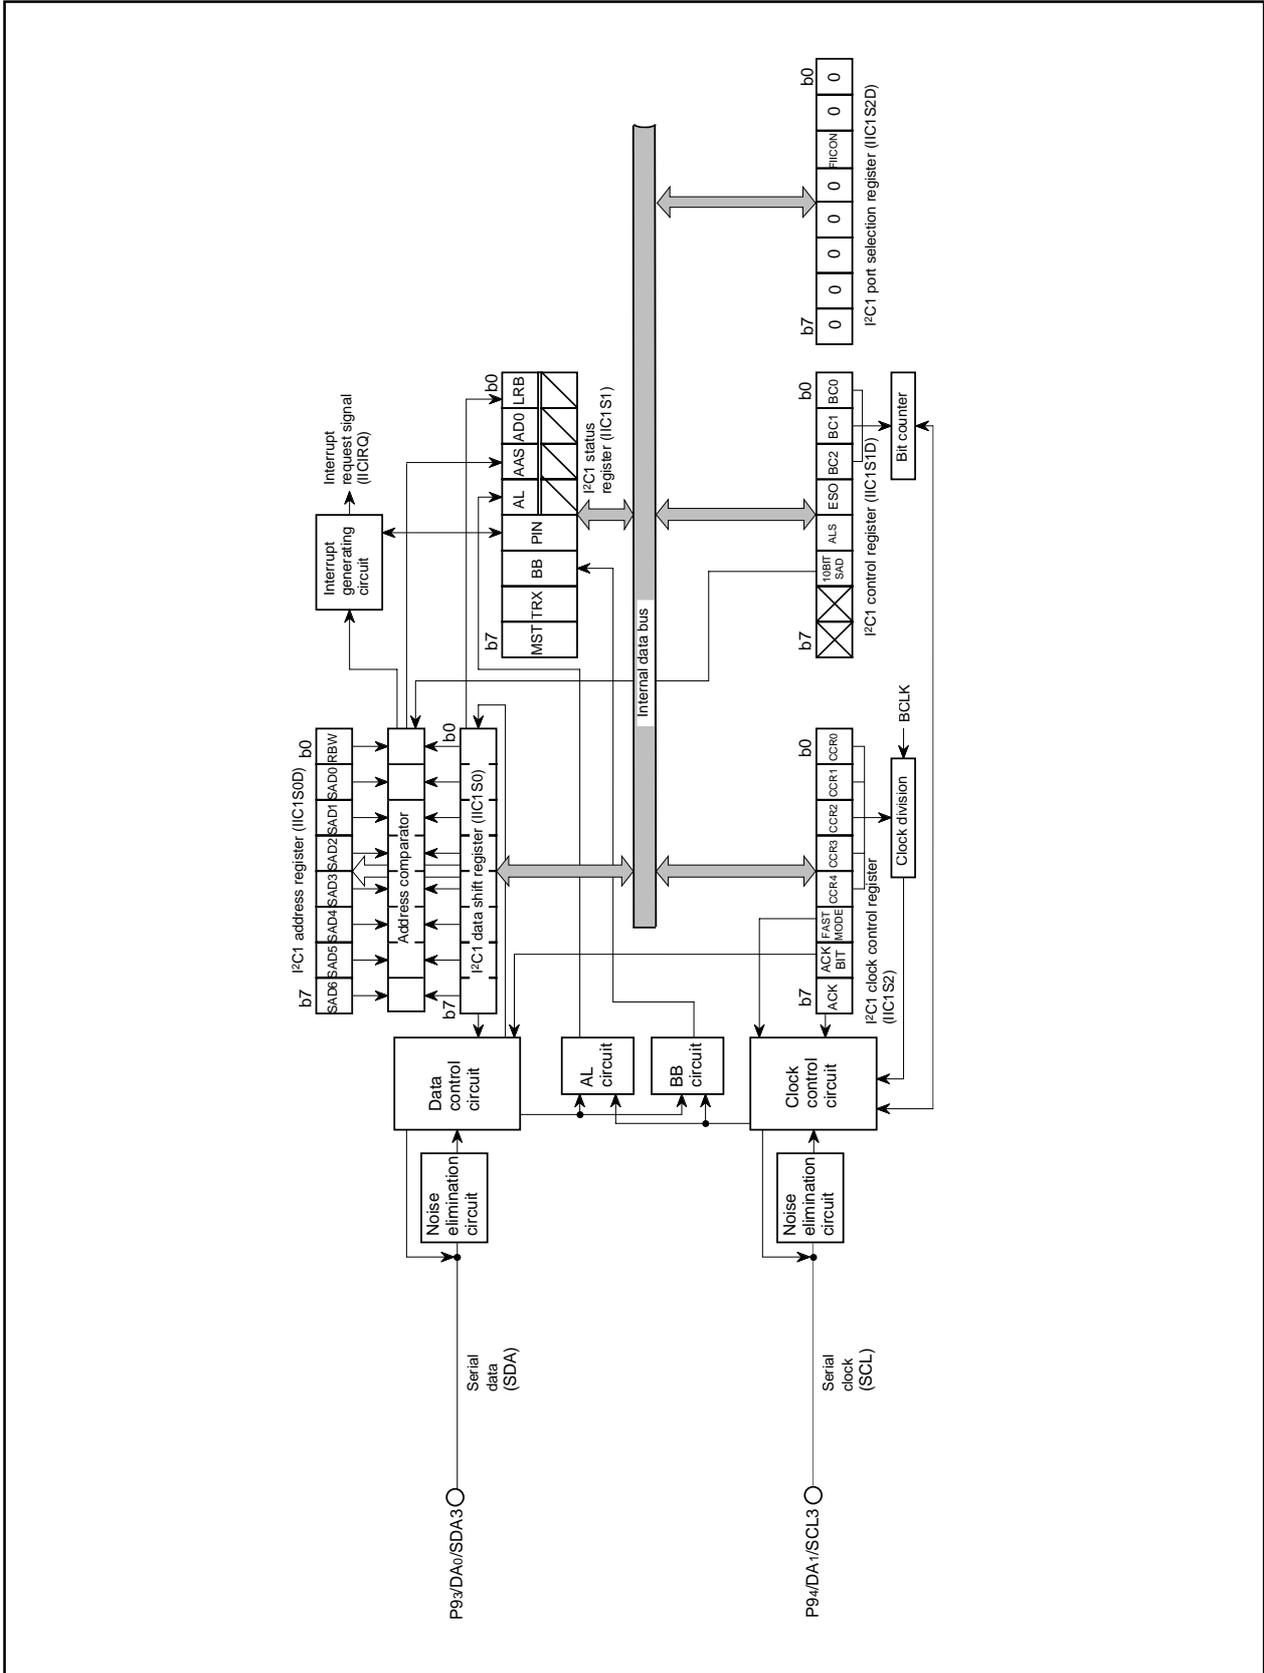

Fig. 2.11.33 Block Diagram of Multi-master I²C-BUS Interface 1

(1) I²C_i port selection register (i = 0, 1)

The I²C_i port selection register consists of bit to validate the multi-master I²C-BUS interface i function.

■ **Bit 2: Multi-master I²C-BUS interface valid bit (FIICON)**

When this bit is “0,” the multi-master I²C-BUS interface i is nonactive; when “1,” it is active. When selecting active, multi-master I²C-BUS interface 0 is connected with the ports selected by bits 0 and 1 of the peripheral mode register (address 027D₁₆) and multi-master I²C-BUS interface 1 is connected with the ports P9₃ and P9₄.

Note: It needs 10-BCLK cycles from setting this bit to “1” to being active of multi-master I²C-BUS interface i. Accordingly, do not access multi-master I²C-BUS interface i-related registers in this period.

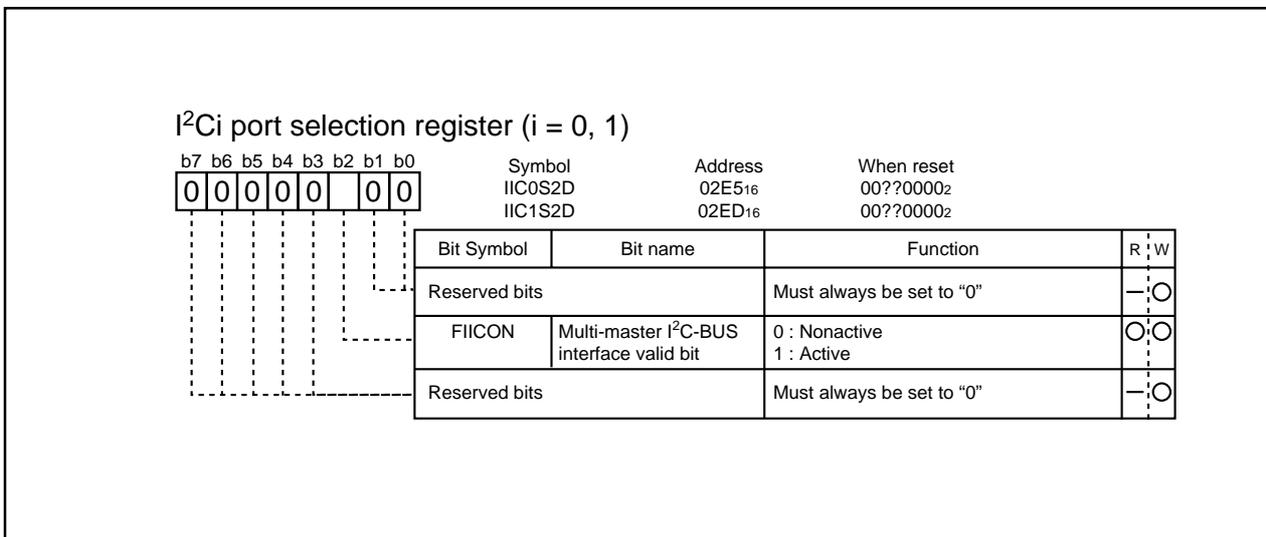

Fig. 2.11.34 I²C_i port selection register (i = 0, 1)

(2) I²Ci data shift register, I²Ci transmit buffer register (i = 0, 1)

The I²Ci data shift register is an 8-bit shift register to store receive data and write transmit data.

When transmit data is written into this register, it is transferred to the outside from bit 7 in synchronization with the SCL clock, and each time one-bit data is output, the data of this register are shifted one bit to the left. When data is received, it is input to this register from bit 0 in synchronization with the SCL clock, and each time one-bit data is input, the data of this register are shifted one bit to the left.

The I²Ci data shift register is in a write enable status only when the ESO bit of the I²Ci control register is "1." The bit counter is reset by a write instruction to the I²Ci data shift register. When both the ESO bit and the MST bit of the I²Ci status register are "1," the SCL is output by a write instruction to the I²Ci data shift register. Reading data from the I²Ci data shift register is always enabled regardless of the ESO bit value.

The I²Ci transmit buffer register is a register to store transmit data (slave address) to the I²Ci data shift register before RESTART condition generation. That is, in master, transmit data written to the I²Ci transmit buffer register is written to the I²Ci data shift register simultaneously. However, the SCL is not output. The I²Ci transmit buffer register can be written only when the ESO bit is "1," reading data from the I²Ci transmit buffer register is disabled regardless of the ESO bit value.

Notes 1: To write data into the I²Ci data shift register or the I²Ci transmit buffer register after the MST bit value changes from "1" to "0" (slave mode), keep an interval of 20 BCLK or more.

2: To generate START/RESTART condition after the I²Ci data shift register or the I²Ci transmit buffer register is written, keep an interval of 2 BCLK or more.

M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

(3) I²Ci address register (i = 0, 1)

The I²Ci address register consists of a 7-bit slave address and a $\overline{\text{read/write}}$ bit. In the addressing mode, the slave address written in this register is compared with the address data to be received immediately after the START condition are detected.

■ **Bit 0: $\overline{\text{read/write}}$ bit (RBW)**

Not used when comparing addresses, in the 7-bit addressing mode. In the 10-bit addressing mode, the first address data to be received is compared with the contents (SAD6 to SAD0 + RBW) of the I²Ci address register.

The RBW bit is cleared to "0" automatically when the stop condition is detected.

■ **Bits 1 to 7: slave address (SAD0–SAD6)**

These bits store slave addresses. Regardless of the 7-bit addressing mode and the 10-bit addressing mode, the address data transmitted from the master is compared with the contents of these bits.

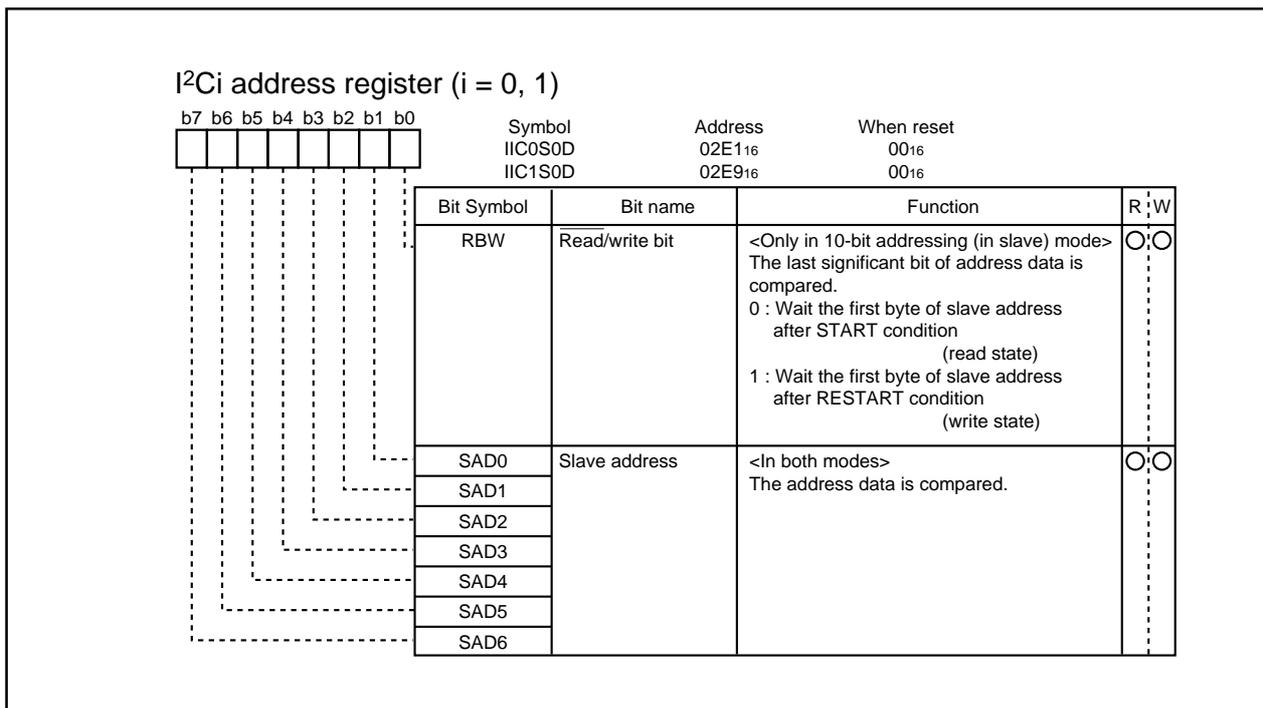

Fig. 2.11.37 I²Ci address register (i = 0, 1)

(4) I²Ci clock control register (i = 0, 1)

The I²Ci clock control register is used to set ACK control, SCL mode and SCL frequency.

■ Bits 0 to 4: SCL frequency control bits (CCR0–CCR4)

These bits control the SCL frequency.

■ Bit 5: SCL mode specification bit (FAST MODE)

This bit specifies the SCL mode. When this bit is set to “0,” the standard clock mode is set. When the bit is set to “1,” the high-speed clock mode is set.

■ Bit 6: ACK bit (ACK BIT)

This bit sets the SDA status when an ACK clock* is generated. When this bit is set to “0,” the ACK return mode is set and SDA goes to LOW at the occurrence of an ACK clock. When the bit is set to “1,” the ACK non-return mode is set. The SDA is held in the HIGH status at the occurrence of an ACK clock.

However, when the slave address matches the address data in the reception of address data at ACK BIT = “0,” the SDA is automatically made LOW (ACK is returned). If there is a mismatch between the slave address and the address data, the SDA is automatically made HIGH (ACK is not returned).

*ACK clock: Clock for acknowledgement

■ Bit 7: ACK clock bit (ACK)

This bit specifies a mode of acknowledgment which is an acknowledgment response of data transmission. When this bit is set to “0,” the no ACK clock mode is set. In this case, no ACK clock occurs after data transmission. When the bit is set to “1,” the ACK clock mode is set and the master generates an ACK clock upon completion of each 1-byte data transmission. The device for transmitting address data and control data releases the SDA at the occurrence of an ACK clock (make SDA HIGH) and receives the ACK bit generated by the data receiving device.

Note: Do not write data into the I²Ci clock control register during transmission. If data is written during transmission, the I²Ci clock generator is reset, so that data cannot be transmitted normally.

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

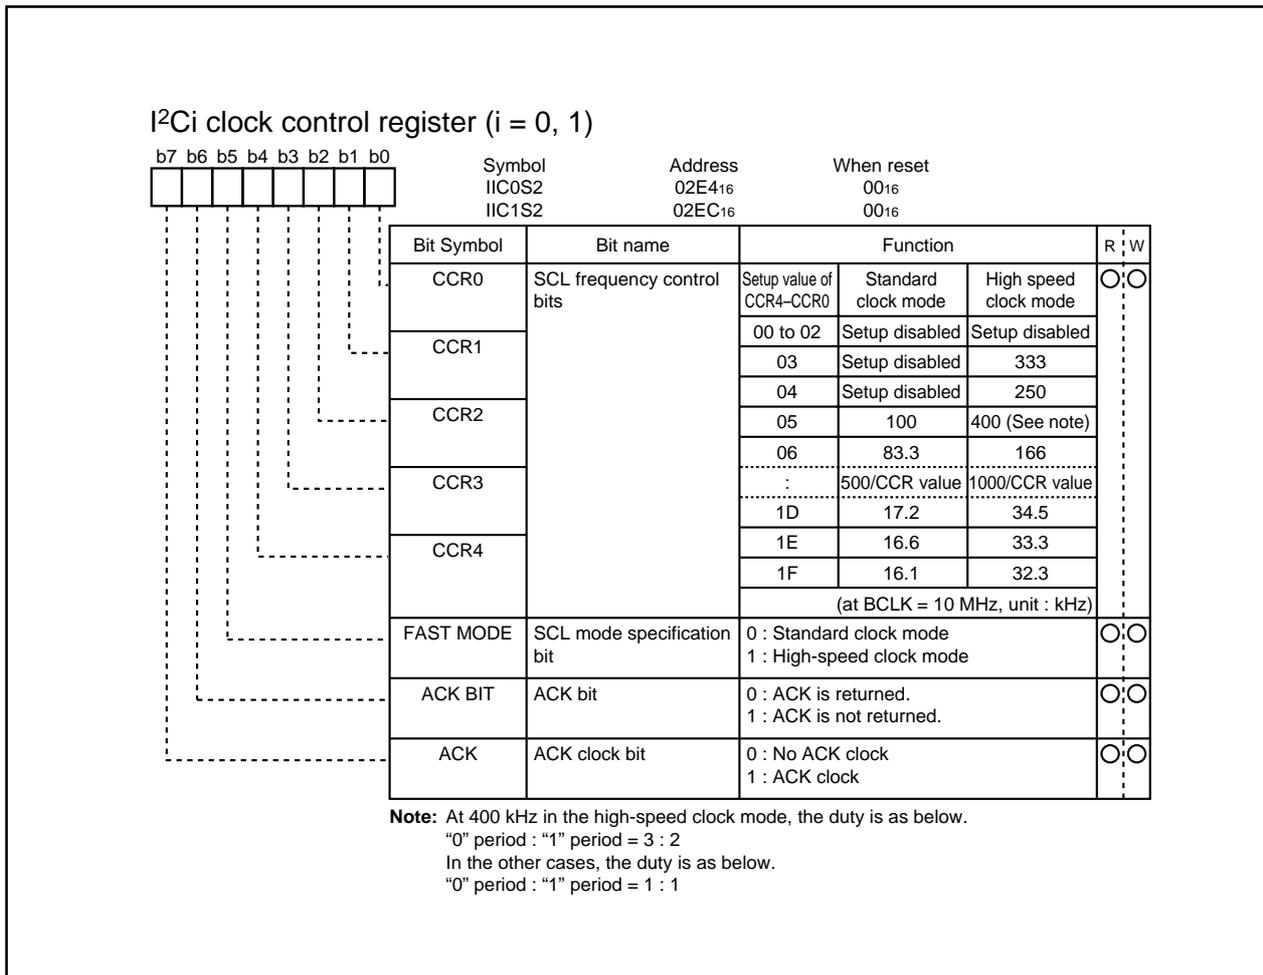

Fig. 2.11.38 I²Ci clock control register (i = 0, 1)

(5) I²C_i control register (i = 0, 1)

The I²C_i control register controls the data communication format.

■ Bits 0 to 2: bit counter (BC0–BC2)

These bits decide the number of bits for the next 1-byte data to be transmitted. An interrupt request signal occurs immediately after the number of bits specified with these bits are transmitted.

When a START condition is received, these bits become “000₂” and the address data is always transmitted and received in 8 bits.

Note: When the bit counter value = “111₂,” a STOP condition and START condition cannot be waited.

■ Bit 3: I²C-BUS interface i use enable bit (ESO)

This bit enables usage of the multimaster I²C-BUS interface i. When this bit is set to “0,” the use disable status is provided, so the SDA and the SCL become high-impedance. When the bit is set to “1,” use of the interface is enabled.

When ESO = “0,” the following is performed.

- PIN = “1,” BB = “0” and AL = “0” are set (they are bits of the I²C_i status register).
- Writing data to the I²C_i data shift register and the I²C_i transmit buffer register is disabled.

■ Bit 4: data format selection bit (ALS)

This bit decides whether or not to recognize slave addresses. When this bit is set to “0,” the addressing format is selected, so that address data is recognized. When a match is found between a slave address and address data as a result of comparison or when a general call (refer to “(6) I²C_i status register,” bit 1) is received, transmission processing can be performed. When this bit is set to “1,” the free data format is selected, so that slave addresses are not recognized.

■ Bit 5: addressing format selection bit (10BIT SAD)

This bit selects a slave address specification format. When this bit is set to “0,” the 7-bit addressing format is selected. In this case, only the high-order 7 bits (slave address) of the I²C_i address register are compared with address data. When this bit is set to “1,” the 10-bit addressing format is selected, all the bits of the I²C_i address register are compared with address data.

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

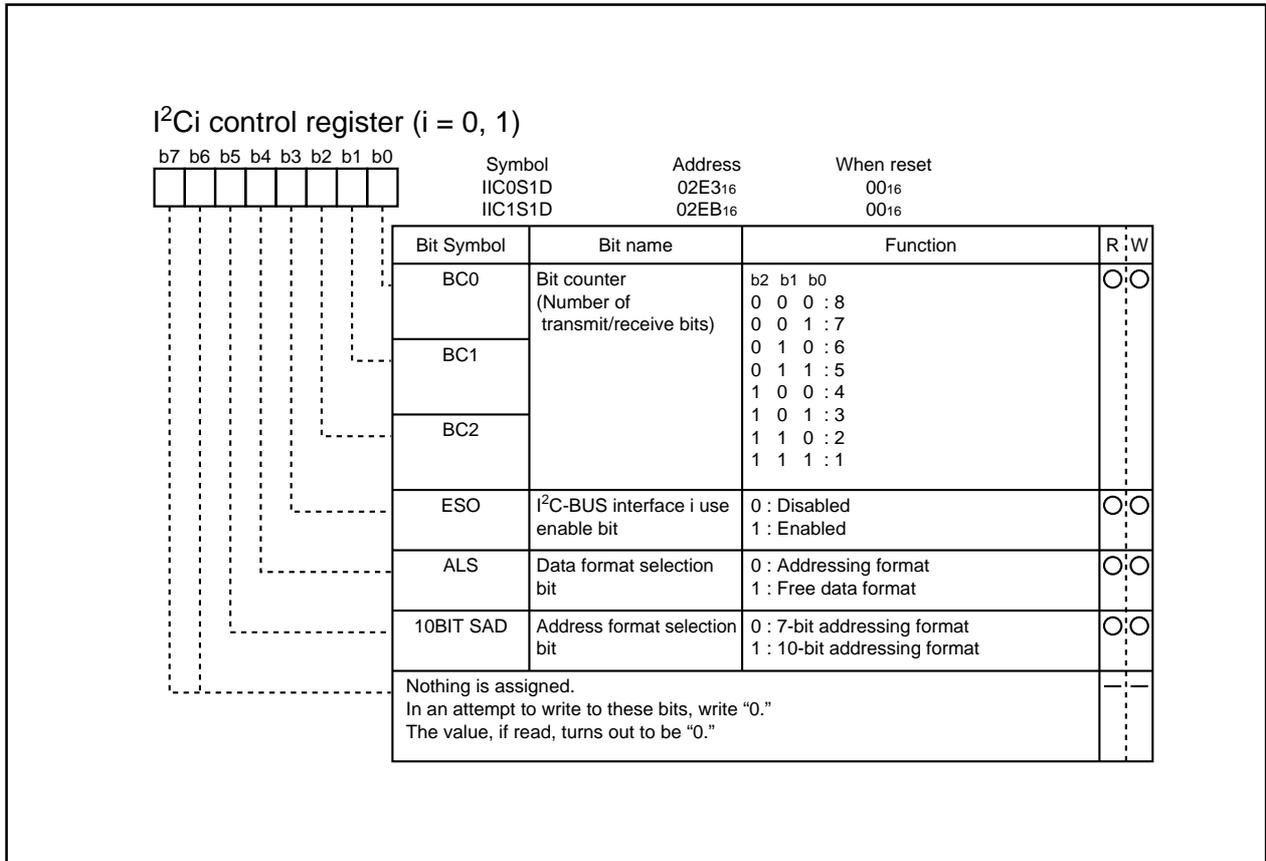

Fig. 2.11.39 I²Ci control register (i = 0, 1)

(6) I²Ci status register (i = 0, 1)

The I²Ci status register controls the I²C-BUS interface i status. Bits 0 to 3, 5 are read-only bits and bits 4, 6, 7 can be read out and written to.

■ Bit 0: last receive bit (LRB)

This bit stores the last bit value of received data and can also be used for ACK receive confirmation. If ACK is returned when an ACK clock occurs, the LRB bit is set to "0." If ACK is not returned, this bit is set to "1." Except in the ACK mode, the last bit value of received data is input. The state of this bit is changed from "1" to "0" by executing a write instruction to the I²Ci data shift register or the I²Ci transmit buffer register.

■ Bit 1: general call detecting flag (AD0)

This bit is set to "1" when a general call* whose address data is all "0" is received in the slave mode. By a general call of the master device, every slave device receives control data after the general call. The AD0 bit is set to "0" by detecting the STOP condition or START condition.

*General call: The master transmits the general call address "00₁₆" to all slaves.

■ Bit 2: slave address comparison flag (AAS)

This flag indicates a comparison result of address data.

<<In the slave receive mode, when the 7-bit addressing format is selected, this bit is set to "1" in one of the following conditions.>>

- The address data immediately after occurrence of a START condition matches the slave address stored in the high-order 7 bits of the I²Ci address register.
- A general call is received.

<<In the slave reception mode, when the 10-bit addressing format is selected, this bit is set to "1" with the following condition.>>

- When the address data is compared with the I²Ci address register (8 bits consists of slave address and RBW), the first bytes match.

<<The state of this bit is changed from "1" to "0" by executing a write instruction to the I²Ci data shift register or the I²Ci transmit buffer register.>>

■ Bit 3: arbitration lost* detecting flag (AL)

In the master transmission mode, when a device other than the microcomputer sets the SDA to "L," arbitration is judged to have been lost, so that this bit is set to "1." At the same time, the TRX bit is set to "0," so that immediately after transmission of the byte whose arbitration was lost is completed, the MST bit is set to "0." When arbitration is lost during slave address transmission, the TRX bit is set to "0" and the reception mode is set. Consequently, it becomes possible to receive and recognize its own slave address transmitted by another master device.

*Arbitration lost: The status in which communication as a master is disabled.

■ Bit 4: I²C-BUS interface i interrupt request bit (PIN)

This bit generates an interrupt request signal. Each time 1-byte data is transmitted, the state of the PIN bit changes from “1” to “0.” At the same time, an interrupt request signal is sent to the CPU. The PIN bit is set to “0” in synchronization with a falling edge of the last clock (including the ACK clock) of an internal clock and an interrupt request signal occurs in synchronization with a falling edge of the PIN bit. When detecting the STOP condition in slave, the multi-master I²C-BUS interface interrupt request bit (IR) is set to “1” (interrupt requested) regardless of falling of PIN bit. When the PIN bit is “0,” the SCL is kept in the “0” state and clock generation is disabled. Figure 2.11.41 shows an interrupt request signal generating timing chart.

The PIN bit is set to “1” in any one of the following conditions.

- Writing “1” to the PIN bit
- Executing a write instruction to the I²Ci data shift register or the I²Ci transmit buffer register (See note).
- When the ESO bit is “0”
- At reset

Note : It takes 8 BCLK cycles or more until PIN bit becomes “1” after write instructions are executed to these registers.

The conditions in which the PIN bit is set to “0” are shown below:

- Immediately after completion of 1-byte data transmission (including when arbitration lost is detected)
- Immediately after completion of 1-byte data reception
- In the slave reception mode, with ALS = “0” and immediately after completion of slave address or general call address reception
- In the slave reception mode, with ALS = “1” and immediately after completion of address data reception

■ Bit 5: bus busy flag (BB)

This bit indicates the status of use of the bus system. When this bit is set to “0,” this bus system is not busy and a START condition can be generated. When this bit is set to “1,” this bus system is busy and the occurrence of a START condition is disabled by the START condition duplication prevention function (See note).

This flag can be written by software only in the master transmission mode. In the other modes, this bit is set to “1” by detecting a START condition and set to “0” by detecting a STOP condition. When the ESO bit of the I²Ci control register is “0” and at reset, the BB flag is kept in the “0” state.

■ Bit 6: communication mode specification bit (transfer direction specification bit: TRX)

This bit decides the direction of transfer for data communication. When this bit is “0,” the reception mode is selected and the data of a transmitting device is received. When the bit is “1,” the transmission mode is selected and address data and control data are output into the SDA in synchronization with the clock generated on the SCL.

When the ALS bit of the I²Ci control register is “0” in the slave reception mode is selected, the TRX bit is set to “1” (transmit) if the least significant bit (R/ \bar{W} bit) of the address data transmitted by the master is “1.” When the ALS bit is “0” and the R/ \bar{W} bit is “0,” the TRX bit is cleared to “0” (receive).

The TRX bit is cleared to “0” in one of the following conditions.

- When arbitration lost is detected.
- When a STOP condition is detected.
- When occurrence of a START condition is disabled by the START condition duplication prevention function (Note).
- With MST = “0” and when a START condition is detected.
- With MST = “0” and when ACK non-return is detected.
- At reset

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

■ **Bit 7: Communication mode specification bit (master/slave specification bit: MST)**

This bit is used for master/slave specification for data communication. When this bit is “0,” the slave is specified, so that a START condition and a STOP condition generated by the master are received, and data communication is performed in synchronization with the clock generated by the master. When this bit is “1,” the master is specified and a START condition and a STOP condition are generated, and also the clocks required for data communication are generated on the SCL.

The MST bit is cleared to “0” in one of the following conditions.

- Immediately after completion of 1-byte data transmission when arbitration lost is detected
- When a STOP condition is detected.
- When occurrence of a START condition is disabled by the START condition duplication preventing function (See note).
- At reset

Note: The START condition duplication prevention function disables the following: the START condition generation; bit counter reset, and SCL output with the generation. This bit is valid from setting of BB flag to the completion of 1-byte transmission/reception (occurrence of transmission/reception interrupt request) <IICIRQ>.

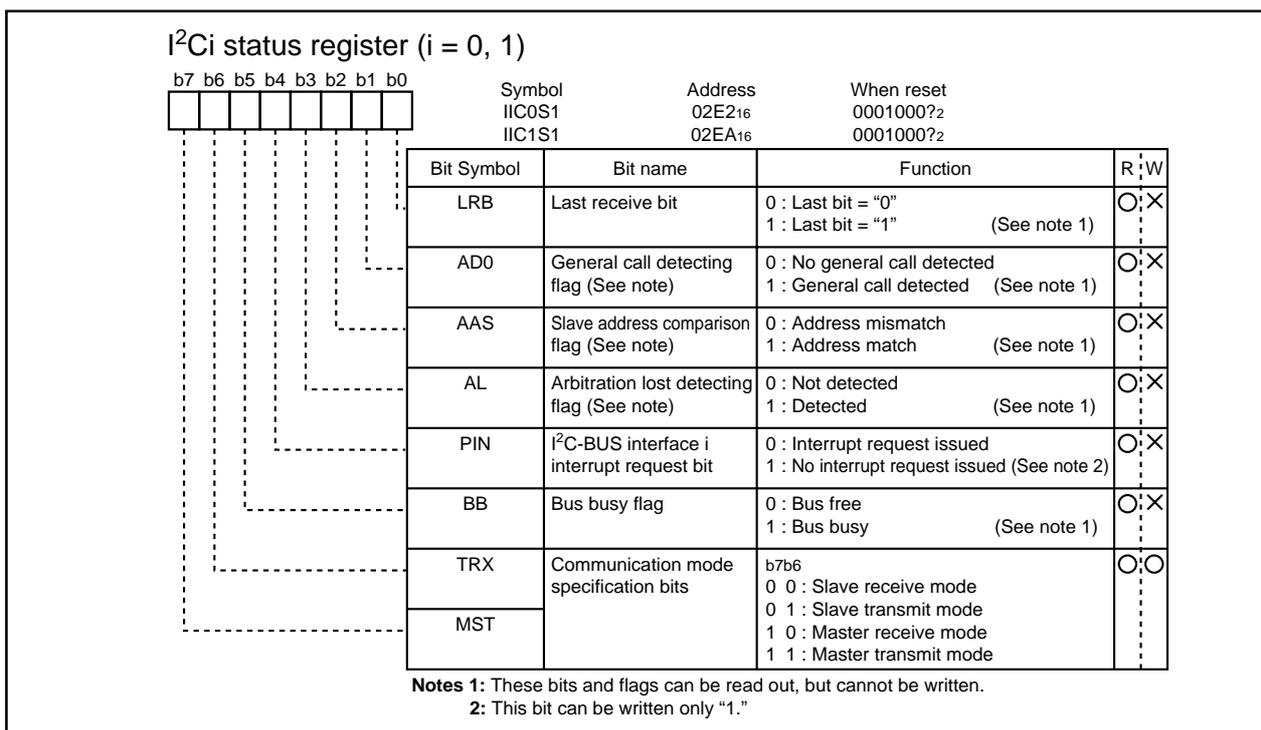

Fig. 2.11.40 I²Ci status register (i = 0, 1)

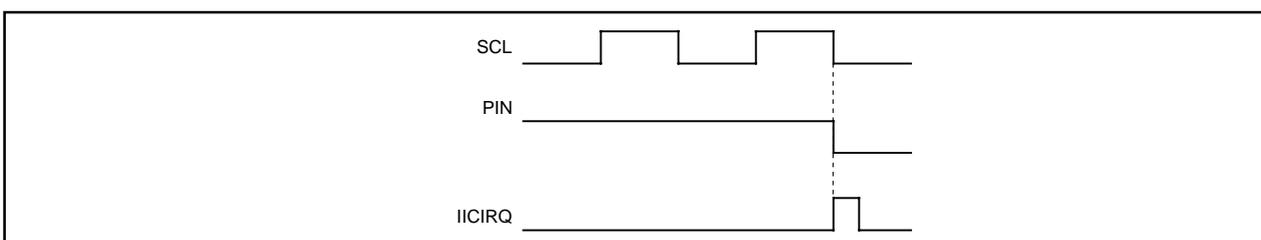

Fig. 2.11.41 Interrupt request signal generation timing

(7) START condition generation method

When the ESO bit of the I²Ci control register is “1,” execute a write instruction to the I²Ci status register to set the MST, TRX and BB bits to “1.” A START condition will then be generated. After that, the bit counter becomes “0002” and an SCL for 1 byte is output. The START condition generation timing and BB bit set timing are different in the standard clock mode and the high-speed clock mode. Refer to Figure 2.11.42 for the START condition generation timing diagram, and Table 2.11.13 for the START condition/STOP condition generation timing table.

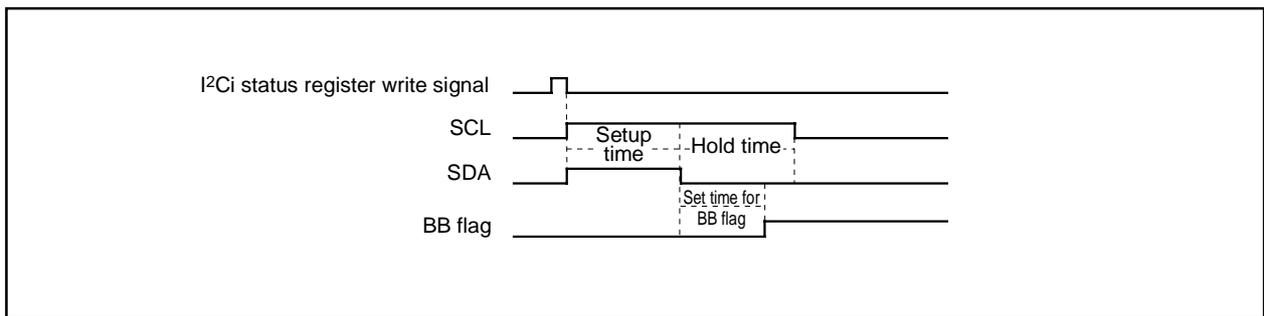

Fig. 2.11.42 START condition generation timing diagram

(8) STOP condition generation method

When the ESO bit of the I²Ci control register is “1,” execute a write instruction to the I²Ci status register for setting the MST bit and the TRX bit to “1” and the BB bit to “0”. A STOP condition will then be generated. The STOP condition generation timing and the BB flag reset timing are different in the standard clock mode and the high-speed clock mode. Refer to Figure 2.11.43 for the STOP condition generation timing diagram, and Table 2.11.13 for the START condition/STOP condition generation timing table.

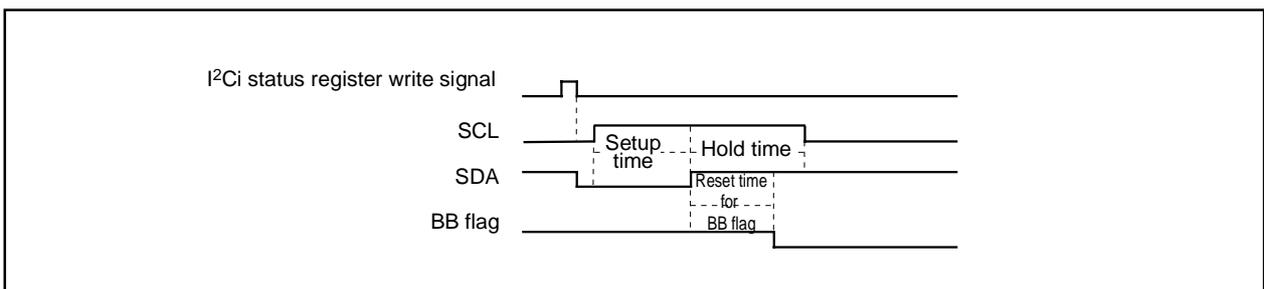

Fig. 2.11.43 STOP condition generation timing diagram

Table 2.11.13 START condition/STOP condition generation timing table

| Item | Standard Clock Mode | High-speed Clock Mode |
|----------------------------|-----------------------|-----------------------|
| Setup time | 5.35 μs (53.5 cycles) | 1.85 μs (18.5 cycles) |
| Hold time | 4.9 μs (49 cycles) | 2.4 μs (24 cycles) |
| Set/reset time for BB flag | 3.75 μs (37.5 cycles) | 0.85 μs (8.5 cycles) |

Note: Absolute time at BCLK = 10 MHz. The value in parentheses denotes the number of BCLK cycles.

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

(9) START/STOP condition detect conditions

The START/STOP condition detect conditions are shown in Figure 2.11.44 and Table 2.11.14. Only when the 3 conditions of Table 2.11.14 are satisfied, a START/STOP condition can be detected.

Note: When a STOP condition is detected in the slave mode (MST = 0), an interrupt request signal <IICIRQ> is generated to the CPU.

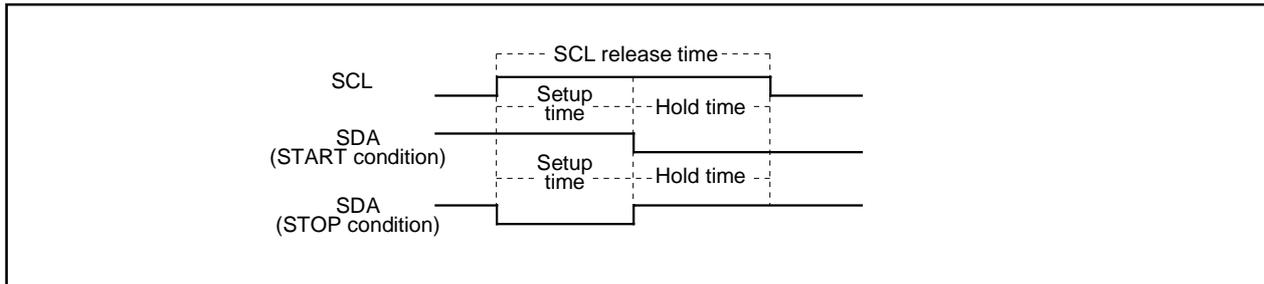

Fig. 2.11.44 START condition/STOP condition detect timing diagram

Table 2.11.14 START condition/STOP condition detect conditions

| Standard Clock Mode | High-speed Clock Mode |
|---------------------------------------|---------------------------------------|
| 6.5 μs (65 cycles) < SCL release time | 1.0 μs (10 cycles) < SCL release time |
| 3.25 μs (32.5 cycles) < Setup time | 0.5 μs (5 cycles) < Setup time |
| 3.25 μs (32.5 cycles) < Hold time | 0.5 μs (5 cycles) < Hold time |

Note: Absolute time at BCLK = 10 MHz. The value in parentheses denotes the number of BCLK cycles.

(10) Address data communication

There are two address data communication formats, namely, 7-bit addressing format and 10-bit addressing format. The respective address communication formats is described below.

■ 7-bit addressing format

To meet the 7-bit addressing format, set the 10BIT SAD bit of the I²Ci control register to "0." The first 7-bit address data transmitted from the master is compared with the high-order 7-bit slave address stored in the I²Ci address register. At the time of this comparison, address comparison of the RBW bit of the I²Ci address register is not made. For the data transmission format when the 7-bit addressing format is selected, refer to Figure 2.11.45, (1) and (2).

■ 10-bit addressing format

To meet the 10-bit addressing format, set the 10BIT SAD bit of the I²Ci control register to "1." An address comparison is made between the first-byte address data transmitted from the master and the 7-bit slave address stored in the I²Ci address register. At the time of this comparison, an address comparison between the RBW bit of the I²Ci address register and the R \bar{W} bit which is the last bit of the address data transmitted from the master is made. In the 10-bit addressing mode, the R \bar{W} bit which is the last bit of the address data not only specifies the direction of communication for control data but also is processed as an address data bit.

When the first-byte address data matches the slave address, the AAS bit of the I²Ci status register is set to "1." After the second-byte address data is stored into the I²Ci data shift register, make an address comparison between the second-byte data and the slave address by software. When the address data of the 2nd bytes matches the slave address, set the RBW bit of the I²Ci address register to "1" by software. This processing can match the 7-bit slave address and R \bar{W} data, which are received after a RESTART condition is detected, with the value of the I²Ci address register. For the data transmission format when the 10-bit addressing format is selected, refer to Figure 2.11.45, (3) and (4).

(11) Example of Master Transmission

An example of master transmission in the standard clock mode, at the SCL frequency of 100 kHz and in the ACK return mode is shown below.

- ① Set a slave address in the high-order 7 bits of the I²Ci address register and "0" in the RBW bit.
- ② Set the ACK return mode and SCL = 100 kHz by setting "85₁₆" in the I²Ci clock control register.
- ③ Set "10₁₆" in the I²Ci status register and hold the SCL at the HIGH.
- ④ Set a communication enable status by setting "08₁₆" in the I²Ci control register.
- ⑤ Set the address data of the destination of transmission in the high-order 7 bits of the I²Ci data shift register and set "0" in the least significant bit.
- ⑥ Set "F0₁₆" in the I²Ci status register to generate a START condition. At this time, an SCL for 1 byte and an ACK clock automatically occurs.
- ⑦ Set transmit data in the I²Ci data shift register. At this time, an SCL and an ACK clock automatically occurs.
- ⑧ When transmitting control data of more than 1 byte, repeat step ⑦.
- ⑨ Set "D0₁₆" in the I²Ci status register. After this, if ACK is not returned or transmission ends, a STOP condition will be generated.

(12) Example of Slave Reception

An example of slave reception in the high-speed clock mode, at the SCL frequency of 400 kHz, in the ACK non-return mode, using the addressing format, is shown below.

- ① Set a slave address in the high-order 7 bits of the I²Ci address register and "0" in the RBW bit.
- ② Set the no ACK clock mode and SCL = 400 kHz by setting "25₁₆" in the I²Ci clock control register.
- ③ Set "10₁₆" in the I²Ci status register and hold the SCL at the HIGH.
- ④ Set a communication enable status by setting "08₁₆" in the I²Ci control register.
- ⑤ When a START condition is received, an address comparison is made.
- ⑥
 - When all transmitted address are "0" (general call):
AD0 of the I²Ci status register is set to "1" and an interrupt request signal occurs.
 - When the transmitted addresses match the address set in ①:
ASS of the I²Ci status register is set to "1" and an interrupt request signal occurs.
 - In the cases other than the above:
AD0 and AAS of the I²Ci status register are set to "0" and no interrupt request signal occurs.
- ⑦ Set dummy data in the I²Ci data shift register.
- ⑧ When receiving control data of more than 1 byte, repeat step ⑦.
- ⑨ When a STOP condition is detected, the communication ends.

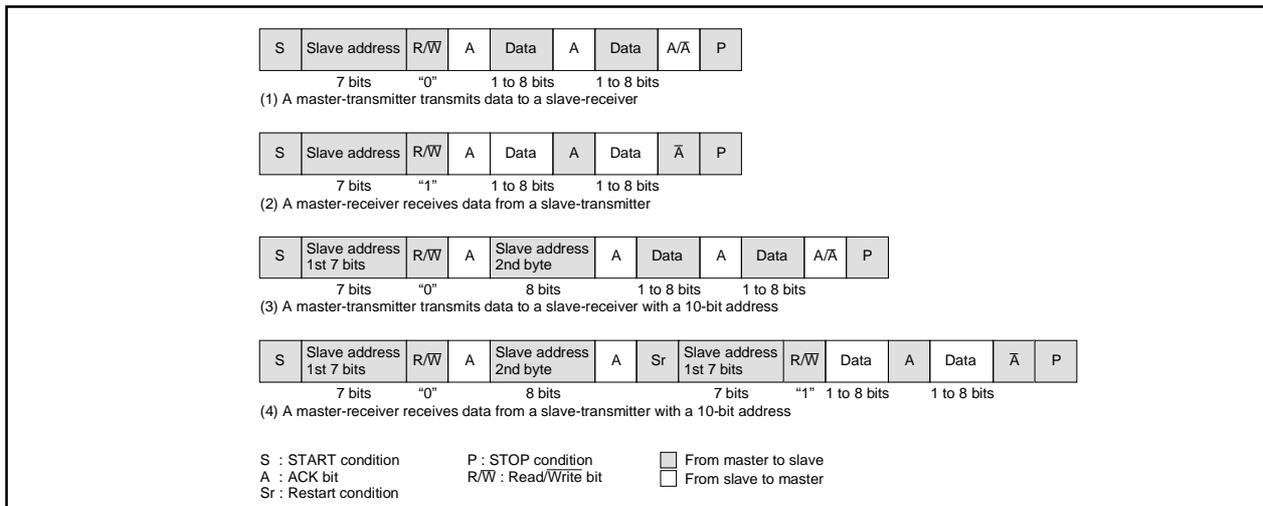

Fig. 2.11.45 Address data communication format

(13) Precautions when using multi-master I²C-BUS interface i

■ BCLK operation mode

Select the no-division mode and set the main clock frequency to $f(XIN) = 10 \text{ MHz}$.

■ Used instructions

Specify byte (.B) as data size to access multi-master I²C-BUS interface i-related registers.

■ Read-modify-write instruction

The precautions when the read-modify-write instruction such as BSET, BCLR etc. is executed for each register of the multi-master I²C-BUS interface are described below.

• I²Ci data shift register (IICiS0)

When executing the read-modify-write instruction for this register during transfer, data may become a value not intended.

• I²Ci address register (IICiS0D)

When the read-modify-write instruction is executed for this register at detecting the STOP condition, data may become a value not intended. It is because hardware changes the read/write bit (RBW) at the above timing.

• I²Ci status register (IICiS1)

Do not execute the read-modify-write instruction for this register because all bits of this register are changed by hardware.

• I²Ci control register (IICiS1D)

When the read-modify-write instruction is executed for this register at detecting the START condition or at completing the byte transfer, data may become a value not intended. Because hardware changes the bit counter (BC0–BC2) at the above timing.

• I²Ci clock control register (IICiS2)

The read-modify-write instruction can be executed for this register.

• I²Ci port selection register (IICiS2D)

Since the read value of high-order 4 bits is indeterminate, the read-modify-write instruction cannot be used.

• I²Ci transmit buffer register (IICiS0S)

Since the value of all bits is indeterminate, the read-modify-write instruction cannot be used.

■ **START condition generating procedure using multi-master**

```

:
FCLR      I                      (Interrupt disabled)
BTST     5, IICiS1              (BB flag confirming and branch process)
JC       BUSBUSY
BUSFREE:
MOV.B    SA, IICiS0             (Writing of slave address value <SA>)
NOP
NOP
MOV.B    #F0H, IICiS1          (Trigger of START condition generating)
FSET     I                      (Interrupt enabled)
:
BUSBUSY:
FSETI    (Interrupt enabled)
:

```

① Be sure to add NOP instruction X 2 between writing the slave address value and setting trigger of START condition generating shown the above procedure example.

② When using multi-master system, disable interrupts during the following three process steps:

- BB flag confirming
- Writing of slave address value
- Trigger of START condition generating

When the condition of the BB flag is bus busy, enable interrupts immediately.

When using single-master system, it is not necessary to disable interrupts above.

■ **RESTART condition generating procedure**

```

:
MOV.B    SA, IICiS0S           (Writing of slave address value <SA>) ——— ①
NOP
NOP
MOV.B    #F0H, IICiS1          (Trigger of RESTART condition generating)
:

```

① Use the I²Ci transmit buffer register to write the slave address value to the I²Ci data shift register. And also, be sure to add NOP instruction X 2.

■ **Writing to I²Ci status register**

Do not execute an instruction to set the PIN bit to “1” from “0” and an instruction to set the MST and TRX bits to “0” from “1” simultaneously. It is because it may enter the state that the SCL pin is released and the SDA pin is released after about one machine cycle. Do not execute an instruction to set the MST and TRX bits to “0” from “1” simultaneously when the PIN bit is “1.” It is because it may become the same as above.

■ **Process of after STOP condition generating**

Do not write data in the I²Ci data shift register (IICiS0) and the I²Ci status register (IICiS1) until the bus busy flag BB becomes “0” after generating the STOP condition in the master mode. It is because the STOP condition waveform might not be normally generated. Reading to the above registers do not have the problem.

M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.12 A-D Converter

The A-D converter consists of one 8-bit successive approximation A-D converter circuit with a capacitive coupling amplifier. Pins P36, P37, P40–P43 also function as the analog signal input pins. The direction registers of these pins for A-D conversion must therefore be set to input. The Vref connect bit (bit 5 at address 03D716) can be used to isolate the resistance ladder of the A-D converter from the reference voltage (VREF) when the A-D converter is not used. Doing so stops any current flowing into the resistance ladder from VREF, reducing the power dissipation. When using the A-D converter, start A-D conversion only after setting bit 5 of 03D716 to connect VREF.

The result of A-D conversion is stored in the A-D registers of the selected pins.

Table 2.12.1 shows the performance of the A-D converter. Figure 2.12.1 shows the block diagram of the A-D converter, and Figures 2.12.2 to 2.12.5 show the A-D converter-related registers.

Table 2.12.1 Performance of A-D converter

| Item | Performance |
|--------------------------------------|---|
| Method of A-D conversion | Successive approximation (capacitive coupling amplifier) |
| Analog input voltage (Note 1) | 0V to AVCC (VCC) |
| Operating clock ϕ_{AD} (Note 2) | $f_{AD}/\text{divide-by-2}$ of $f_{AD}/\text{divide-by-4}$ of f_{AD} , $f_{AD}=f(XIN)$ |
| Resolution | 8-bit |
| Absolute precision | VCC = 5V <ul style="list-style-type: none"> • Without sample and hold function: ± 5 LSB • With sample and hold function: ± 5 LSB |
| Operating modes | One-shot mode, repeat mode, single sweep mode, repeat sweep mode 0, and repeat sweep mode 1 |
| Analog input pins | 6 pins (AN0 to AN5) |
| A-D conversion start condition | <ul style="list-style-type: none"> • Software trigger A-D conversion starts when the A-D conversion start flag changes to "1" |
| Conversion speed per pin | <ul style="list-style-type: none"> • Without sample and hold function 49 ϕ_{AD} cycles • With sample and hold function 28 ϕ_{AD} cycles |

Notes 1: Does not depend on use of sample and hold function.

2: Divide the frequency if $f(XIN)$ exceeds 10 MHz, and make ϕ_{AD} frequency equal to 10 MHz. Without sample and hold function, set the ϕ_{AD} frequency to 250kHz min.

With the sample and hold function, set the ϕ_{AD} frequency to 1MHz min.

2.12.6 Sample and Hold

Sample and hold is selected by setting bit 0 of the A-D control register 2 (address 03D416) to "1". When sample and hold is selected, the rate of conversion of each pin increases. As a result, a 28 ϕ_{AD} cycle is achieved. Sample and hold can be selected in all modes. However, in all modes, be sure to specify before starting A-D conversion whether sample and hold is to be used.

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.13 D-A Converter

This is an 8-bit, R-2R type D-A converter. The microcomputer contains two independent D-A converters of this type.

D-A conversion is performed when a value is written to the corresponding D-A register. Bits 0 and 1 (D-A output enable bits) of the D-A control register decide if the result of conversion is to be output. Do not set the target port to output mode if D-A conversion is to be performed.

Output analog voltage (V) is determined by a set value (n : decimal) in the D-A register.

$$V = V_{REF} \times n / 256 \quad (n = 0 \text{ to } 255)$$

V_{REF} : reference voltage

Table 2.13.1 lists the performance of the D-A converter. Figure 2.13.1 shows the block diagram of the D-A converter. Figure 2.13.2 shows the A-D control register, Figure 2.13.3 shows the D-A register and Figure 2.13.4 shows the D-A converter equivalent circuit.

2.14 Data Slicer

This microcomputer includes the data slicer function for the closed caption decoder (referred to as the CCD). This function takes out the caption data superimposed in the vertical blanking interval of a composite video signal. A composite video signal which makes the sync chip's polarity negative is input to the CVIN pin.

When the data slicer function is not used, the data slicer circuit and the timing signal generating circuit can be cut off by setting bit 0 of the data slicer control register 1 (address 0260₁₆) to "0." These settings can realize the low-power dissipation.

Note: When using the data slicer, set bit 7 of the peripheral mode register (address 027D₁₆) according to the main clock frequency.

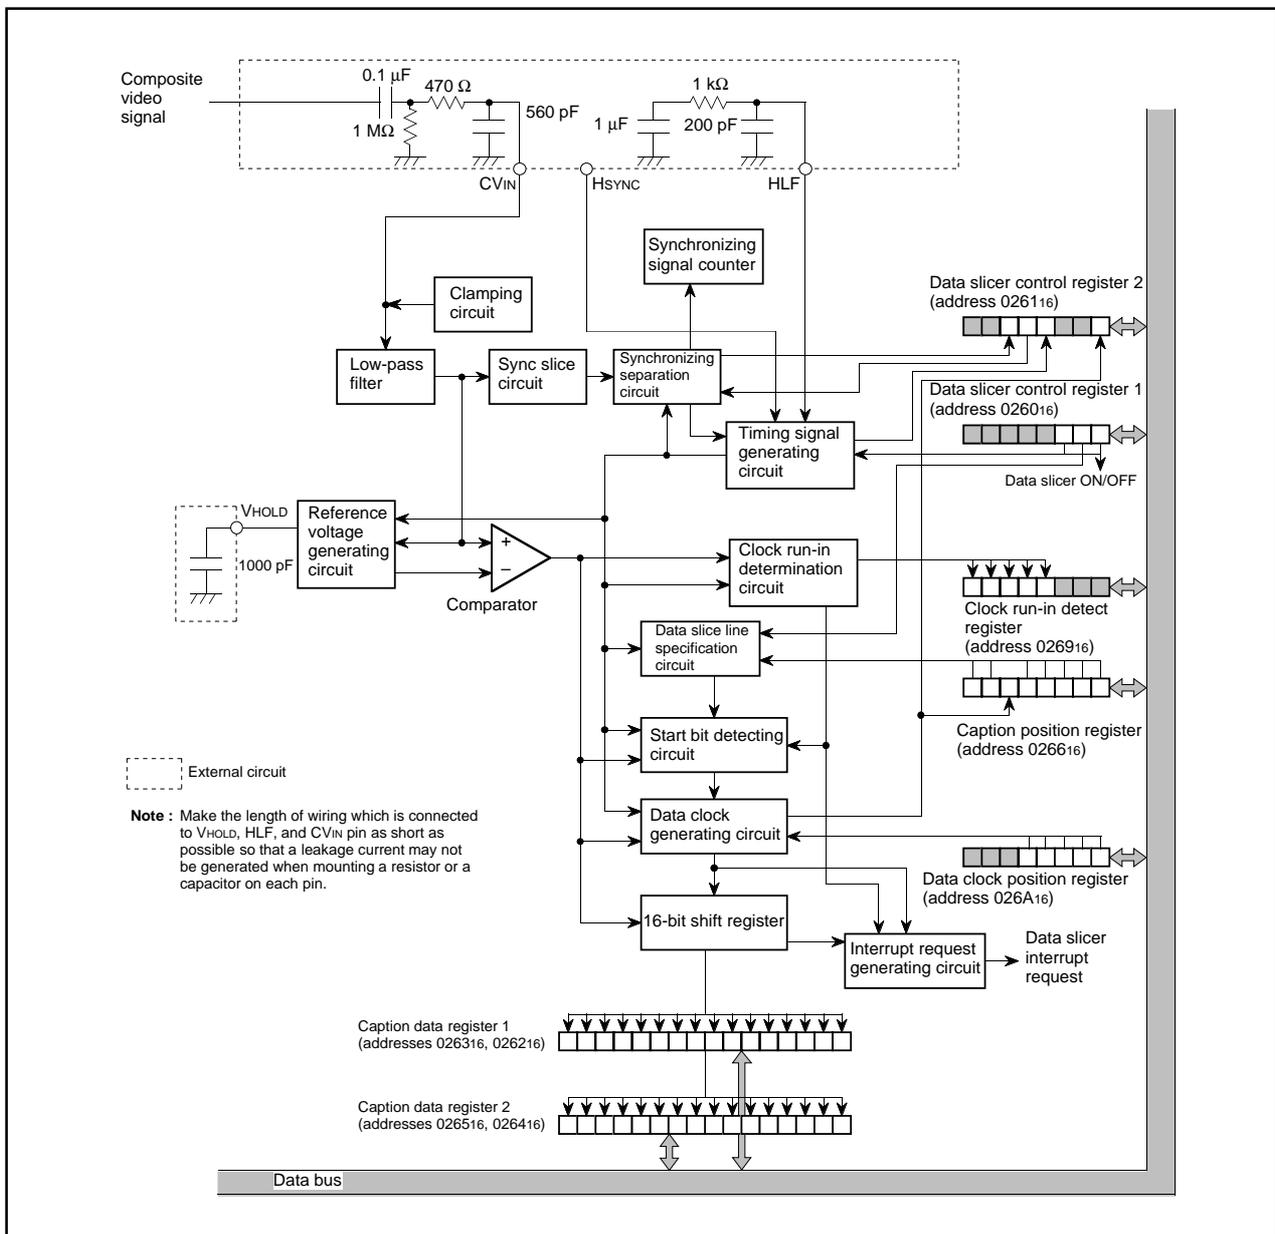

Figure 2.14.1 Data slicer block diagram

2.14.1 Notes when not Using Data Slicer

When bit 0 of data slicer control register 1 (address 026016) is "0," terminate the pins as shown in Figure 2.14.2

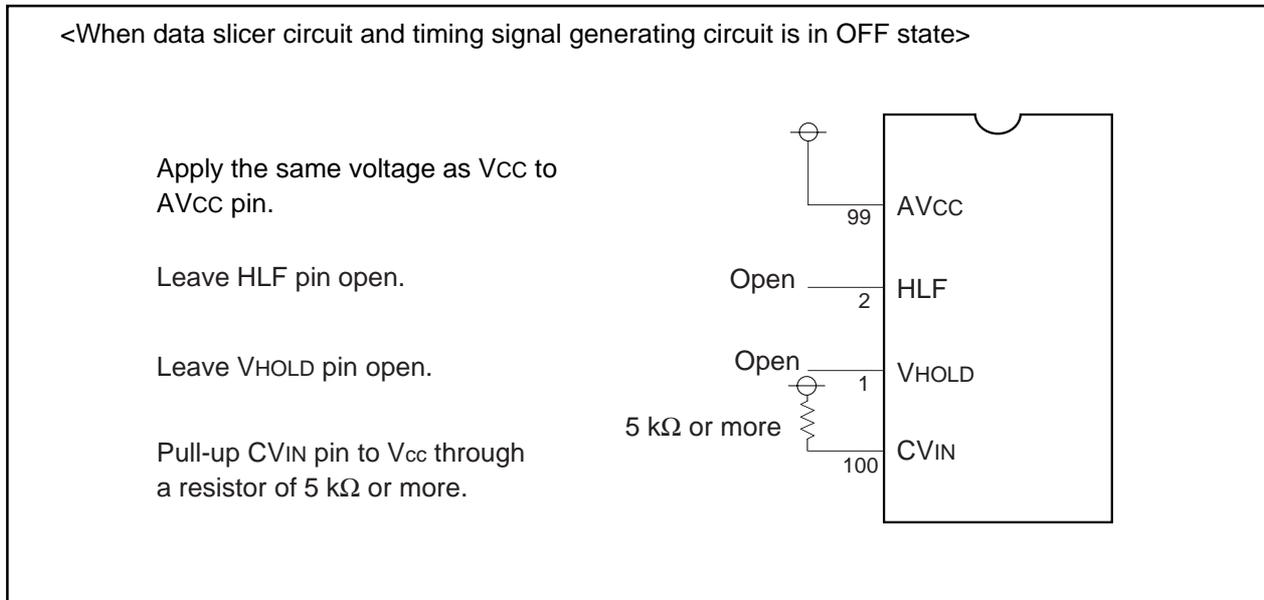

Figure 2.14.2 Termination of data slicer input/output pins when data slicer circuit and timing generating circuit is in OFF state

When both bits 0 and 2 of data slicer control register 1 (address 026016) are "1," terminate the pins as shown in Figure 2.14.3.

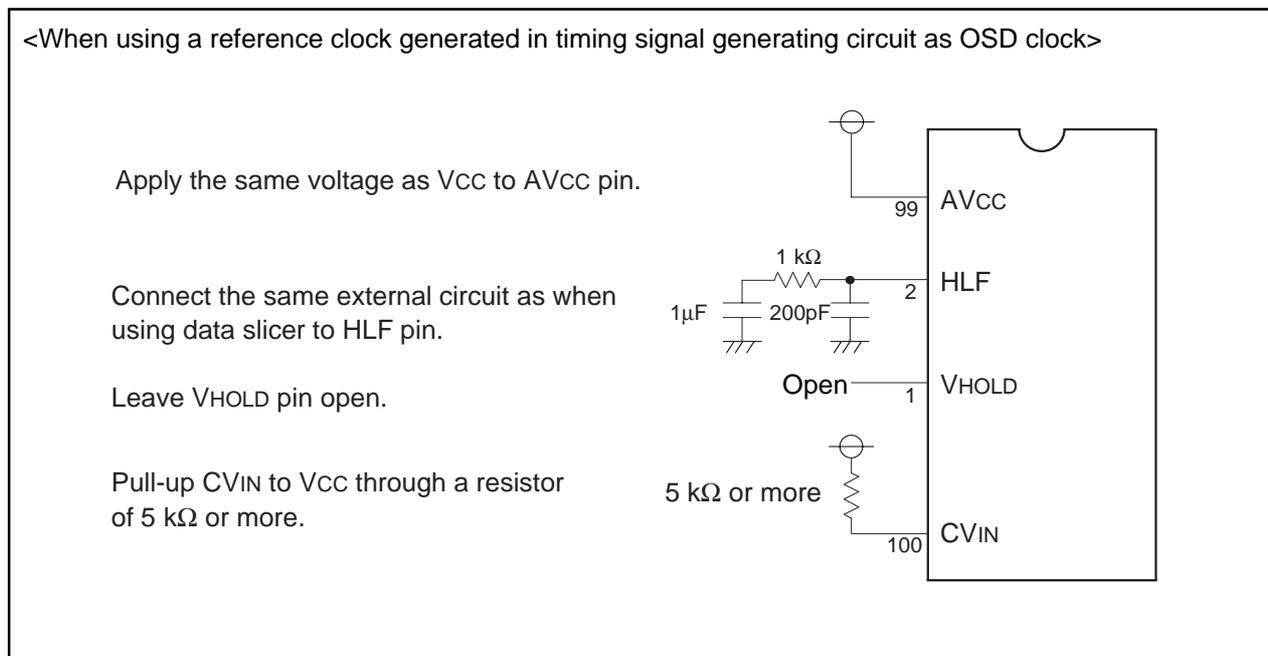

Figure 2.14.3 Termination of data slicer input/output pins when timing signal generating circuit is in ON state

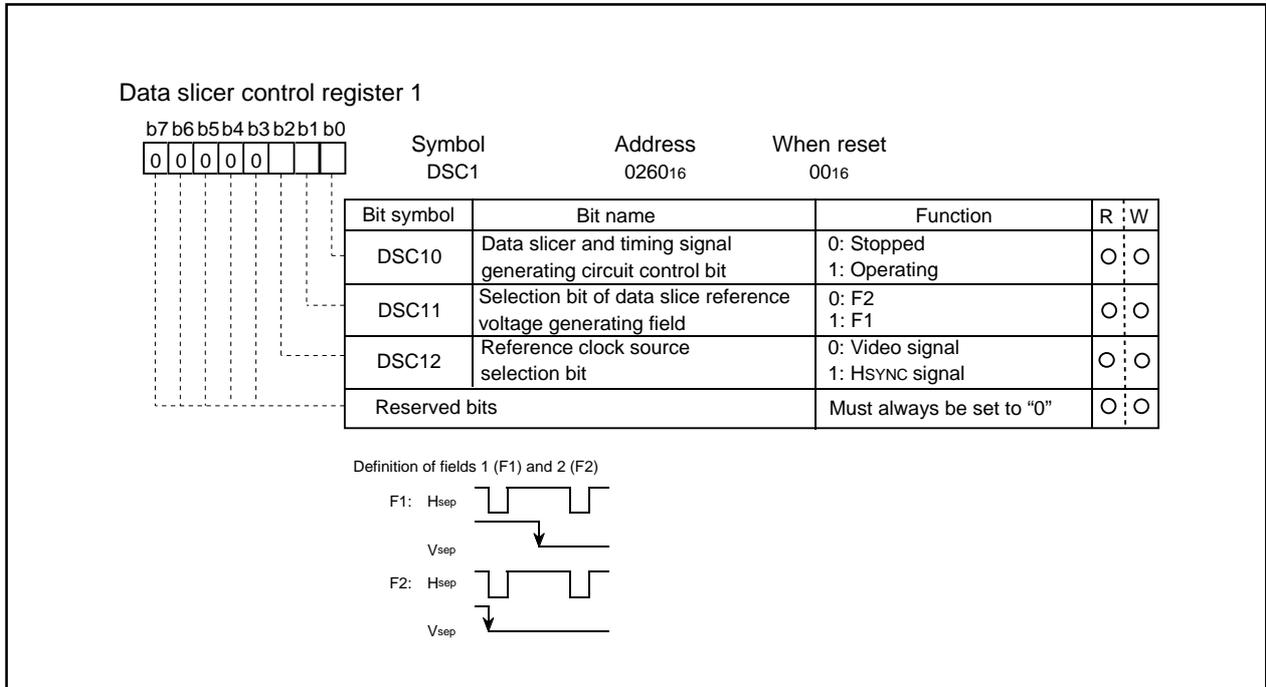

Figure 2.14.4 Data slicer control register 1

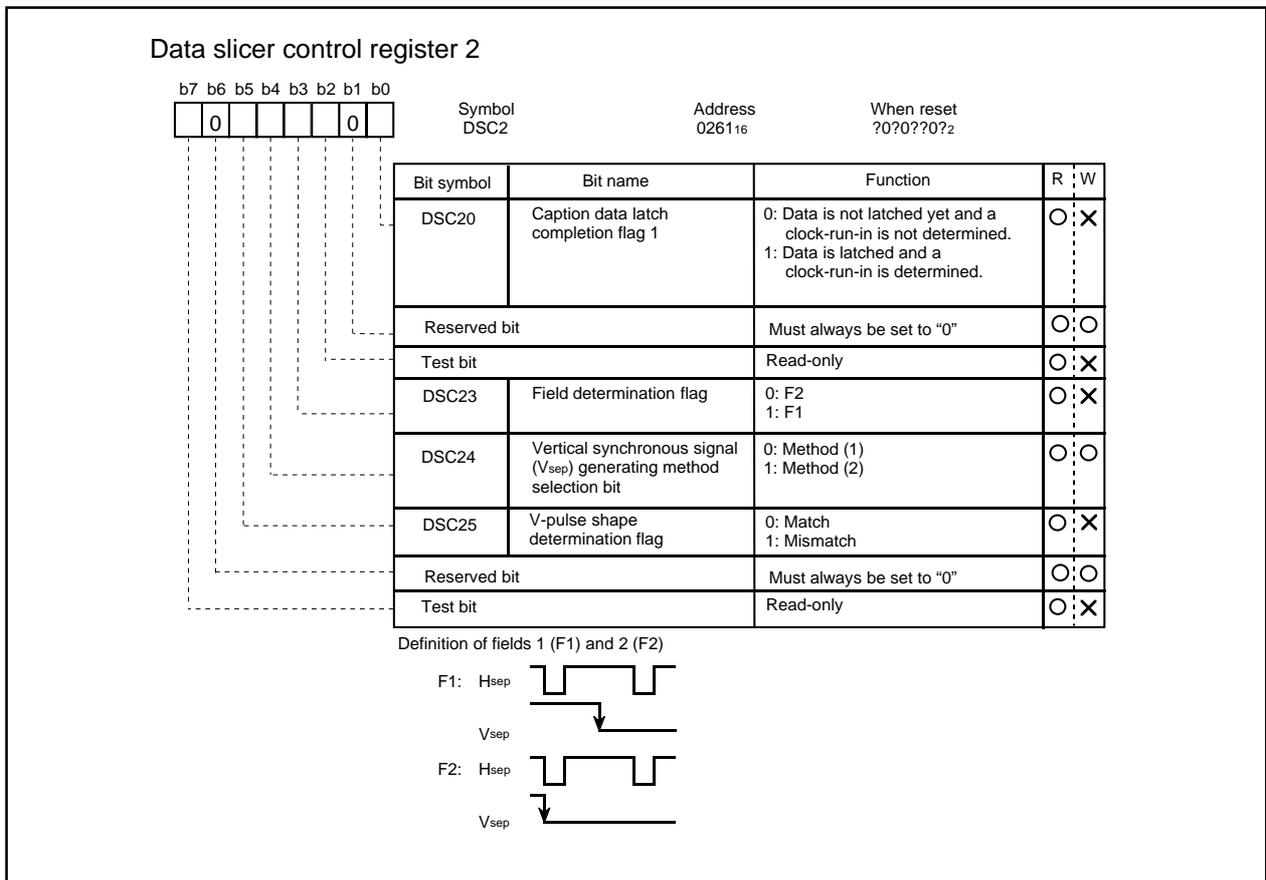

Figure 2.14.5 Data slicer control register 2

2.14.2 Clamping Circuit and Low-pass Filter

The clamp circuit clamps the sync chip part of the composite video signal input from the CVIN pin. The low-pass filter attenuates the noise of clamped composite video signal. The CVIN pin to which composite video signal is input requires a capacitor (0.1 mF) coupling outside. Pull down the CVIN pin with a resistor of hundreds of kilohms to 1 M Ω . In addition, we recommend to install externally a simple low-pass filter using a resistor and a capacitor at the CVIN pin (refer to Figure 2.14.1).

2.14.3 Sync Slice Circuit

This circuit takes out a composite sync signal from the output signal of the low-pass filter.

2.14.4 Synchronous Signal Separation Circuit

This circuit separates a horizontal synchronous signal and a vertical synchronous signal from the composite sync signal taken out in the sync slice circuit.

(1) Horizontal synchronous signal (Hsep)

A one-shot horizontal synchronizing signal Hsep is generated at the falling edge of the composite sync signal.

(2) Vertical synchronous signal (Vsep)

As a Vsep signal generating method, it is possible to select one of the following 2 methods by using bit 4 of the data slicer control register 2 (address 026116).

- Method 1 The "L" level width of the composite sync signal is measured. If this width exceeds a certain time, a Vsep signal is generated in synchronization with the rising of the timing signal immediately after this "L" level.
- Method 2 The "L" level width of the composite sync signal is measured. If this width exceeds a certain time, it is detected whether a falling of the composite sync signal exits or not in the "L" level period of the timing signal immediately after this "L" level. If a falling exists, a Vsep signal is generated in synchronization with the rising of the timing signal (refer to Figure 2.14.6).

Figure 2.14.6 shows a Vsep generating timing. The timing signal shown in the figure is generated from the reference clock which the timing generating circuit outputs.

Reading bit 5 of data slicer control register 2 permits determining the shape of the V-pulse portion of the composite sync signal. As shown in Figure 2.14.7, when the A level matches the B level, this bit is "0." In the case of a mismatch, the bit is "1."

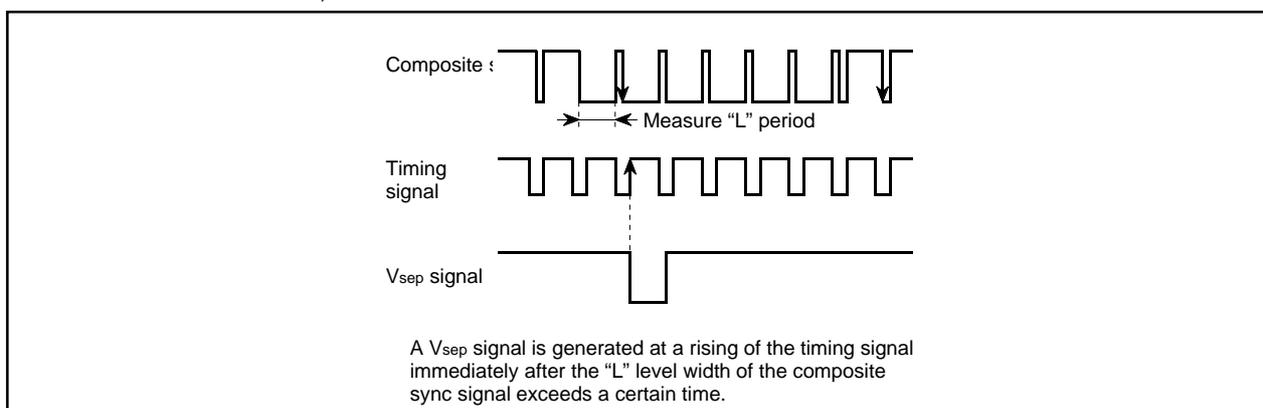

Figure 2.14.6 Vsep generating timing (method 2)

2.14.5 Timing Signal Generating Circuit

This circuit generates a reference clock which is 832 times as large as the horizontal synchronous signal frequency. It also generates various timing signals on the basis of the reference clock, horizontal synchronous signal and vertical synchronizing signal. The circuit operates by setting bit 0 of data slicer control register 1 (address 0260₁₆) to "1."

The reference clock can be used as a display clock for OSD function in addition to the data slicer. The HSYNC signal can be used as a count source instead of the composite sync signal. However, when the HSYNC signal is selected, the data slicer cannot be used. A count source of the reference clock can be selected by bit 2 of data slicer control register 1 (address 0260₁₆).

For the pins HLF, connect a resistor and a capacitor as shown in Figure 2.14.1 Make the length of wiring which is connected to these pins as short as possible so that a leakage current may not be generated.

Note: It takes a few tens of milliseconds until the reference clock becomes stable after the data slicer and the timing signal generating circuit are started. In this period, various timing signals, Hsep signals and Vsep signals become unstable. For this reason, take stabilization time into consideration when programming.

CPS is caption position register.
2: Set "00₁₆" to "10₁₆" to bits 4 to 0 of CPS.
3: Set "00₁₆" to "1F₁₆" to bits 4 to 0 of CPS.

2.14.7 Reference Voltage Generating Circuit and Comparator

The composite video signal clamped by the clamping circuit is input to the reference voltage generating circuit and the comparator.

(1) Reference voltage generating circuit

This circuit generates a reference voltage (slice voltage) by using the amplitude of the clock run-in pulse in line specified by the data slice line specification circuit. Connect a capacitor between the VHOLD pin and the VSS pin, and make the length of wiring as short as possible so that a leakage current may not be generated.

(2) Comparator

The comparator compares the voltage of the composite video signal with the voltage (reference voltage) generated in the reference voltage generating circuit, and converts the composite video signal into a digital value.

2.14.8 Start Bit Detecting Circuit

This circuit detects a start bit at line decided in the data slice line specification circuit.

The detection of a start bit is described below.

- ① A sampling clock is generated by dividing the reference clock output by the timing signal.
- ② A clock run-in pulse is detected by the sampling clock.
- ③ After detection of the pulse, a start bit pattern is detected from the comparator output.

2.14.9 Clock Run-in Determination Circuit

This circuit determinates clock run-in by counting the number of pulses in a window of the composite video signal.

The reference clock count value in one pulse cycle is stored in bits 3 to 7 of the clock run-in detect register (address 0269₁₆). Read out these bits after the occurrence of a data slicer interrupt (refer to 2.14.12 Interrupt request generating circuit).

Figure 2.14.10 shows the structure of clock run-in detect register.

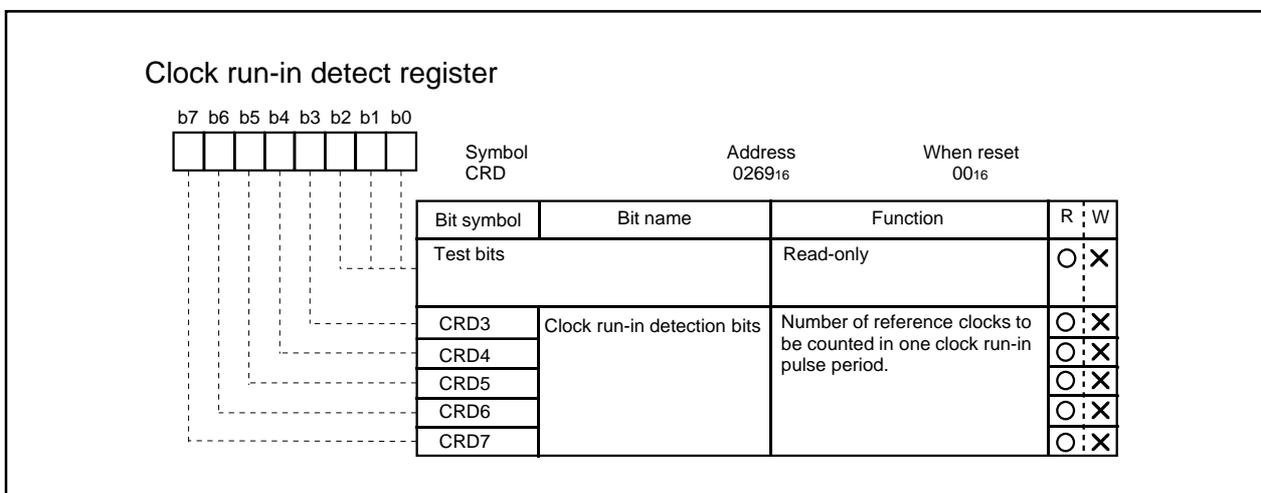

Figure 2.14.10 Clock run-in detect register

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.14.10 Data Clock Generating Circuit

This circuit generates a data clock synchronized with the start bit detected in the start bit detecting circuit. The data clock stores caption data to the 16-bit shift register. When the 16-bit data has been stored and the clock run-in determination circuit determines clock run-in, the caption data latch completion flag is set. This flag is reset at a falling of the vertical synchronous signal (V_{sep}).

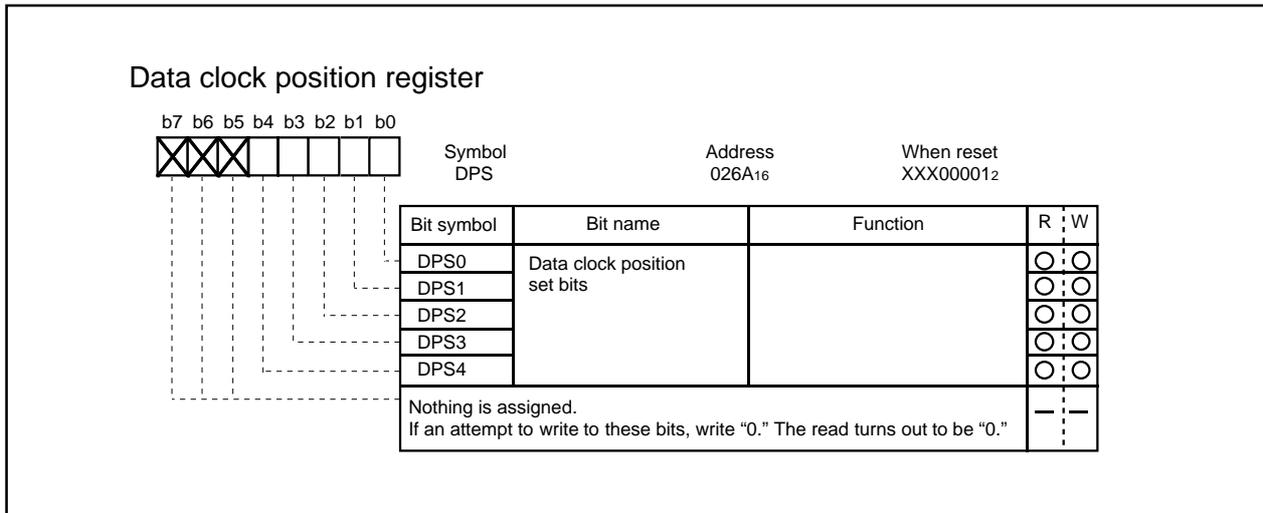

Figure 2.14.11 Data clock position register

2.14.11 16-bit Shift Register

The caption data converted into a digital value by the comparator is stored into the 16-bit shift register in synchronization with the data clock. The contents of the stored caption data can be obtained by reading out the caption data register 1 (addresses 0263₁₆, 0262₁₆) and caption data register 2 (addresses 0265₁₆, 0264₁₆). These registers are reset to "0" at a falling of V_{sep} . Read out data registers 1 and 2 after the occurrence of a data slicer interrupt (refer to "2.14.12 Interrupt request generating circuit").

and ON-SCREEN DISPLAY CONTROLLER

2.14.12 Interrupt Request Generating Circuit

The interrupt requests as shown in Table 2.14.3 are generated by combination of the following bits; bits 6 and 7 of the caption position register (address 0266₁₆). Read out the contents of data registers 1, 2 and the contents of bits 3 to 7 of the clock run-in detect register after the occurrence of a data slicer interrupt request.

Table 2.14.2 Contents of caption data latch completion flag and 16-bit shift register

| Slice Line Specification Mode | | Contents of Caption Data Latch Completion Flag | | Contents of 16-bit Shift Register | |
|-------------------------------|-------|--|--|---|---|
| CPS | | Completion Flag 1 (bit 0 of DSC2) | Completion Flag 2 (bit 5 of CPS) | Caption Data Register 1 | Caption Data Register 2 |

2.15 HSYNC Counter

The synchronous signal counter counts HSYNC from HSYNC count input pins (HC0/P75, HC1/P77) as a count source.

The count value in a certain time (T time; 1024 μ s, 2048 μ s, 4096 μ s and 8192 μ s) divided system clock f32 is stored into the 8-bit latch.

Accordingly, the latch value changes in the cycle of T time. When the count value exceeds "FF16," "FF16" is stored into the latch.

The latch value can be obtained by reading out the HSYNC counter latch (address 027F16). A count source and count update cycle (T time) are selected by bits 0, 3 and 4 of the HSYNC counter register.

Figure 2.15.1 shows the HSYNC counter and Figure 2.15.2 shows the synchronous signal counter block diagram.

Note: When using the HSYNC counter, set the port direction register corresponding to the HSYNC count input pins for input.

2.16 OSD Functions

Table 2.16.1 outlines the OSD functions of this microcomputer. This OSD function can display the following: the block display (32 characters X 16 lines or 42 characters X 16 lines) and the SPRITE display, and can display the both display at the same time. There are 3 display modes and they are selected by a block unit. The display modes are selected by block control register i (i = 1 to 16). The features of each display are described below.

Note: When using OSD function, select “No-division mode” as BCLK operating mode and set the main clock frequency to $f(XIN) = 10 \text{ MHz}$.

Table 2.16.1 Features of each display style

| Display style Parameter | | Block display | | | | SPRITE display | |
|---------------------------------------|-------------------|---|---|---|---|--|--|
| | | CC mode (Closed caption mode) | OSD mode (On-screen display mode) | | | | CDOSD mode (Color dot on-screen display mode) |
| | | | OSDS mode | OSDP mode | OSDL mode | | |
| Number of display characters | | 32 characters X 16 lines/42 characters X 16 lines | | | | 1 character X 2 lines | |

2.16.1 Triple Layer OSD

Three built-in layers of display screens accommodate triple display of channels, volume, etc., closed caption, and sprite displays within layers 1 to 3.

The layer to be displayed in each block is selected by bit 0 or 1 of the OSD control register 2 for each display mode (refer to Figure 2.16.7). Layer 3 always displays the sprite display.

When the layer 1 block and the layer 2 block overlay, the screen is composed with layer mixing by bit 6 or 7 of the OSD control register 1, as shown in Figure 2.16.5. Layer 3 always takes display priority of layers 1 and 2.

Notes 1: When mixing layer 1 and layer 2, note Table 2.16.2.

2: OSDP mode is always displayed on layer 1. And also, it cannot be overlapped with layer 2's block.

3: OUT2 is always ORed, regardless of values of bits 6, 7 of the OSD control register 1. And besides, even when OUT2 (layer 1 and layer 2) overlaps with SPRITE display (layer 3), OUT2 is output without masking.

Table 2.16.2 Mixing layer 1 and layer 2

| Parameter \ Block | Block in Layer 1 | Block in Layer 2 | |
|-----------------------------------|---|--|---|
| Display mode | CC, OSDS/L, CDOSD mode | OSDS/L, CDOSD mode | |
| Pre-divide ratio | X 1, X 2 (CC mode) X 1 to X 3 (OSD, CDOSD mode) | Same as layer 1 (See note) | |
| Dot size | 1Tc X 1/2H, 1Tc X 1H (CC mode) | Pre-divide ratio = X 1 | Pre-divide ratio = X 2 |
| | | 1Tc X 1/2H 1Tc X 1H | 1TcX1/2H, 1.5TcX1/2H 1TcX1H, 1.5TcX1H(Seenote) |
| | 1Tc X 1H, 1Tc X 1/2H, 2Tc X 2H, 3Tc X 3H (OSDS/L, CDOSD mode) | <ul style="list-style-type: none"> • Same size as layer 1 • 1.5Tc can be selected only when: layer 1's pre-divide ratio = X 2 AND layer 1's horizontal dot size = 1Tc. As this time, vertical dot size is the same as layer 1. | |
| Horizontal display start position | Arbitrary | Same position as layer 1 | |
| Vertical display start position | Arbitrary However, when dot size is 2Tc X 2H or 2Tc X 3H, set difference between vertical display position of layer 1 and that of layer 2 as follows. <ul style="list-style-type: none"> •2Tc X 2H: 2H units •3Tc X 3H: 3H units | | |

Note: In the OSDL mode, 1.5Tc size cannot be used.

and ON-SCREEN DISPLAY CONTROLLER

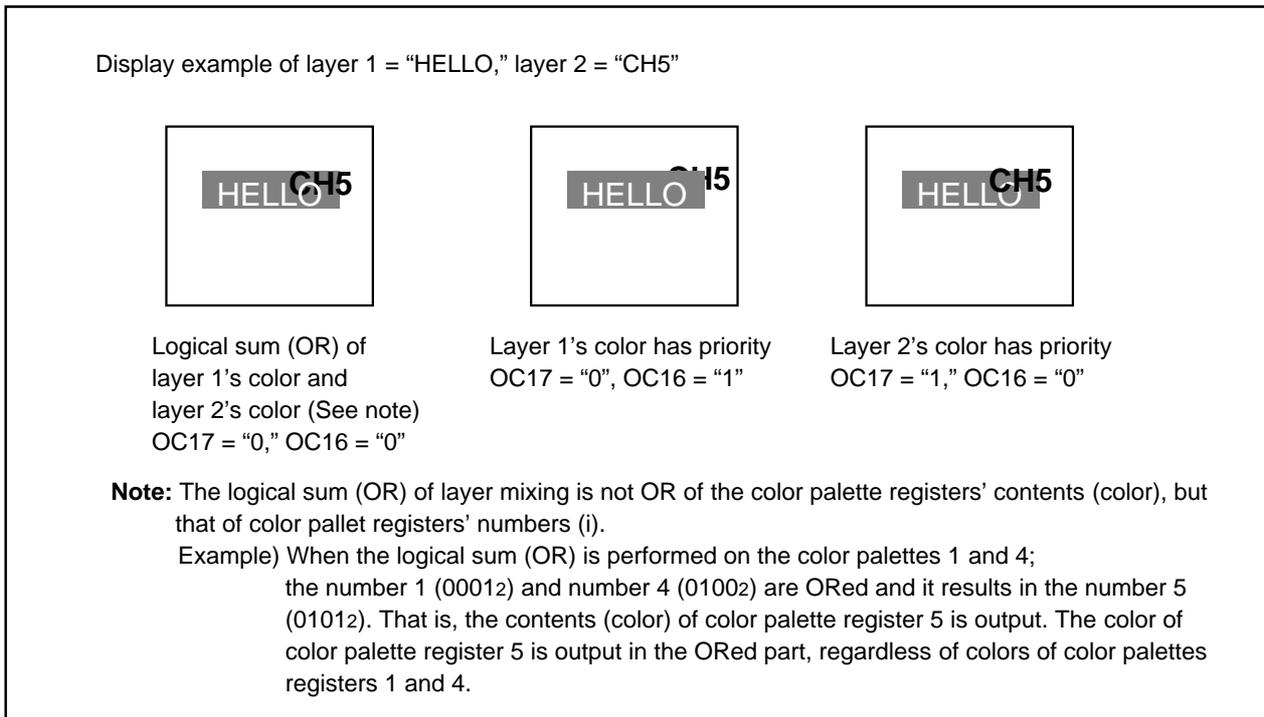

Figure 2.16.6 Display example of triple layer OSD

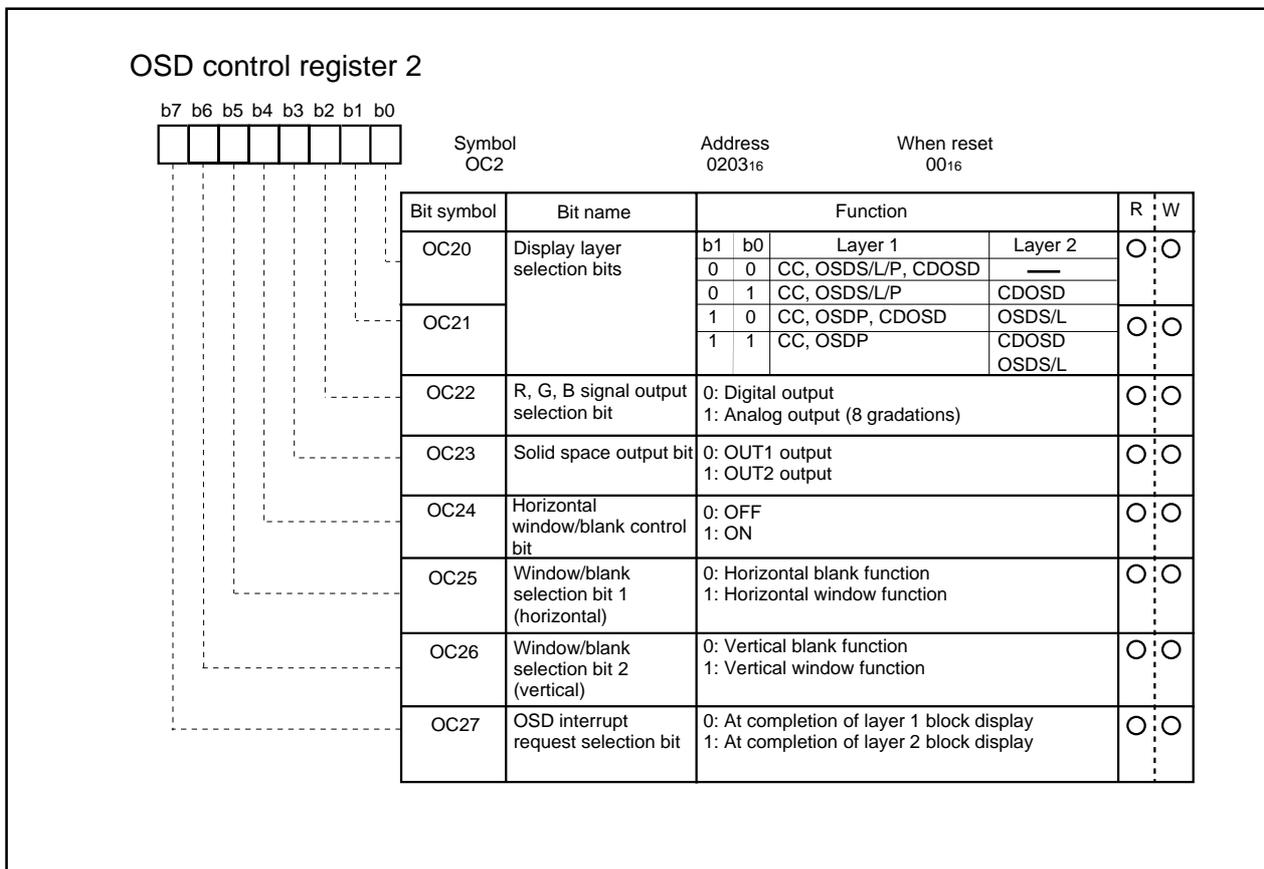

Figure 2.16.7 OSD control register 2

2.16.2 Display Position

The display positions of characters are specified by a block. There are 16 blocks, blocks 1 to 16. Up to 32 characters (32-character mode)/42 characters (42-character mode)/ can be displayed in each block (refer to 2.16.6 Memory for OSD).

The display position of each block can be set in both horizontal and vertical directions by software.

The display position in the horizontal direction can be selected for all blocks in common from 256-step display positions in units of 4 TOSC (TOSC = OSD oscillation cycle).

The display position in the vertical direction for each block can be selected from 1024-step display positions in units of 1 TH (TH = HSYNC cycle).

Blocks are displayed in conformance with the following rules:

- When the display position is overlapped with another block in the same layer (Figure 2.16.8 (b)), a lower block number (1 to 16) is displayed on the front.
- When another block display position appears while one block is displayed in the same layer (Figure 2.16.8 (c)), the block with a larger set value as the vertical display start position is displayed. However, do not display block with the dot size of 2Tc X 2H or 3Tc X 3H during display period (*) of another block.
 - * In the case of OSDSP mode block: 20 dots in vertical from the vertical display start position.
 - * In the case of OSDL mode block: 32 dots in vertical from the vertical display start position.
 - * In the case of CC or CDOSD mode block: 26 dots in vertical from the vertical display start position.

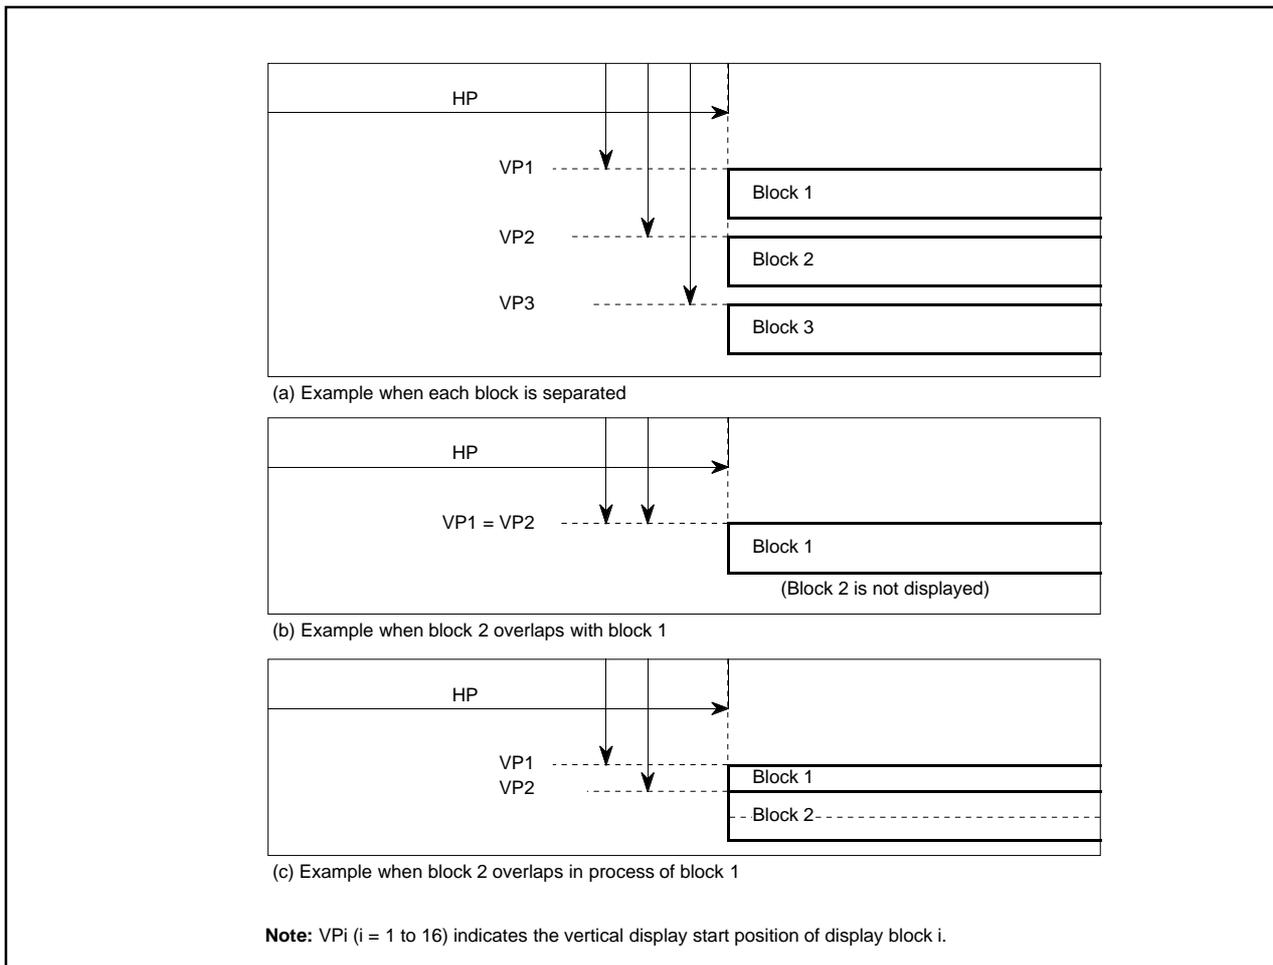

Figure 2.16.8 Display position

The display position in the vertical direction is determined by counting the horizontal sync signal (HSYNC). At this time, when VSYNC and HSYNC are positive polarity (negative polarity), it starts to count the rising edge (falling edge) of HSYNC signal from after fixed cycle of rising edge (falling edge) of VSYNC signal. So interval from rising edge (falling edge) of VSYNC signal to rising edge (falling edge) of HSYNC signal needs enough time ($2 \times \text{BCLK}$ cycles or more) for avoiding jitter. The polarity of HSYNC and VSYNC signals can select with the I/O polarity control register (address 020616).

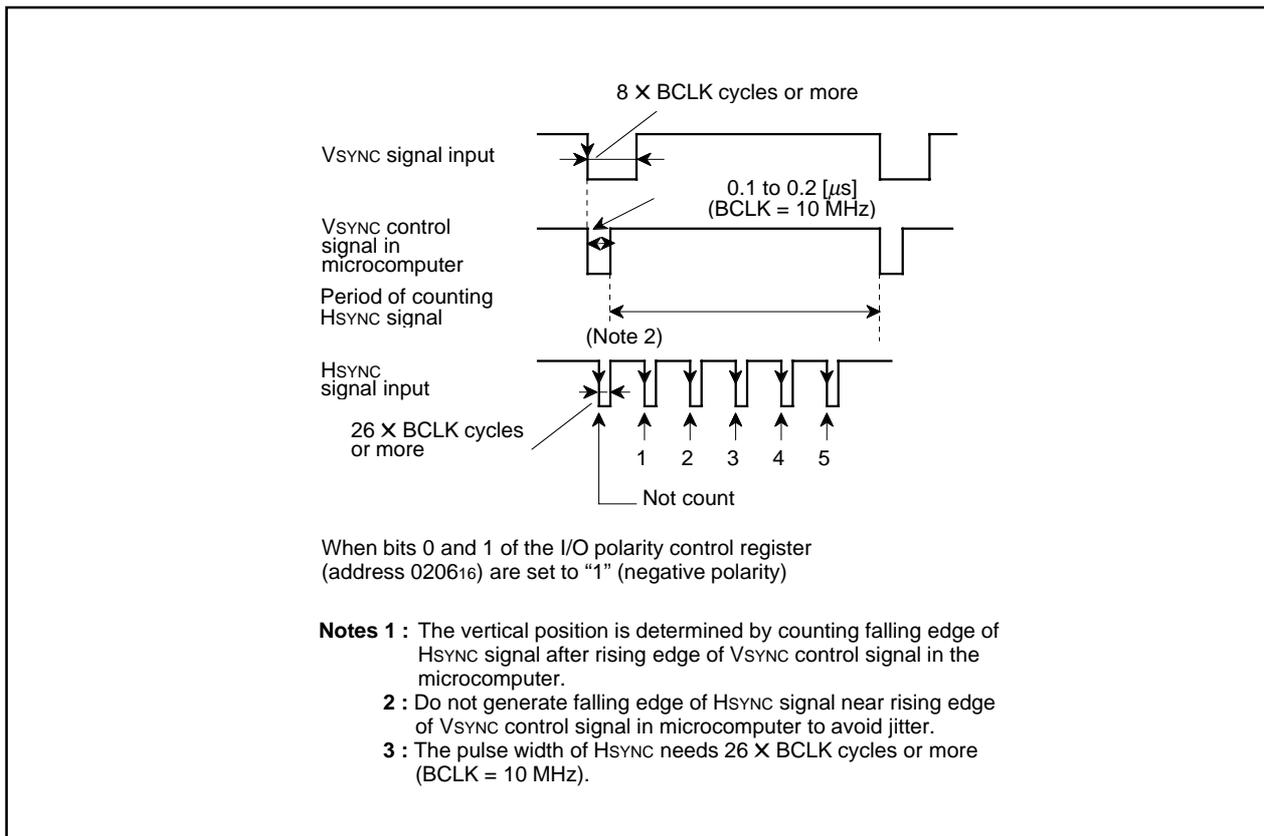

Figure 2.16.9 Supplement explanation for display position

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

The vertical position for each block can be set in 1024 steps (where each step is $1T_H$ (T_H : Hsync cycle)) as values "002₁₆" to "3FF₁₆" in vertical position register i ($i = 1$ to 16) (addresses 0220₁₆ to 023F₁₆). The vertical position register i is shown in Figure 2.16.10.

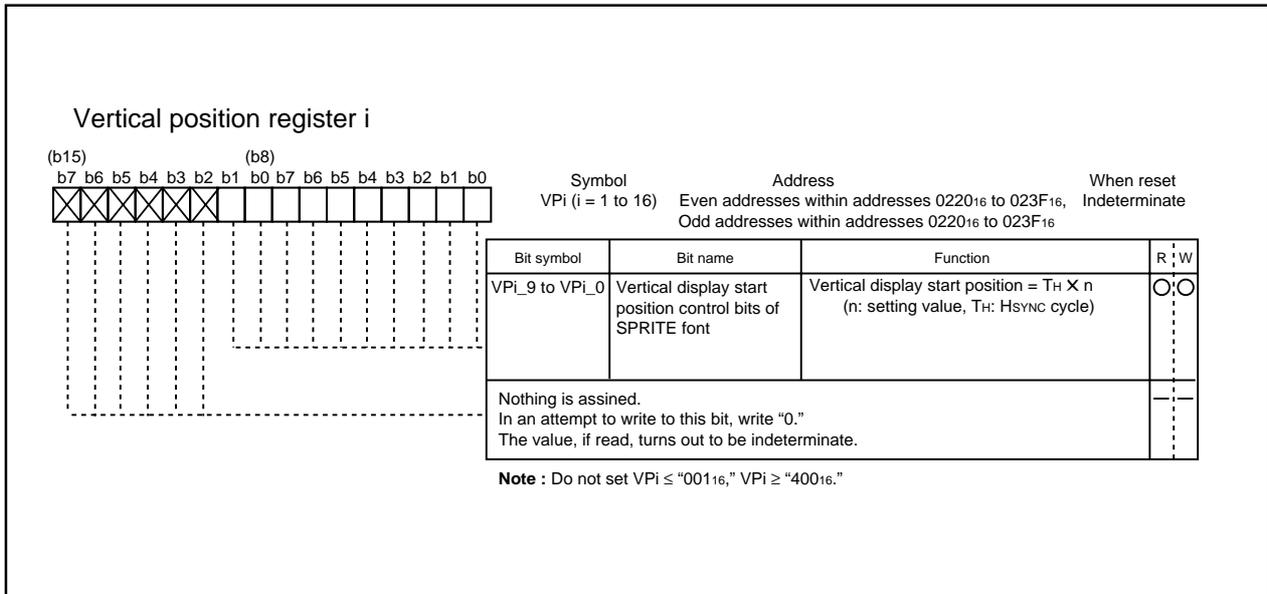

Figure 2.16.10 Vertical position register i ($i = 1$ to 16)

The horizontal position is common to all blocks, and can be set in 256 steps (where 1 step is $4T_{OSC}$, T_{OSC} being OSD oscillation cycle) as values "00₁₆" to "FF₁₆" in bits 0 to 7 of the horizontal position register (address 0204₁₆). The horizontal position register is shown in Figure 2.16.11.

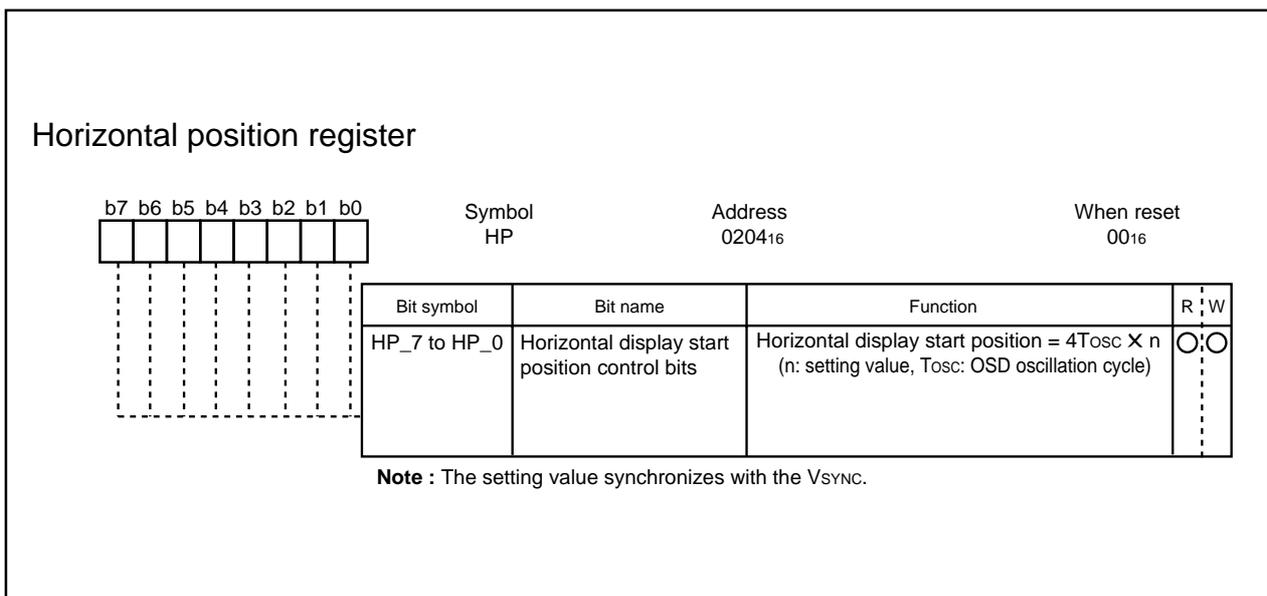

Figure 2.16.11 Horizontal position register

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

Note : $1T_c$ (T_c : OSD clock cycle divided in pre-divide circuit) gap occurs between the horizontal display start position set by the horizontal position register and the most left dot of the 1st block. Accordingly, when 2 blocks have different pre-divide ratios, their horizontal display start position will not match.

Ordinary, this gap is $1T_c$ regardless of character sizes, however, the gap is $1.5T_c$ only when the character size is $1.5T_c$.

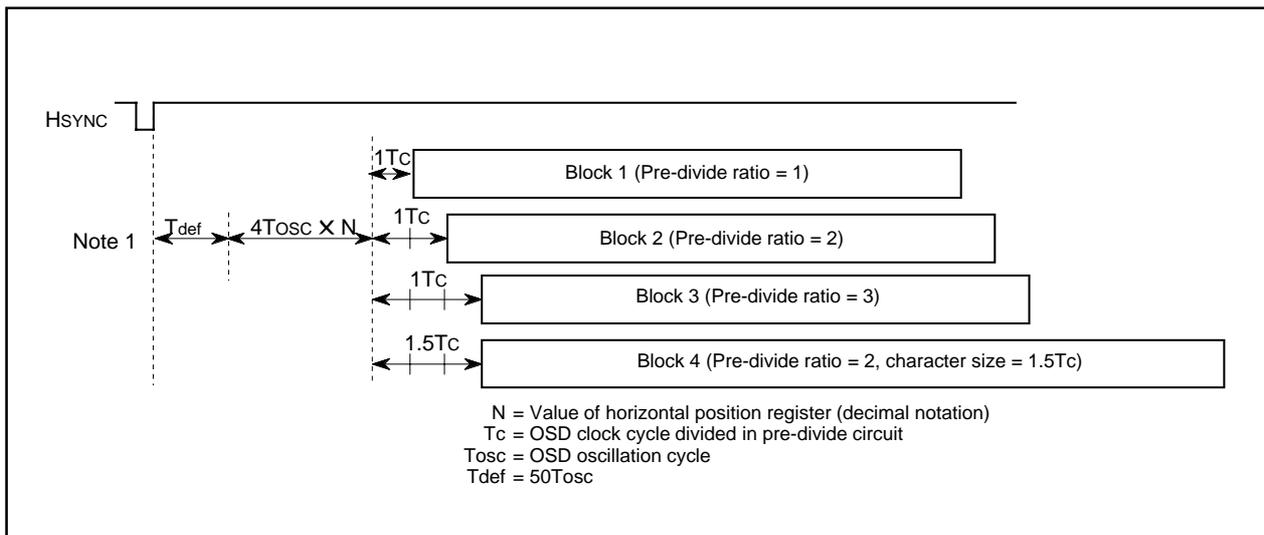

Figure 2.16.12 Notes on horizontal display start position

2.16.3 Dot Size

The dot size can be selected by a block unit. The dot size in vertical direction is determined by dividing HSYNC in the vertical dot size control circuit. The dot size in horizontal is determined by dividing the following clock in the horizontal dot size control circuit : the clock gained by dividing the OSD clock source (data slicer clock, OSC1, main clock) in the pre-divide circuit. The clock cycle divided in the pre-divide circuit is defined as 1Tc.

The dot size is specified by bits 3 to 6 of the block control register.

Refer to Figure 2.16.4 (the block control register i), refer to Figure 2.16.15 (the clock control register).

The block diagram of dot size control circuit is shown in Figure 2.16.13.

Notes 1 : The pre-divide ratio = 3 cannot be used in the CC mode.

2 : The pre-divide ratio of the layer 2 must be same as that of the layer 1 by the block control register i.

3 : In the bi-scan mode, the dot size in the vertical direction is 2 times as compared with the normal mode. Refer to “2.16.18 Scan Mode” about the scan mode.

and ON-SCREEN DISPLAY CONTROLLER

2.16.4 Clock for OSD

As a clock for display to be used for OSD, it is possible to select one of the following 3 types.

- Data slicer clock output from the data slicer (approximately 26 MHz)
- Clock from the LC oscillator supplied from the pins OSC1 and OSC2
- Clock from the ceramic resonator (or the quartz-crystal oscillator) from the pins OSC1 and OSC2

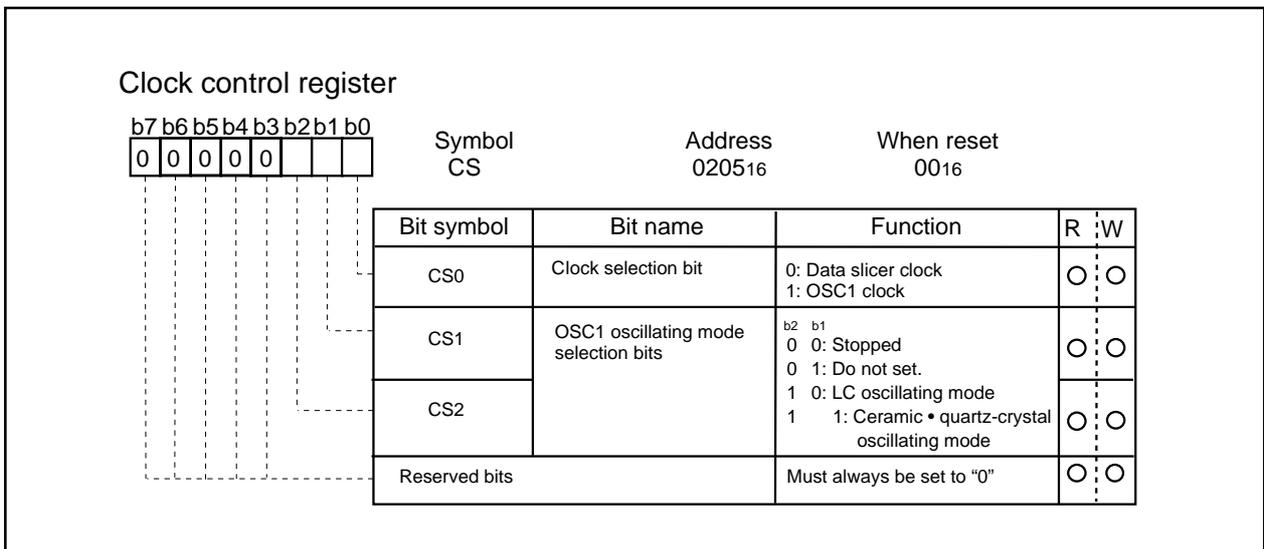

Figure 2.16.15 Clock control register

M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.16.5 Field Determination Display

To display the block with vertical dot size of 1/2H, whether an even field or an odd field is determined through differences in a synchronizing signal waveform of interlacing system. The dot line 0 or 1 (refer to Figure 2.16.18) corresponding to the field is displayed alternately.

In the following, the field determination standard for the case where both the horizontal sync signal and the vertical sync signal are negative-polarity inputs will be explained. A field determination is determined by detecting the time from a falling edge of the horizontal sync signal until a falling edge of the VSYNC control signal (refer to Figure 2.16.9) in the microcomputer and then comparing this time with the time of the previous field. When the time is longer than the comparing time, it is regarded as even field. When the time is shorter, it is regarded as odd field.

The field determination flag changes at a rising edge of VSYNC control signal in the microcomputer .

The contents of this field can be read out by the field determination flag (bit 7 of the I/O polarity control register at address 0206₁₆). A dot line is specified by bit 6 of the I/O polarity control register (refer to Figure 2.16.18).

However, the field determination flag read out from the CPU is fixed to "0" at even field or "1" at odd field, regardless of bit 6.

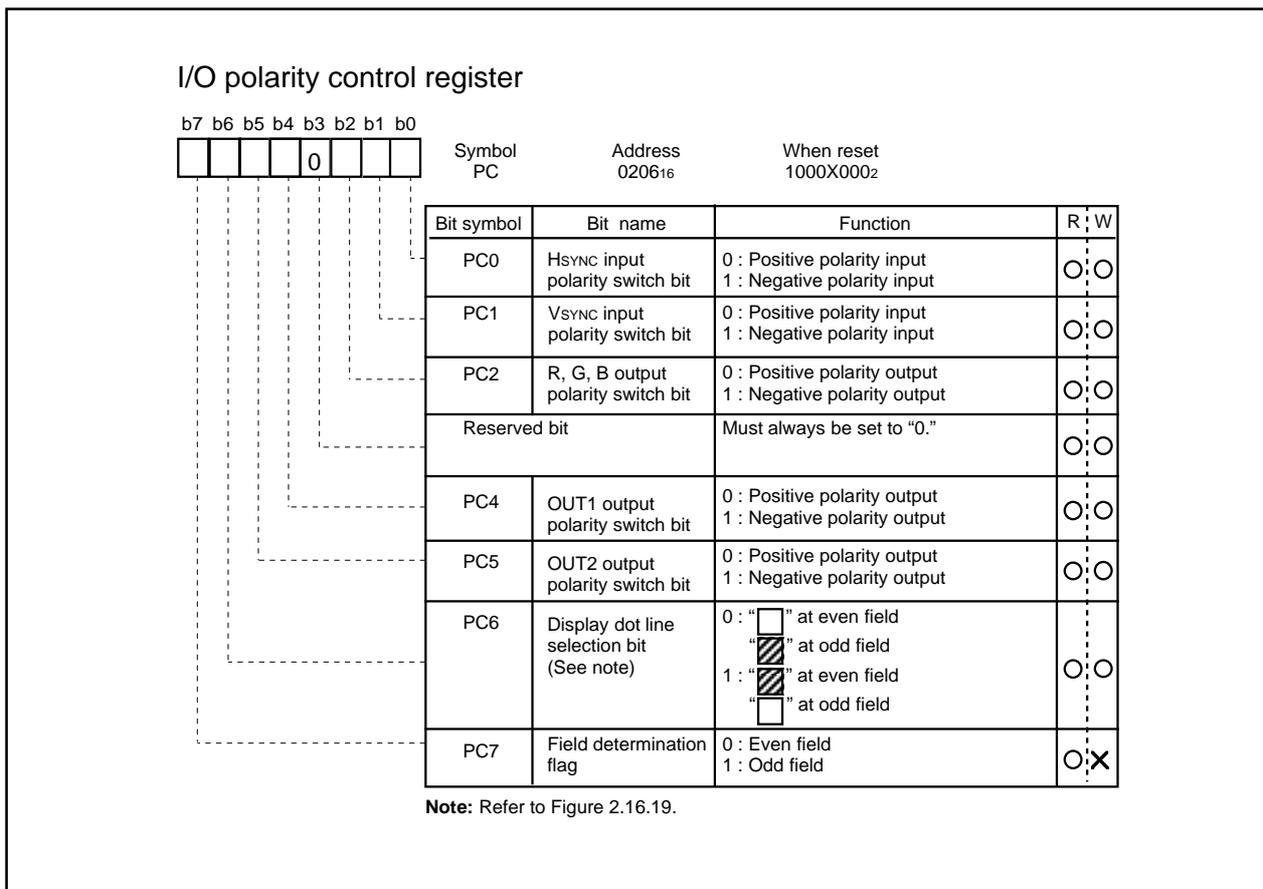

Figure 2.16.17 I/O polarity control register

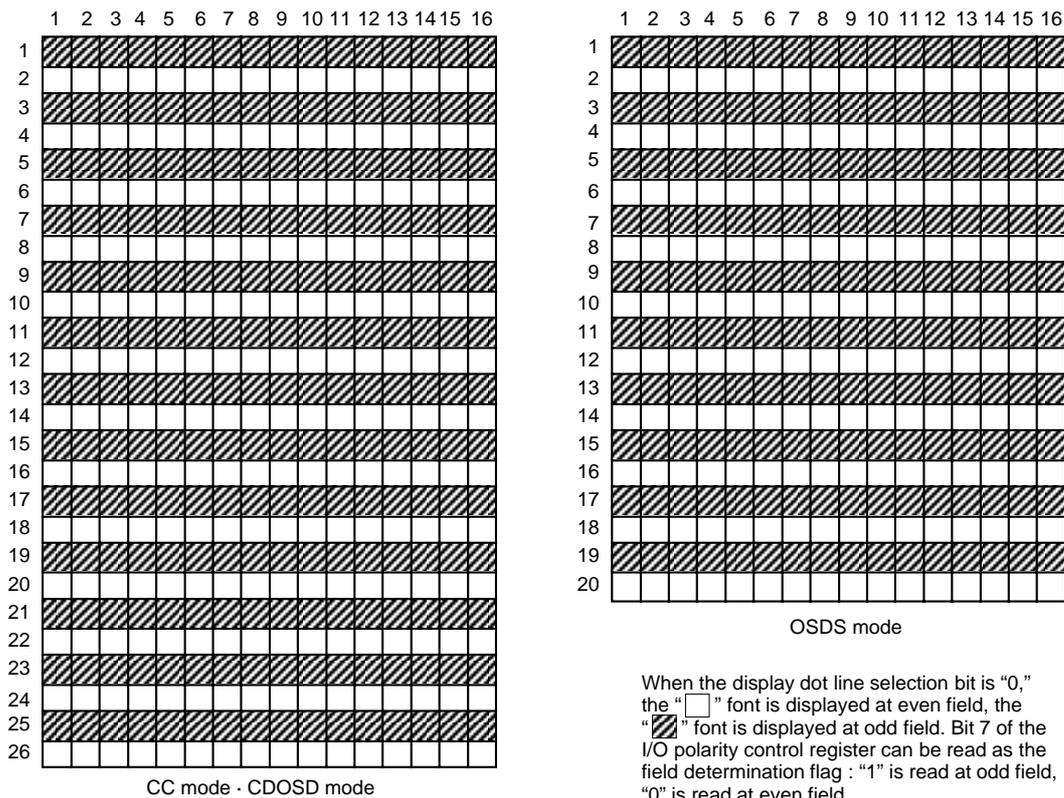

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

Both Hsync signal and Vsync signal are negative-polarity input

| Hsync | | Field | Field determination flag(Note) | Display dot line selection bit | Display dot line |
|--|--|-------|--------------------------------|--------------------------------|---|
| Vsync and Vsync control signal in microcomputer Upper : Vsync signal Lower : Vsync control signal in microcomputer | <p>(n - 1) field (Odd-numbered)</p> <p>0.5 to 0.1 [ms] at f(BCLK) = 10 MHz</p> <p>T1</p> | Odd | / | / | / |
| | <p>(n) field (Even-numbered)</p> <p>T2</p> | Even | 0 (T2 > T1) | 0 1 | Dot line 1 <input type="checkbox"/> Dot line 0 <input checked="" type="checkbox"/> |
| | <p>(n + 1) field (Odd-numbered)</p> <p>T3</p> | Odd | 1 (T3 < T2) | 0 1 | Dot line 0 <input checked="" type="checkbox"/> Dot line 1 <input type="checkbox"/> |

When using the field determination flag, set bit 7 of the peripheral mode register (address 027D16) according to the main clock frequency.

OSD ROM font configuration diagram

Note : The field determination flag changes at a rising edge of the Vsync control signal (negative-polarity input) in the microcomputer.

Figure 2.16.18 Relation between field determination flag and display font

2.16.6 Memory for OSD

There are 2 types of memory for OSD : OSD ROM (addresses 9000₁₆ to AFFFF₁₆) used to store character dot data and OSD RAM (addresses 0400₁₆ to 13FF₁₆) used to specify the kinds of display characters, display colors, and SPRITE display. The following describes each type of memory.

(1) ROM for OSD (addresses 9000₁₆ to AFFFF₁₆)

The dot pattern data for OSD characters is stored in the character font area in the OSD ROM and the CD font data for OSD characters is stored in the color dot font area in the OSD ROM. To specify the kinds of the character font and the CD font, it is necessary to write the character code into the OSD RAM.

For character font, there are the following 2 mode.

- OSDL enable mode
16 X 20-dot font and 24 X 32-dot font
- OSDL disable mode
16 X 20-dot font

The modes are selected by bit 3 of the OSD control register 3 for each screen.

The character font data storing address for OSDL enable/OSDL disable mode are shown in Figures 2.16.20 and 2.16.21. The conditions for each OSDL enable/disable mode are shown in Figure 2.16.22. The CD font data storing address is shown in Figure 2.16.23.

and ON-SCREEN DISPLAY CONTROLLER

Depending on the relationship of OSDL enable/disable mode, display mode and character code, note the conditions below.

| OSDL enable/ disable mode Display mode & character code | | OSDL enable mode (Bit 0 of OSD control register 4 = "0") | | | | OSDL disable mode (Bit 0 of OSD control register 4 = "1") | | | |
|--|--|---|--------------------------|----------------------|--------------------------|--|-------------------------------------|-------------|-------------|
| | | Character size | CC | OSDS/P | OSDL | Character size | CC | OSDS/P | OSDL |
| Specified character code | 000 ₁₆ to 0FF ₁₆ | S | Used | Used | Not used (See note 3) | S | Used | Used | Display OFF |
| | 100 ₁₆ to 1FF ₁₆ | L | Used (See note 1) | Used (See note 1) | Used | S | Used | Used | Display OFF |
| | 200 ₁₆ to 27F ₁₆ | | Not used (See note 3) | | | S | | Used | Display OFF |
| | 280 ₁₆ to 2FF ₁₆ | | | | | Not used (See note 3) | Used (No border) (See note 2) | Display OFF | |
| | 300 ₁₆ to 3FF ₁₆ | | | | | Not used | Display OFF | | |

- Notes 1:** Part of 24 X 32 font is displayed.
- 2:** In OSDL disable mode, character codes "280₁₆" to "2FF₁₆" are used in OSDS/P mode (no border).
- 3:** As setting this make output of font data indeterminate, do not use. However, "3FE₁₆" and "3FF₁₆" can be used as character codes of blank font output in OSDP mode.

and ON-SCREEN DISPLAY CONTROLLER

(2) OSD RAM (OSD RAM for character, addresses 0400₁₆ to 0EFF₁₆)

The OSD RAM for character is allocated at addresses 0400₁₆ to 0EFF₁₆, and is divided into a display character code specification part, color code 1 specification part, and color code 2 specification part for each block. The number of characters for 1 block (32- or 42-character mode) is selected by bit 1 of the OSD control register 4. Tables 2.16.3 to 2.16.7 show the address map.

For example, to display 1 character position (the left edge) in block 1, write the character code in address 0400₁₆, write color code 1 at 0401₁₆, and write color code 2 at 0480₁₆. The structure of the OSD RAM is shown in Figure 2.16.25.

Note : For blocks of the following dot sizes, the 3rd (n = 1 to 14) character is skipped as compared with ordinary block.

■ In OSDL mode: all dot size.

■ In OSDS and CDOSD modes of layer 2: 1.5Tc X 1/2H or 1.5Tc X 1H

Accordingly, maximum 22 characters (32-character mode)/28 characters (42-character mode) are only displayed in 1 block. Blocks with dot size of 1Tc X 1/2H and 1Tc X 1H, or blocks on the layer 1. The RAM data for the 3rd character does not effect the display. Any character data can be stored here. And also, note the following only in 32-character mode. As the character is displayed in the 28th's character area in 42-character mode, set ordinarily.

- In OSDS mode

The character is not displayed, and only the left 1/3 part of the 22nd character background is displayed in the 22nd's character area. When not displaying this background, set transparent for character background color.

- In OSDL mode

Set a blank character or a character of transparent color to the 22nd character.

- In CDOSD mode

The character is not displayed, and color palette color specified by bits 3 to 6 of color code 1 can be output in the 22nd's character area (left 1/3 part).

(3) OSD RAM (OSD RAM for SPRITE, addresses 1000₁₆ to 13E7₁₆)

The OSD RAM for SPRITE fonts 1 and 2, consisting of 4 planes for each font, is assigned to addresses 1000₁₆ to 13E7₁₆. Each plane corresponds to each color palette selection bit and the color palette of each dot is determined from among 16 kinds.

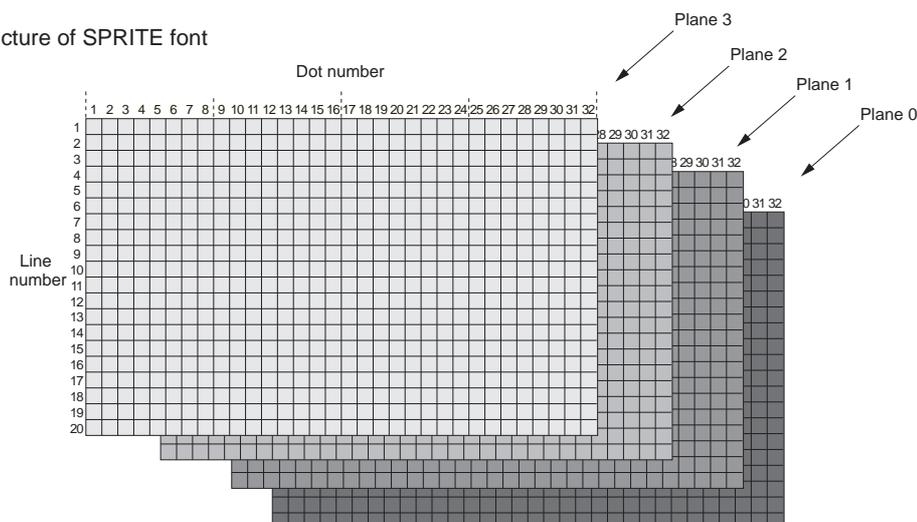

Table 2.16.8 OSD RAM address (SPRITE font 1)

| Planes | Plane 3 (Color palette selection bit 3) | | | | Plane 2 (Color palette selection bit 2) | | | | Plane 1 (Color palette selection bit 1) | | | | Plane 0 (Color palette selection bit 0) | | | |

Dot structure of SPRITE font

2.16.7 Character Color

As shown in Figure 2.16.26, there are 16 built-in color codes. Color palette 0 is fixed at transparent, and color palette 8 is fixed at black. The remaining 14 colors can be set to any of the 512 colors available. The setting procedure for character colors is as follows:

- CC mode 8 kinds
Color palette selection range (color palettes 0 to 7 or 8 to 15) can be selected by bit 0 of the OSD control register 3 (address 0207₁₆). Color palettes are set by bits RC11 to RC13 of the OSD RAM from among the selection range.
- OSDS/L/P mode 16 kinds
Color palettes are set by bits RC11 to RC14 of the OSD RAM.
- CDOSD mode 16 kinds
Color palettes are set in dot units according to CD font data.
Only in CDOSD mode, a dot which selects color palette 0 or 8 is colored to the color palette set by RC13 to RC16 of OSD RAM in character units (refer to Figure 2.16.28).
- SPRITE display 16 kinds
Color palettes are set in dot units according to the CD font data.

Notes 1: Color palette 8 is always selected for bordering and solid space output (OUT 1 output) regardless of the set value in the register.

2: Color palette 0 (transparent) and the transparent setting of other color palettes will differ. When there are multiple layers overlapping (on top of each other, piled up), and the priority layer is color palette 0 (transparent), the bottom layer is displayed, but if the priority layer is the transparent setting of any other color palette, the background is displayed without displaying the bottom layer (refer to Figure 2.16.28).

2.16.8 Character Background Color

The display area around the characters can be colored in with a character background color. Character background colors are set in character units.

- CC mode 4 kinds
Color palette selection range (color codes 0 to 3, 4 to 7, 8 to 11, or 12 to 15) can be selected by bits 1 and 2 of the OSD control register 3 (address 0207₁₆). Color palettes are set by bits RC20 and RC21 of the OSD RAM from among the selection range.
- OSDS/L/P mode 16 kinds
Color palettes are set by bits RC15, RC16, RC20, and RC21 of the OSD RAM.

Note: The character background is displayed in the following part:

(character display area) – (character font) – (border).

Accordingly, the character background color and the color signal for these two sections cannot be mixed.

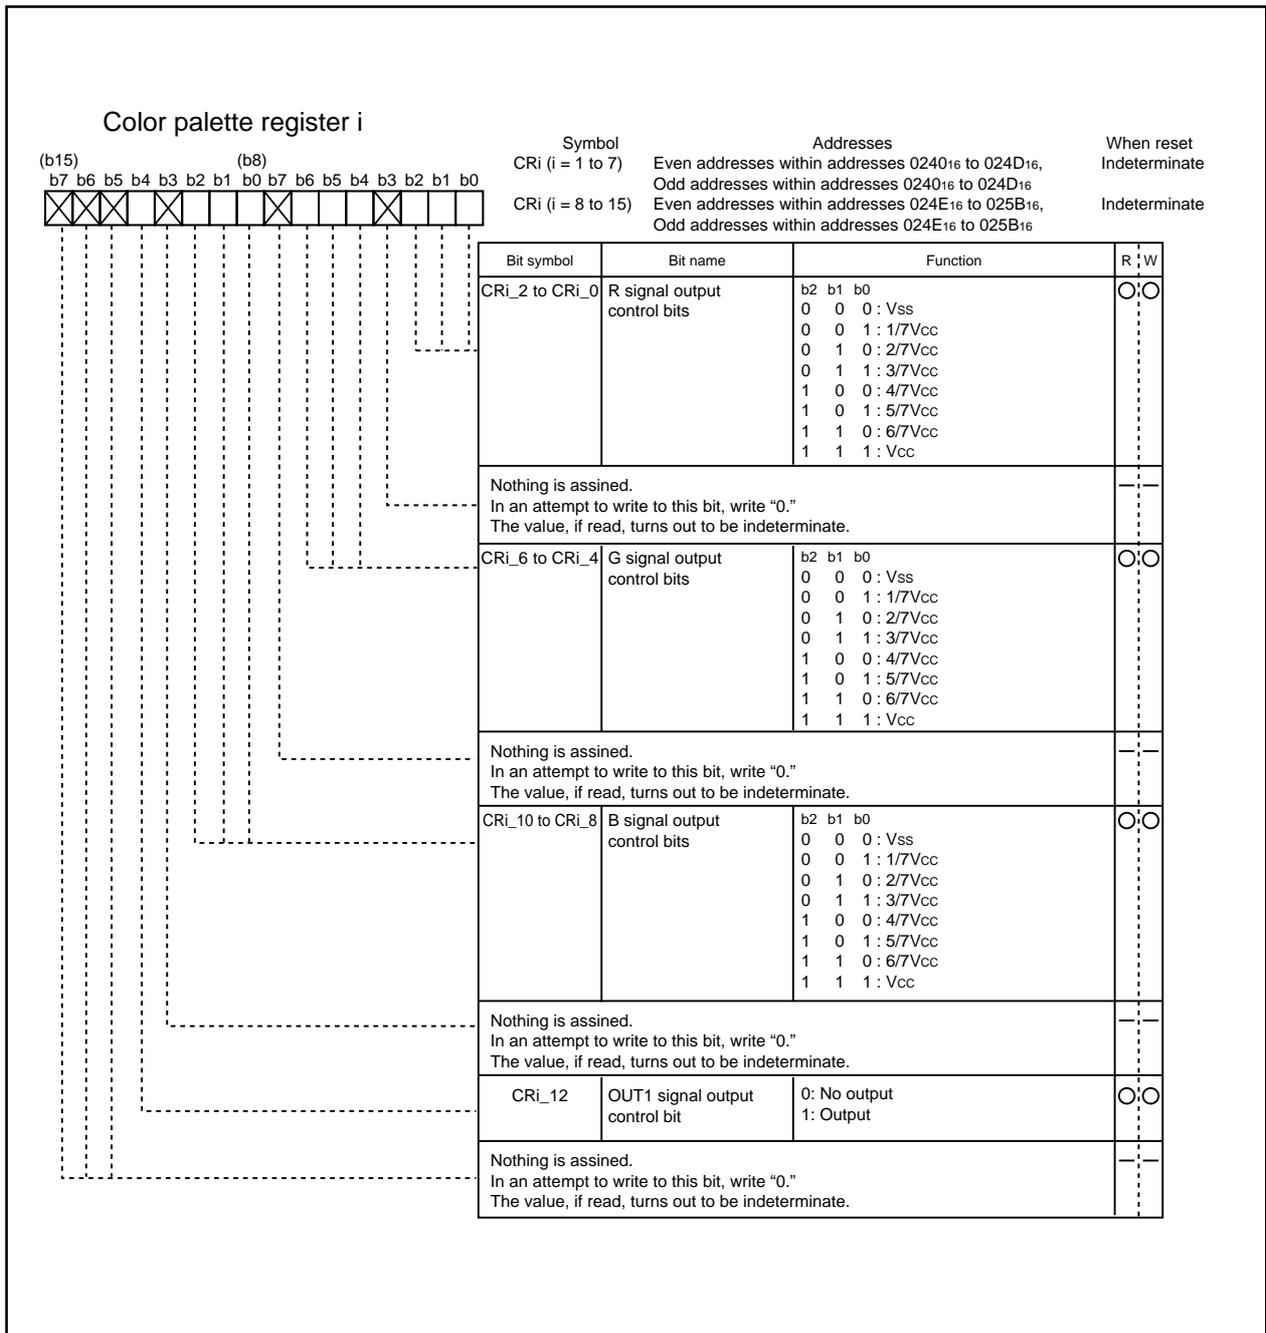

Figure 2.16.30 Color palette register i (i = 1 to 7, 9 to 15)

2.16.9 OUT1, OUT2 Signals

The OUT1, OUT2 signals are used to control the luminance of the video signal. The output waveform of the OUT1, OUT2 signals is controlled by bit 6 of the color palette register i (refer to Figure 2.16.30), bits 0 to 2 of the block control register i (refer to Figure 2.16.4) and RC17 of OSD RAM. The setting values for controlling OUT1, OUT2 and the corresponding output waveform is shown in Figure 2.16.31.

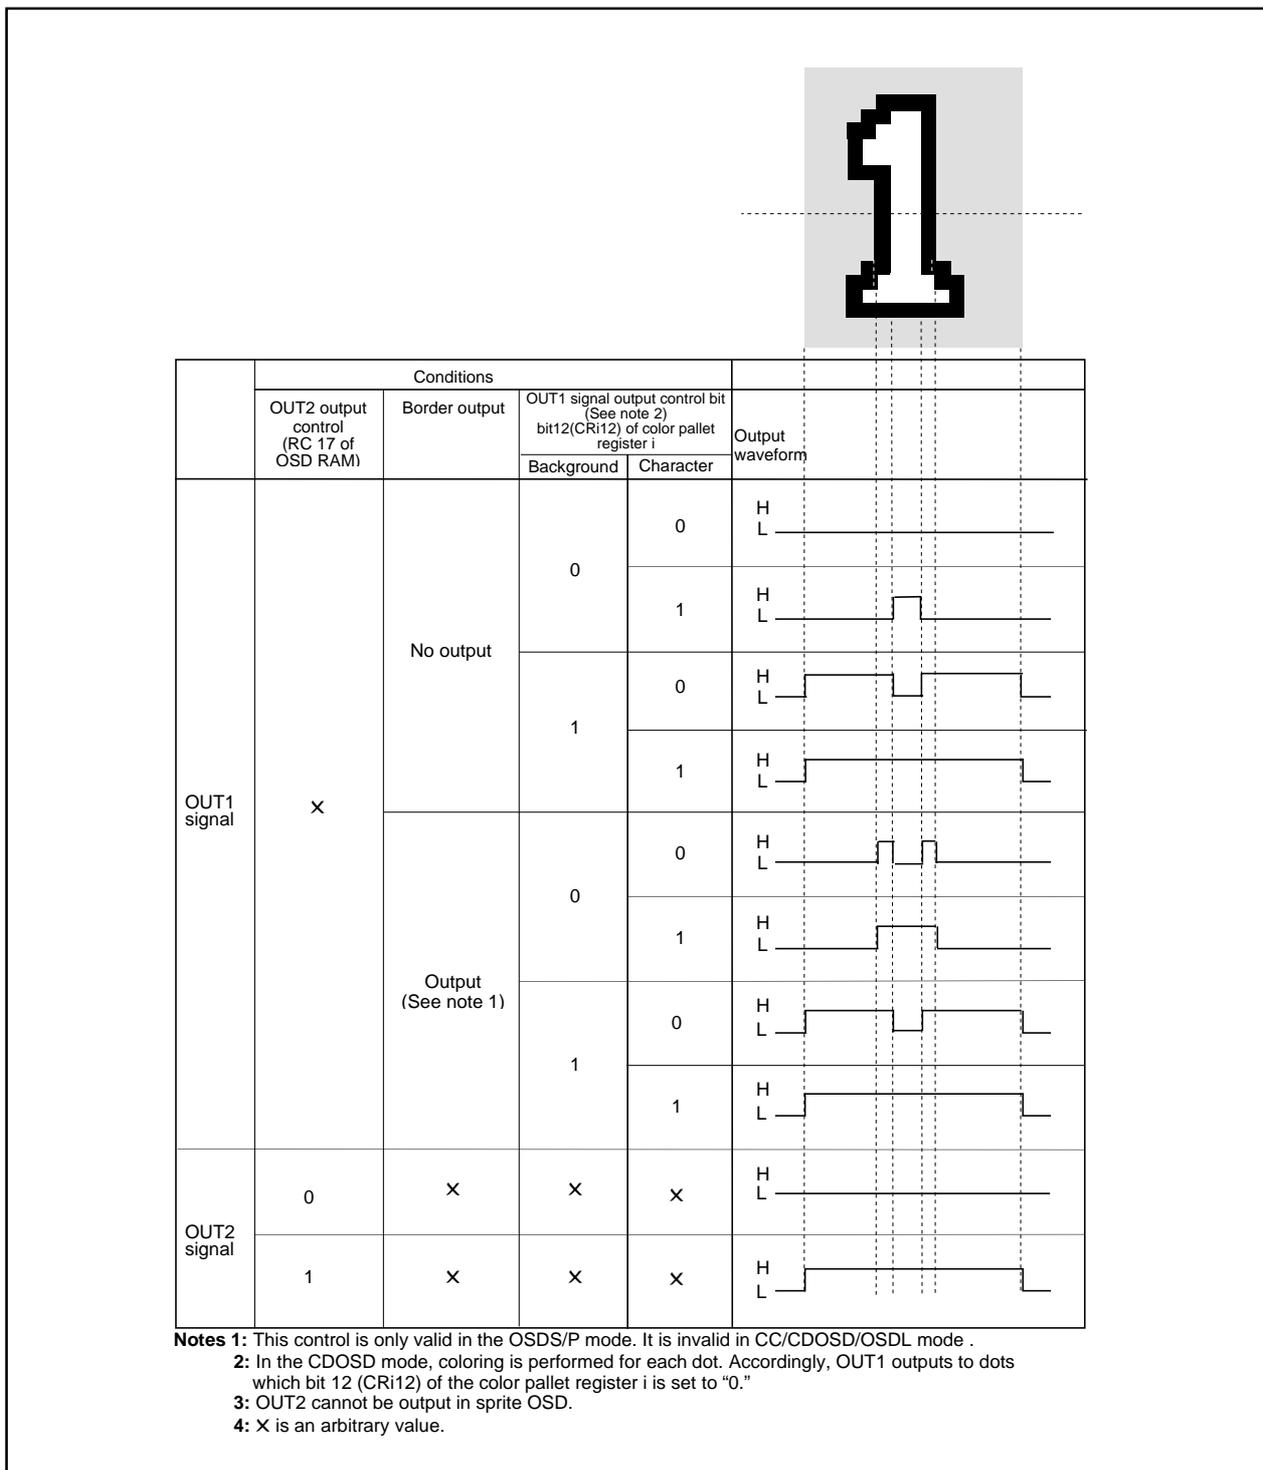

Figure 2.16.31 Setting value for controlling OUT1, OUT2 and corresponding output waveform

M306V5ME-XXXSP
M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
and ON-SCREEN DISPLAY CONTROLLER

2.16.10 Attribute

The attributes (flash, underline, italic fonts) are controlled to the character font. The attributes for each character are specified by RC14 to RC16 of OSD RAM (refer to Figure 2.16.26). The attributes to be controlled are different depending on each mode.

CC mode Flash, underline, italic for each character

OSDS/P mode Border (all bordered, shadow bordered can be selected) for each block

(1) Under line

The underline is output at the 23rd and 24th lines in vertical direction only in the CC mode. The underline is controlled by RC16 of OSD RAM. The color of underline is the same color as that of the character font.

(2) Flash

The parts of the character font, the underline, and the character background are flashed only in the CC mode. The flash for each character is controlled by RC15 of OSD RAM. The ON/OFF for flash is controlled by bit 3 of the OSD control register 1 (refer to Figure 2.16.3). When this bit is "0," only character font and underline flash. When "1," for a character without solid space output, R, G, B and OUT1 (all display area) flash, for a character with solid space output, only R, G, and B (all display area) flash. The flash cycle bases on the VSYNC count.

<NTSC method>

- When bit 4 = "0"
 - VSYNC cycle X 24 ≈ 400 ms (at flash ON)
 - VSYNC cycle X 8 ≈ 133 ms (at flash OFF)
- When bit 4 = "1"
 - VSYNC cycle X 48 ≈ 800 ms (at flash ON)
 - VSYNC cycle X 8 ≈ 133 ms (at flash OFF)

(3) Italic

The italic is made by slanting the font stored in OSD ROM to the right only in the CC mode. The italic is controlled by RC14 of OSD RAM.

The display example attribute is shown in Figure 2.16.33. In this case, "R" is displayed.

Notes 1: When setting both the italic and the flash, the italic character flashes.

2: When a flash character (with flash character background) adjoin on the right side of a non-flash italic character, parts out of the non-flash italic character is also flashed.

3: OUT2 is not flashed.

4: When the pre-divide ratio = 1, the italic character with slant of 1 dot X 5 steps is displayed ; when the pre-divide ratio = 2, the italic character with slant of 1/2 dot X 10 steps is displayed (refer to Figure 2.16.32 (c), (d)). However, when displaying the italic character with the pre-divide ratio = 1, set the OSD clock frequency to 11 MHz to 14 MHz.

5: The boundary of character color is displayed in italic. However, the boundary of character background color is not affected by the italic (refer to Figure 2.16.33).

6: The adjacent character (one side or both side) to an italic character is displayed in italic even when the character is not specified to display in italic (refer to Figure 2.16.33).

7: When displaying the 32nd character (in 32-character mode)/42nd character (in 42-character mode) in the italic and when solid space is off (OC14 = "0"), parts out of character area is not displayed (refer to Figure 2.16.33).

M306V5EESP

SINGLE-CHIP 16-BIT CMOS MICROCOMPUTER with CLOSED CAPTION DECODER
 and ON-SCREEN DISPLAY CONTROLLER

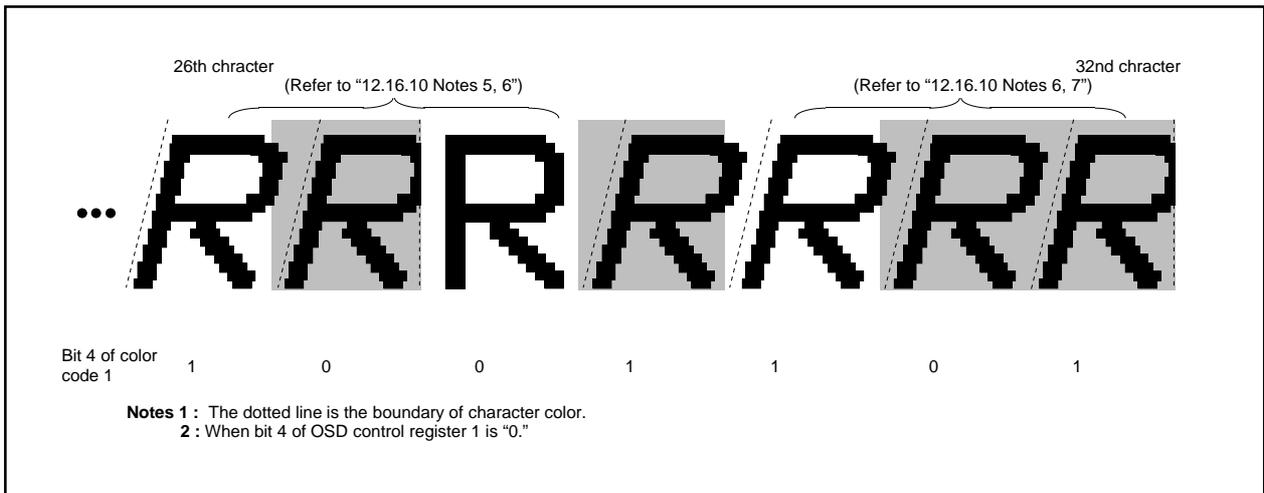

Figure 2.16.33 Example of italic display

(4) Border

The border is output in the OSDSP mode. The all bordered (bordering around of character font) and the shadow bordered (bordering right and bottom sides of character font) are selected (refer to Figure 2.16.34) by bit 2 of the OSD control register 1 (refer to Figure 2.16.3). The ON/OFF switch for borders can be controlled in block units by bits 0 to 2 of the block control register i (refer to Figure 2.16.4).

The OUT1 signal is used for border output. The border color is fixed at color palette 8 (black). The border color for each screen is specified by the border color register i.

The horizontal size (x) of border is 1Tc (OSD clock cycle divided in the pre-divide circuit) regardless of the character font dot size. However, only when the pre-divide ratio = 2 and character size = 1.5Tc, the horizontal size is 1.5Tc. The vertical size (y) different depending on the screen scan mode and the vertical dot size of character font.

Notes 1 : The border dot area is the shaded area as shown in Figure 2.16.36.

2 : When the border dot overlaps on the next character font, the character font has priority (refer to Figure 2.16.37 A). When the border dot overlaps on the next character back ground, the border has priority (refer to Figure 2.16.37 B).

3 : The border in vertical out of character area is not displayed (refer to Figure 2.16.38).

2.16.11 Automatic Solid Space Function

This function generates automatically the solid space (OUT1 or OUT2 blank output) of the character area in the CC mode.

The solid space is output in the following area :

- the character area except character code “009₁₆”
- the character area on the left and right sides

This function is turned on and off by bit 4 of the OSD control register 1 (refer to Figure 2.16.3).

OUT1 or OUT2 output is selected by bit 3 of the OSD control register 2.

Notes 1: When selecting OUT1 as solid space output, character background color with solid space output is fixed to color palette 8 (black) regardless of setting.

2: When selecting any font except blank font as the character code “009₁₆,” the set font is output.

Table 2.16.10 Setting for automatic solid space

| | | | | | | | | |
|---------------------------------|--|-------------------------|--|-------------------------|-------------------|-------------------------|--|---|

2.16.12 Particular OSD Mode Block

This function can display with mixing the fonts below within the OSDP mode block.

<horizontal dot structure with vertical dot structure of 20 dots>

- 16 dots
- 12 dots
- 8 dots
- 4 dots

Each font is selected by a character code. Figure 2.16.39 shows the display example of particular OSD mode block and Table 2.16.11 shows the corresponding between character codes and display fonts.

Note: As for 8 X 20-dot and 4 X 20-dot fonts, only these character background color can be displayed. And also, any character is not displayed on the right side area nor any following areas of these fonts.

| 3FE16 |  <p style="text-align: center;">8 dots</p> <p style="position: absolute; left: 328px; top: 485px; transform: rotate(-90deg);">20 dots</p> | <ul style="list-style-type: none"> • The blank font (only character background) is displayed. • Any character is not displayed on the right side area nor any following areas of this font. • Do not set this font for the 1st character (left edge) of a block. |
| 3FF16 |  <p style="text-align: center;">4 dots</p> <p style="position: absolute; left: 328px; top: 635px; transform: rotate(-90deg);">20 dots</p> | <ul style="list-style-type: none"> • The blank font (only character background) is displayed. • Any character is not displayed on the right side area nor any following areas of this font. • Do not set this font for the 1st character (left edge) of a block. |

2.16.13 Multiline Display

This microcomputer can ordinarily display 16 lines on the CRT screen by displaying 16 blocks at different vertical positions. In addition, it can display up to 16 lines by using OSD1 interrupts.

An OSD1 interrupt request occurs at the point at which display of each block has been completed. In other words, when a scanning line reaches the point of the display position (specified by the vertical position registers) of a certain block, the character display of that block starts, and an interrupt occurs at the point at which the scanning line exceeds the block. The mode in which an OSD1 interrupt occurs is different depending on the setting of the OSD control register 2 (refer to Figure 2.16.7).

- When bit 7 of the OSD control register 2 is "0"
An OSD1 interrupt request occurs at the completion of layer 1 block display.
- When bit 7 of the OSD control register 2 is "1"
An OSD1 interrupt request occurs at the completion of layer 2 block display.

Notes 1: An OSD1 interrupt does not occur at the end of display when the block is not displayed. In other words, if a block is set to off display by the display control bit of the block control register i (addresses 021016 to 021F16), an OSD1 interrupt request does not occur (refer to Figure 2.16.41 (A)).

2: When another block display appears while one block is displayed, an OSD1 interrupt request occurs only once at the end of the another block display (refer to Figure 2.16.40 (B)).

3: On the screen setting window, an OSD1 interrupt occurs even at the end of the CC mode block (off display) out of window (refer to Figure 2.16.40 (C)).

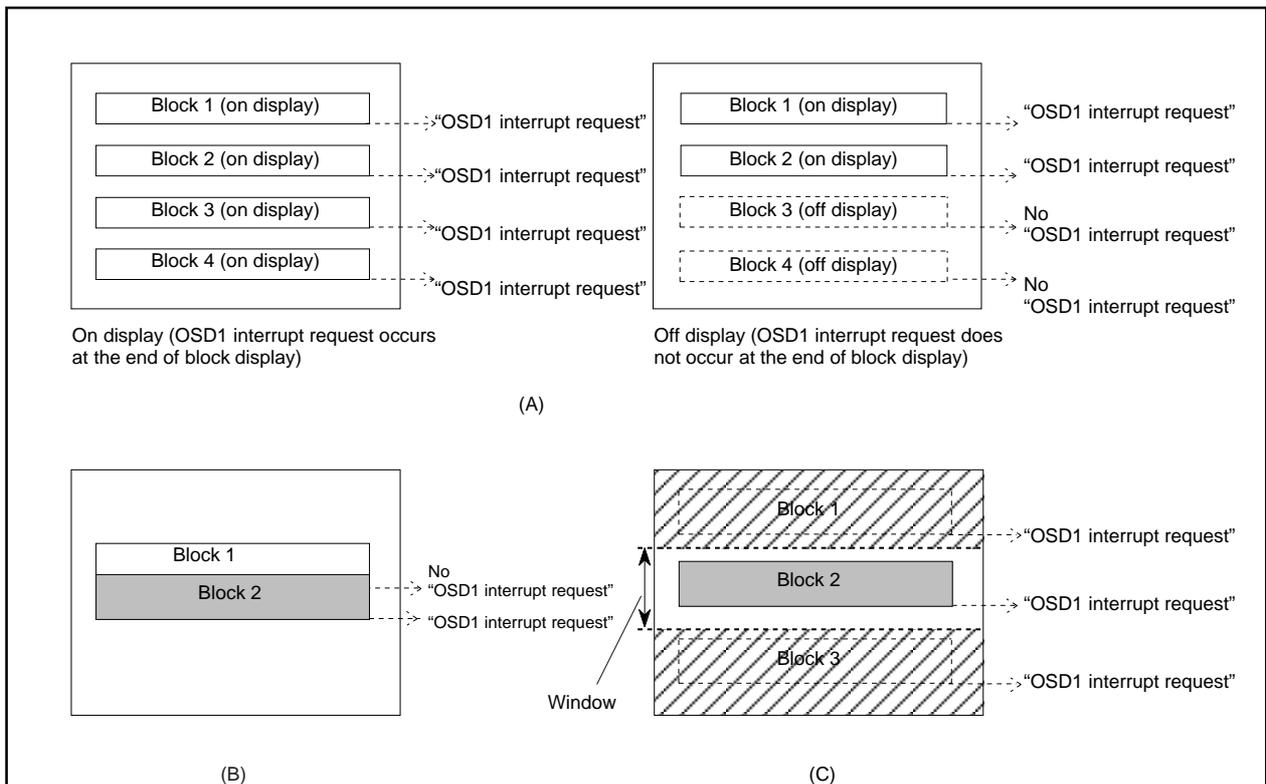

Figure 2.16.40 Note on occurrence of OSD1 interrupt

2.16.14 SPRITE OSD Function

This is especially suitable for cursor and other displays as its function allows for display in any position, regardless of the validity of block OSD displays or display positions. SPRITE font consists of 2 characters: SPRITE fonts 1 and 2. Each SPRITE font is a RAM font consisting of 32 horizontal dots X 20 vertical dots, 4 planes, and 4 bits of data per dot. Each plane has corresponding color palette selection bit, and 16 kinds of color palettes can be selected by the plane bit combination (three bits) for each dot. The color palette is set in dot units according to the OSD RAM (SPRITE) contents from among the selection range. It is possible to add arbitrary font data by software as the SPRITE fonts consist of RAM font.

The SPRITE OSD control register can control SPRITE display and dot size. The display position can also be set independently of the block display by the SPRITE horizontal position registers and the sprite horizontal vertical position registers. The vertical fonts 1 and 2 can be set independently. An OSD interrupt request occurs at each completion of font display. The horizontal position is set in 2048 steps in 2TOSC units, and the vertical position is set in 1024 steps in 1TH units.

When SPRITE display overlaps with other OSD displays, SPRITE display is always given priority. However, the SPRITE display overlaps with the display which includes OUT2 output, OUT2 in the OSD is output without masking.

Notes 1: The SPRITE OSD function cannot output OUT2.

2: When using SPRITE OSD, do not set $HS \leq "00316"$, $HS \geq "80016."$

3: When using SPRITE OSD, do not set $VSi = "00016,"$ $VSi \geq "40016."$

4: When displaying with SPRITE fonts 1 and 2 overlapped, the SPRITE font with a larger set value as the vertical display start position is displayed. When the set values of the vertical display start position are the same, the SPRITE font 1 is displayed.

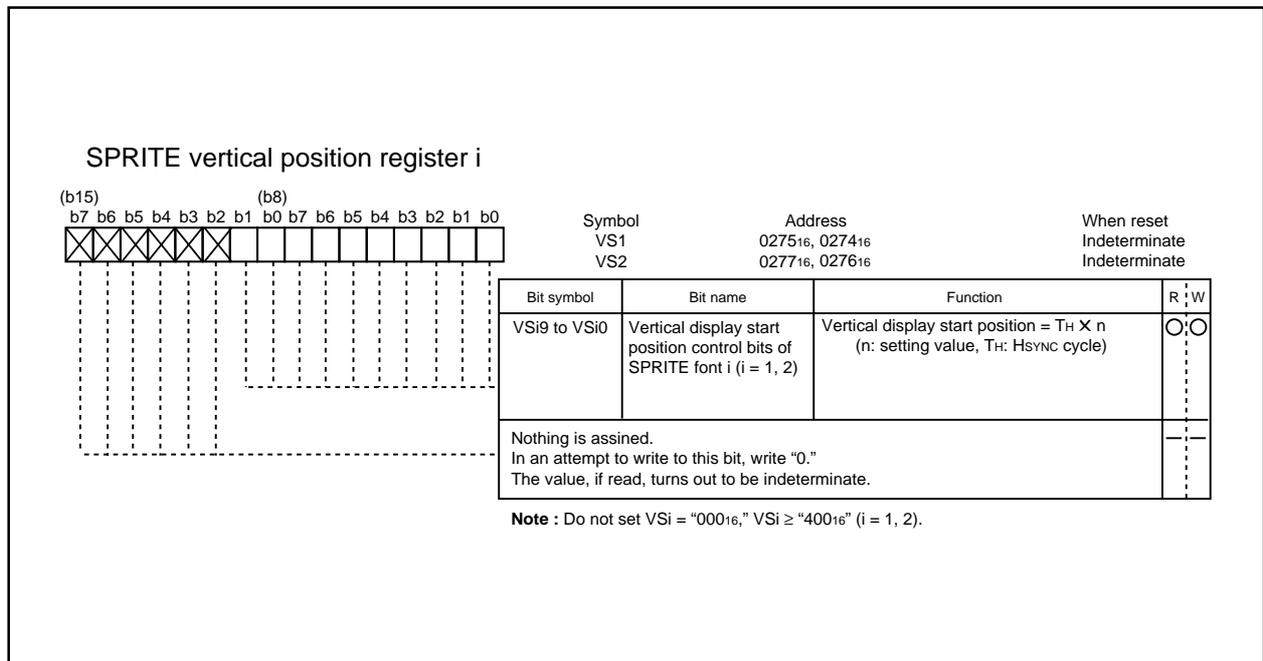

Figure 2.16.44 SPRITE vertical position register i (i = 1, 2)

2.16.15 Window Function

The window function can be set windows on-screen and output OSD within only the area where the window is set.

The ON/OFF for vertical window function is performed by bit 5 of the OSD control register 1 and is used to select vertical window function or vertical blank function by bit 6 of the OSD control register 2. Accordingly, the vertical window function cannot be used simultaneously with the vertical blank function. The display mode to validate the window function is selected by bits 5 to 7 of the OSD control register 3. The top border is set by the top border control register (TBR) and the bottom border is set by the bottom border control register (BBR).

The ON/OFF for horizontal window function is performed by bit 4 of the OSD control register 2 and is used interchangeably for the horizontal blank function with bit 5 of the OSD control register 2. Accordingly, the horizontal blank function cannot be used simultaneously with the horizontal window function. The display mode to validate the window function is selected by bits 5 to 7 of the OSD control register 3. The left border is set by the left border control register (LBR), and the right border is set by the right border control register (RBR).

- Notes 1:** Horizontal blank and horizontal window, as well as vertical blank and vertical window can not be used simultaneously.
- 2:** When the window function is ON by OSD control registers 1 and 2, the window function of OUT2 is valid in all display mode regardless of setting value of the OSD control register 3 (bits 5 to 7). For example, even when make the window function valid in only CC mode, the function of OUT2 is valid in OSDS/L/P and CDOSD modes.
- 3:** As for SPRITE display, the window function does not operate.

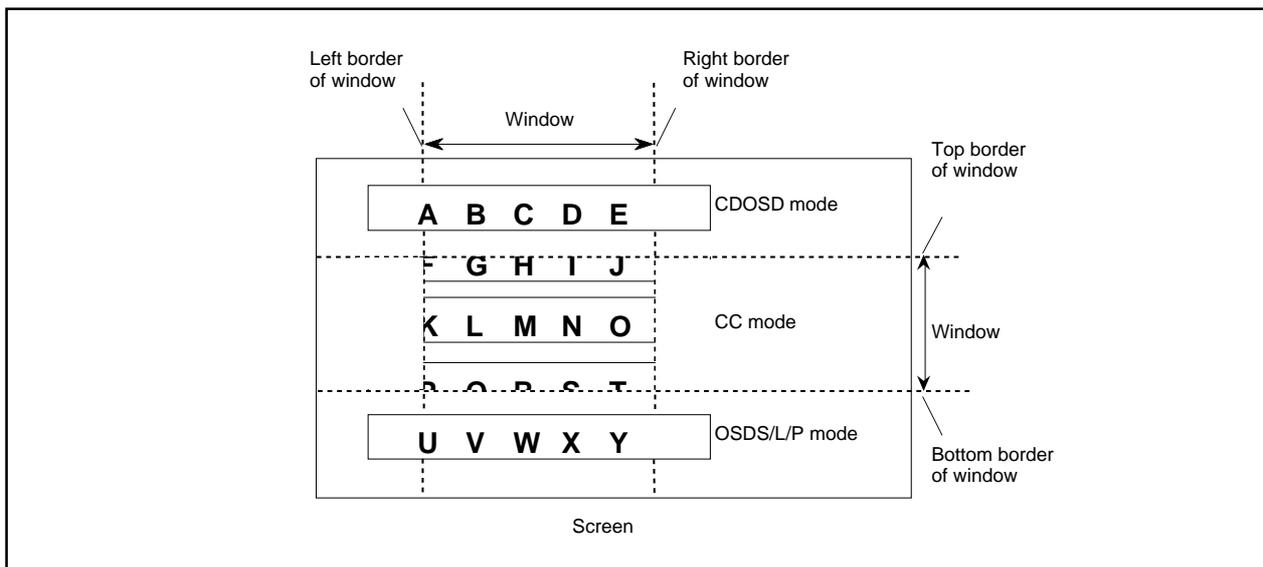

Figure 2.16.45 Example of window function (When CC mode is valid)

2.16.16 Blank Function

The blank function can output blank (OUT1) area on all sides (vertical and horizontal) of the screen. This provides the blank signal, wipe function, etc., when outputting a 3 : 4 image on a wide screen.

The ON/OFF for vertical blank function is performed by bit 5 of the OSD control register 1 and is used to select vertical window function or vertical blank function by bit 6 of the OSD control register 2. Accordingly, the vertical blank function cannot be used simultaneously with the vertical window function. The top border is set by the top border control register (TBR), and the bottom border is set by the bottom border control register (BBR), in 1H units.

The ON/OFF for horizontal blank function is performed by bit 4 of the OSD control register 2 and is used interchangeably for the horizontal window function with bit 5 of the OSD control register 2. Accordingly, the horizontal blank function cannot be used simultaneously with the horizontal window function. The left border is set by the left border control register (LBR) and the right border is set by the right border control register (RBR), in 4TOSC units.

The OSD output (except raster) in area with blank output is not deleted.

These blank signals are not output in the horizontal/vertical blanking interval.

- Notes 1.** Horizontal blank and horizontal window, as well as vertical blank and vertical window can not be used simultaneously.
- 2.** When using the window function, be sure to set “1” to bit 0 of OSD control register 1.

2.16.17 Raster Coloring Function

An entire screen (raster) can be colored by setting the bits 6 to 0 of the raster color register. Since each of the R, G, B, OUT1, and OUT2 pins can be switched to raster coloring output, 512 raster colors can be obtained.

When the character color/the character background color overlaps with the raster color, the color (R, G, B, OUT1, OUT2), specified for the character color/the character background color, takes priority of the raster color. This ensures that the character color/the character background color is not mixed with the raster color.

The raster color register is shown in Figure 2.16.51, the example of raster coloring is shown in Figure 2.16.52.

Note: Raster is not output to the area which includes blank area.

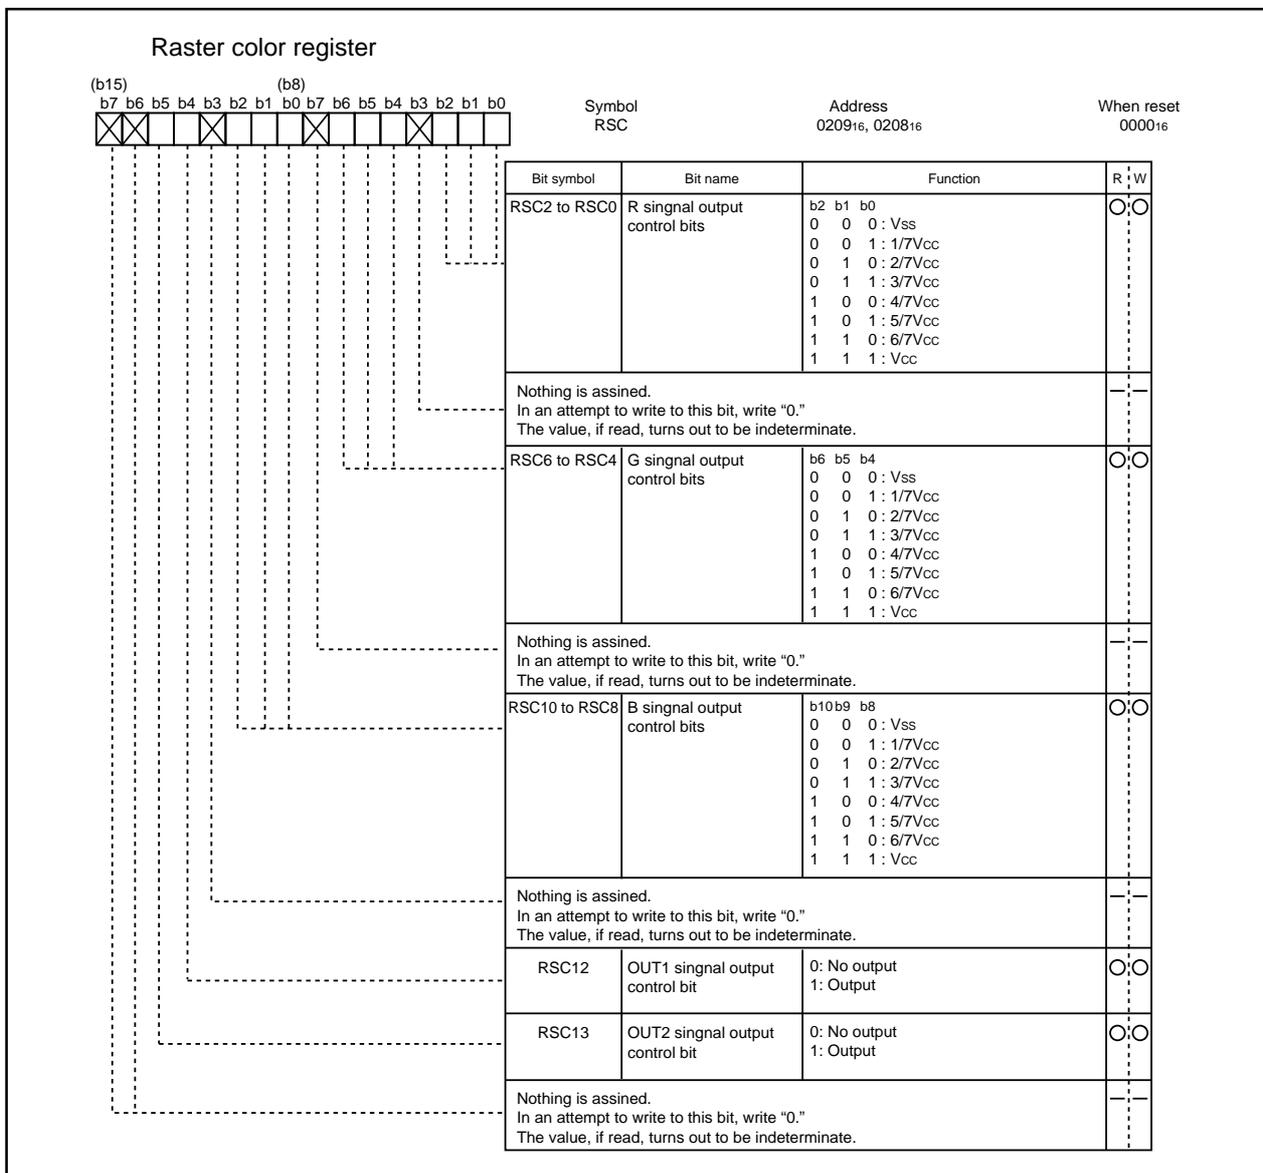

Figure 2.16.51 Raster color register

2.16.18 Scan Mode

This microcomputer has the bi-scan mode for corresponding to HSYNC of double speed frequency. In the bi-scan mode, the vertical start display position and the vertical size is two times as compared with the normal scan mode. The scan mode is selected by bit 1 of the OSD control register 1 (refer to Figure 2.16.3).

Table 2.16.12 Setting for scan mode

| Parameter | Scan Mode | Normal Scan | Bi-Scan |
|---------------------------------|-----------|--|--|
| Bit 1 of OSD control register 1 | | 0 | 1 |
| Vertical display start position | | Value of vertical position register X 1H | Value of vertical position register X 2H |
| Vertical dot size | | 1Tc X 1/2H | 1Tc X 1H |
| | | 1Tc X 1H | 1Tc X 2H |
| | | 2Tc X 2H | 2Tc X 4H |
| | | 3Tc X 3H | 3Tc X 6H |

2.16.19 R, G, B Signal Output Control

The form of R, G, B signal output is controlled by bit 2 of the OSD control register 2 as the table below.

Table 2.16.13 R, G, B signal output control

| Bit 2 of OSD control register 2 | Form of R, G, B signal output |
|---------------------------------|---|
| 0 | Each R, G, B pin outputs 2 values (digital output). |
| 1 | Each R, G, B pin outputs 8 values (analog output). |

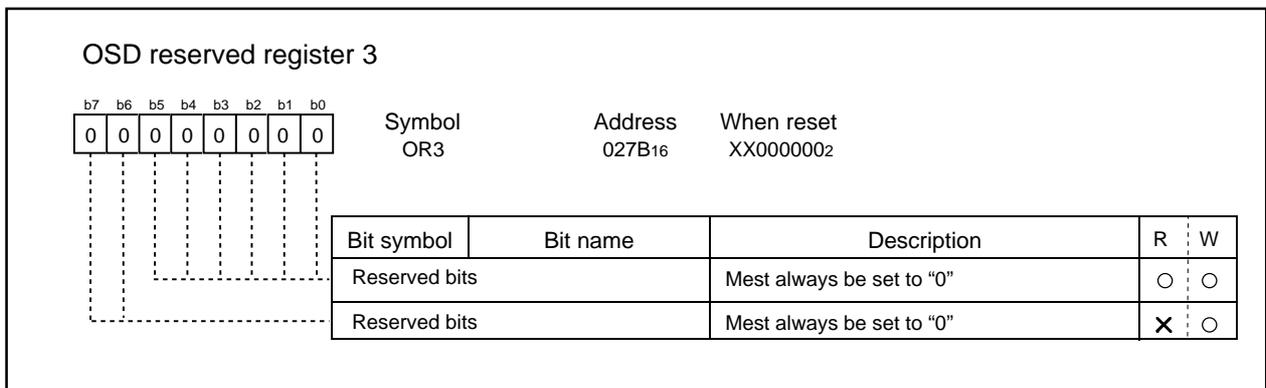

Figure 2.16.54 OSD reserved register 3

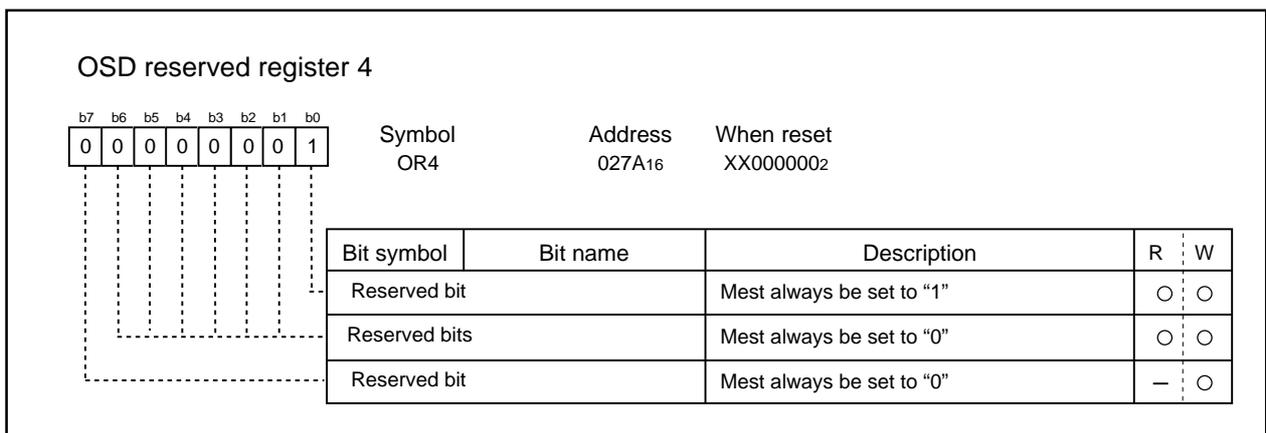

Figure 2.16.55 OSD reserved register 4

2.17 Programmable I/O Ports

There are 46 programmable I/O ports: P00–P07, P20–P27, P30–P37, P40–P43, P50, P52, P53, P62, P63, P67, P70–P72, P74, P76, P82, P90, P93, P94, P100 and P101. Each port can be set independently for input or output using the direction register. A pull-up resistance for each block of 4 ports can be set.

Figures 2.17.1 to 2.17.3 show the programmable I/O ports.

Each pin functions as a programmable I/O port and as the I/O for the built-in peripheral devices.

To use the pins as the inputs for the built-in peripheral devices, set the direction register of each pin to input mode. When the pins are used as the outputs for the built-in peripheral devices (other than the D-A converter), they function as outputs regardless of the contents of the direction registers. When pins are to be used as the outputs for the D-A converter, do not set the direction registers to output mode. See the descriptions of the respective functions for how to set up the built-in peripheral devices.

2.17.1 Direction Registers

Figures 2.17.5 to 2.17.12 show the direction registers.

These registers are used to choose the direction of the programmable I/O ports. Each bit in these registers corresponds one for one to each I/O pin.

(1) Effect of the protection register

Data written to the direction register of P9 is affected by the protection register. The direction register of P9 cannot be easily written.

2.17.2 Port Registers

Figures 2.17.13 to 2.17.20 show the port registers.

These registers are used to write and read data for input and output to and from an external device. A port register consists of a port latch to hold output data and a circuit to read the status of a pin. Each bit in port registers corresponds one for one to each I/O pin.

(1) Reading a port register

With the direction register set to output, reading a port register takes out the content of the port register, not the content of the pin. With the direction register set to input, reading the port register takes out the content of the pin.

(2) Writing to a port register

With the direction register set to output, the level of the written values from each relevant pin is output by writing to a port register. Writing to the port register, with the direction register set to input, inputs a value to the port register, but nothing is output to the relevant pins. The output level remains floating.

2.17.3 Pull-up Control Registers

Figures 2.17.24 to 2.17.26 show the pull-up control registers.

The pull-up control register can be set to apply a pull-up resistance to each block of 4 ports. When ports are set to have a pull-up resistance, the pull-up resistance is connected only when the direction register is set for input.

Table 2.17.1 Example connection of unused pins in single-chip mode

| Pin name | Connection |
|---------------------|--|
| Ports P0, P2 to P10 | After setting for input mode, connect every pin to Vss or Vcc via a resistor; or after setting for output mode, leave these pins open. |
| XOUT (Note) | Open |
| AVcc | Connect to Vcc |
| CNVss | Connect via resistor to Vss (pull-down) |

Note: With external clock input to XIN pin.

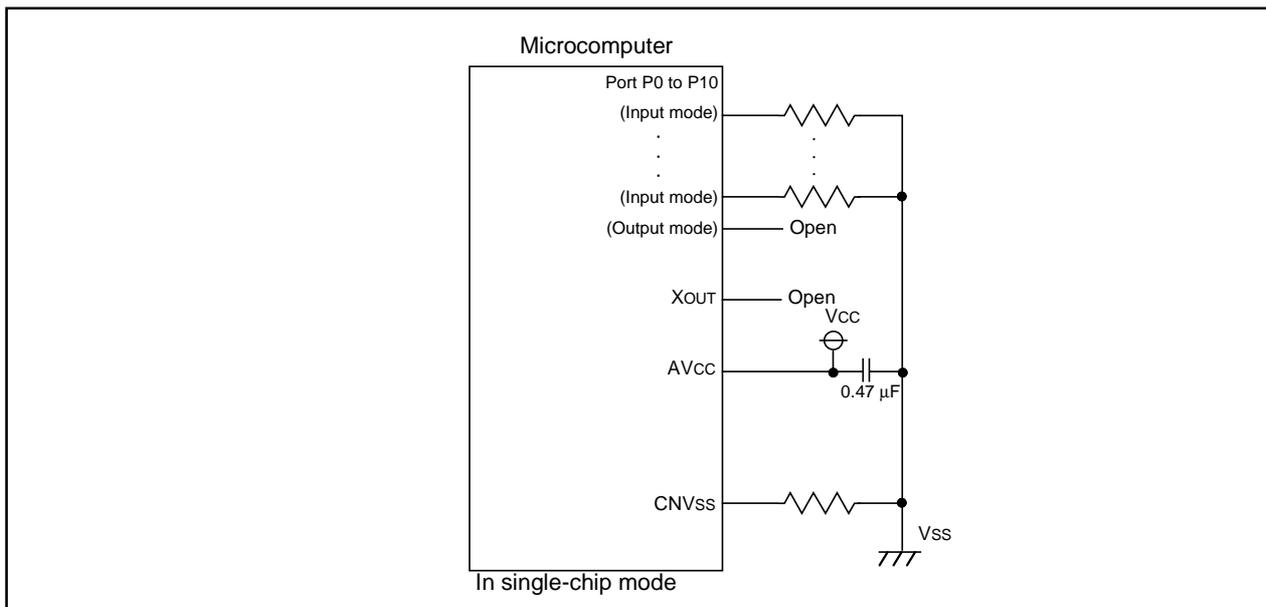

Figure 2.17.27 Example connection of unused pins

3. USAGE PRECAUTION

3.1 Timer A (timer mode)

- (1) Reading the timer Ai register while a count is in progress allows reading, with arbitrary timing, the value of the counter. Reading the timer Ai register with the reload timing gets "FFFF₁₆". Reading the timer Ai register after setting a value in the timer Ai register with a count halted but before the counter starts counting gets a proper value.

3.2 Timer A (event counter mode)

- (1) Reading the timer Ai register while a count is in progress allows reading, with arbitrary timing, the value of the counter. Reading the timer Ai register with the reload timing gets "FFFF₁₆" by underflow or "0000₁₆" by overflow. Reading the timer Ai register after setting a value in the timer Ai register with a count halted but before the counter starts counting gets a proper value.
- (2) When stop counting in free run type, set timer again.

3.3 Timer A (one-shot timer mode)

- (1) Setting the count start flag to "0" while a count is in progress causes as follows:
 - The counter stops counting and a content of reload register is reloaded.
 - The TAIOUT pin outputs "L" level.
 - The interrupt request generated and the timer Ai interrupt request bit goes to "1".
- (2) The timer Ai interrupt request bit goes to "1" if the timer's operation mode is set using any of the following procedures:
 - Selecting one-shot timer mode after reset.
 - Changing operation mode from timer mode to one-shot timer mode.
 - Changing operation mode from event counter mode to one-shot timer mode.Therefore, to use timer Ai interrupt (interrupt request bit), set timer Ai interrupt request bit to "0" after the above listed changes have been made.

3.4 Timer A (pulse width modulation mode)

- (1) The timer Ai interrupt request bit becomes "1" if setting operation mode of the timer in compliance with any of the following procedures:
 - Selecting PWM mode after reset.
 - Changing operation mode from timer mode to PWM mode.
 - Changing operation mode from event counter mode to PWM mode.Therefore, to use timer Ai interrupt (interrupt request bit), set timer Ai interrupt request bit to "0" after the above listed changes have been made.
- (2) Setting the count start flag to "0" while PWM pulses are being output causes the counter to stop counting. If the TAIOUT pin is outputting an "H" level in this instance, the output level goes to "L", and the timer Ai interrupt request bit goes to "1". If the TAIOUT pin is outputting an "L" level in this instance, the level does not change, and the timer Ai interrupt request bit does not becomes "1".

3.5 Timer B (timer mode, event counter mode)

- (1) Reading the timer Bi register while a count is in progress allows reading , with arbitrary timing, the value of the counter. Reading the timer Bi register with the reload timing gets "FFFF16". Reading the timer Bi register after setting a value in the timer Bi register with a count halted but before the counter starts counting gets a proper value.

3.6 Timer B (pulse period, pulse width measurement mode)

- (1) If changing the measurement mode select bit is set after a count is started, the timer Bi interrupt request bit goes to "1".
- (2) When the first effective edge is input after a count is started, an indeterminate value is transferred to the reload register. At this time, timer Bi interrupt request is not generated.

3.7 A-D Converter

- (1) Write to each bit (except bit 6) of A-D control register 0, to each bit of A-D control register 1, and to bit 0 of A-D control register 2 when A-D conversion is stopped (before a trigger occurs).
In particular, when the Vref connection bit is changed from "0" to "1", start A-D conversion after an elapse of 1 μ s or longer.
- (2) When changing A-D operation mode, select analog input pin again.
- (3) When using A-D converter in the one-shot mode and in the single sweep mode
After confirming the completion of A-D conversion, read the A-D register (the completion of A-D conversion is determined by A-D interrupt request bit).
- (4) When using A-D converter in the repeat mode and in the repeat sweep mode
Use the main clock without dividing as the internal clock of CPU.
- (5) The A-D conversion in the sweep mode needs the time as follows; (number of sweep pins + 2 pins) \times repeat times \times A-D conversion time for 1 pin.
- (6) When operating OSD or operating data slicer using the HSYNC and VSYNC input, do not use the A-D sweep mode (single sweep mode, repeat sweep mode 0, and repeat sweep mode 1).

3.8 Stop Mode and Wait Mode

- (1) When returning from stop mode by hardware reset, $\overline{\text{RESET}}$ pin must be set to "L" level until main clock oscillation is stabilized.
- (2) When switching to either wait mode or stop mode, instructions occupying four bytes either from the WAIT instruction or from the instruction that sets the every-clock stop bit to "1" within the instruction queue are perfected and then the program stops. So put at least four NOPs in succession either to the WAIT instruction or to the instruction that sets the every-clock stop bit to "1."

3.9 Interrupts

(1) Reading address 00000₁₆

- When maskable interrupt is occurred, CPU read the interrupt information (the interrupt number and interrupt request level) in the interrupt sequence.

The interrupt request bit of the certain interrupt written in address 00000₁₆ will then be set to "0". Reading address 00000₁₆ by software sets enabled highest priority interrupt source request bit to "0".

Though the interrupt is generated, the interrupt routine may not be executed.

Do not read address 00000₁₆ by software.

(2) Setting the stack pointer

- The value of the stack pointer immediately after reset is initialized to 0000₁₆. Accepting an interrupt before setting a value in the stack pointer may become a factor of runaway. Be sure to set a value in the stack pointer before accepting an interrupt.

(3) External interrupt

- When the polarity of the $\overline{\text{INT}}_0$ and $\overline{\text{INT}}_1$ pins is changed, the interrupt request bit is sometimes set to "1." After changing the polarity, set the interrupt request bit to "0."

(4) Rewrite the interrupt control register

- To rewrite the interrupt control register, do so at a point that does not generate the interrupt request for that register. If there is possibility of the interrupt request occur, rewrite the interrupt control register after the interrupt is disabled. The program examples are described as follow:

Example 1:

```
INT_SWITCH1:
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  NOP
  NOP
  FSET  I           ; Enable interrupts.
```

Example 2:

```
INT_SWITCH2:
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  MOV.W MEM, R0     ; Dummy read.
  FSET  I           ; Enable interrupts.
```

Example 3:

```
INT_SWITCH3:
  PUSHC FLG        ; Push Flag register onto stack
  FCLR  I           ; Disable interrupts.
  AND.B #00h, 0055h ; Clear TA0IC int. priority level and int. request bit.
  POPC  FLG        ; Enable interrupts.
```

The reason why two NOP instructions or dummy read are inserted before FSET I in Examples 1 and 2 is to prevent the interrupt enable flag I from being set before the interrupt control register is rewritten due to effects of the instruction queue.

- When a instruction to rewrite the interrupt control register is executed but the interrupt is disabled, the interrupt request bit is not set sometimes even if the interrupt request for that register has been generated. This will depend on the instruction. If this creates problems, use the below instructions to change the register.

Instructions : AND, OR, BCLR, BSET

3.10 Built-in PROM Version

3.10.1 All Built-in PROM Versions

High voltage is required to program to the built-in PROM. Be careful not to apply excessive voltage. Be especially careful during power-on.

3.10.2 One Time PROM Version

One Time PROM versions shipped in blank, of which built-in PROMs are programmed by users, are also provided. For these microcomputers, a programming test and screening are not performed in the assembly process and the following processes. To improve their reliability after programming, we recommend to program and test as flow shown in Figure 3.10.1 before use.

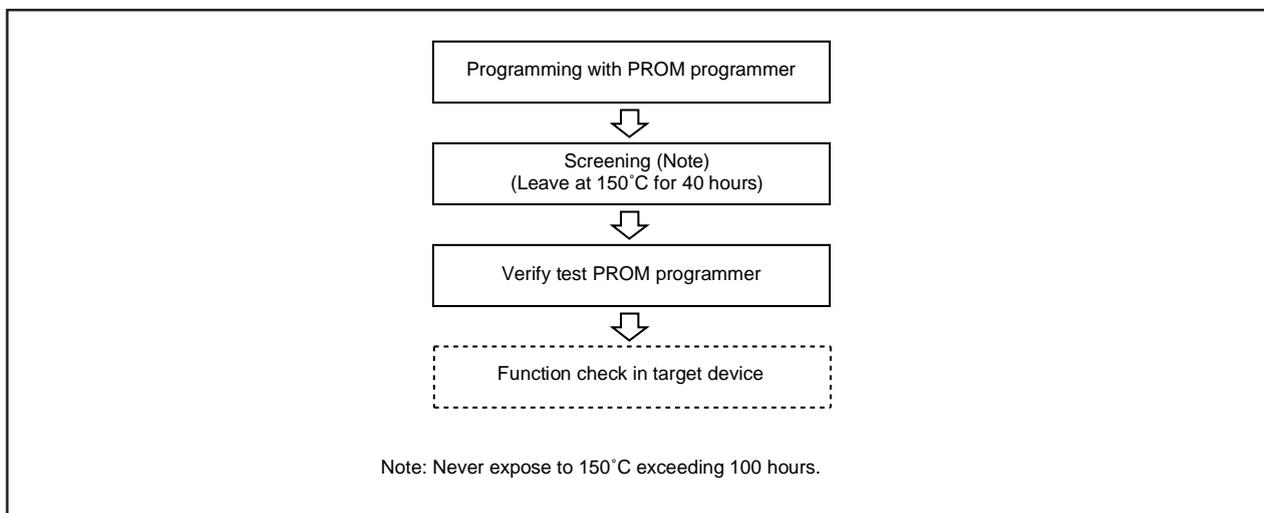

Figure 3.10.1 Programming and test flow for One Time PROM version

4. ITEMS TO BE SUBMITTED WHEN ORDERING MASKED ROM VERSION

Please submit the following when ordering masked ROM products.

- (1) Mask ROM confirmation form
- (2) Mask specification sheet
- (3) ROM data : EPROMs (3 sets)

*: In the case of EPROMs, three sets of EPROMs are required per pattern.

*: In the case of floppy disks, 3.5-inch double-sided high-density disk (IBM format) is required per pattern.

| f _{osc} | Oscillation frequency (for OSD) | OSC1 | LC oscillating mode | | 11.0 | 27.0 | MHz |
| | | | Ceramic oscillating mode | | 24.0 | 25.0 | |
| f _{CVIN} | Input frequency | Horizontal sync. signal of video signal | 15.262 | 15.743 | 16.206 | kHz | |
| V _I | Input amplitude video signal | CV _{IN} | 1.5 | 2.0 | 2.5 | V | |

Notes 1: The mean output current is the mean value within 100 ms.

2: The total I_{OL (peak)} for ports P0, P2, P9, and P10 must be 80 mA max. The total I_{OH (peak)} for ports P0, P2, P9, and P10 must be 80 mA max. The total I_{OL (peak)} for ports P3, P4, P5, P6, P7 and P82 must be 80 mA max. The total I_{OH (peak)} for ports P3, P4, P5, P6, P72, P74, P76, and P82 must be 80 mA max.

3: Connect 0.1 μF or more capacitor externally between the power source pins Vcc–Vss and AVcc–Vss so as to reduce power source noise. Also connect 0.1 μF or more capacitor externally between the power source pins Vcc–CNV_{SS}.

5.3 Electrical Characteristics

Table 5.3.1 Electrical characteristics (referenced to Vcc = 5 V, Vss = 0 V at Ta = 25 °C, f(XIN) = 10 MHz unless otherwise specified)

| Symbol | Parameter | Measuring condition | Standard | | | Unit | | |
|---------|---|--|---|--------------------------------|----------------------------------|------|----|----|
| | | | Min. | Typ. | Max. | | | |
| VoH | HIGH output voltage P00 to P07, P20 to P27, P30 to P37, P40 to P43, P50, P52, P53, P55, P62, P63, P67, P72, P74, P76, P82, P90, P93, P94, P100, P101, R, G, B, OUT1, OUT2 | IoH = -5 mA | 3.0 | | | V | | |
| VoH | HIGH output voltage P00 to P07, P20 to P27, P30 to P37, P40 to P43, P50, P52, P53, P55 | IoH = -200 μA | 4.7 | | | V | | |
| VoH | HIGH output voltage XOUT | HIGH POWER | 3.0 | | | V | | |
| | | LOW POWER | 3.0 | | | | | |
| VoL | LOW output voltage P00 to P07, P20 to P27, P30 to P37, P40 to P43, P50, P52, P53, P55, P62, P63, P74, P76, P82, P90, P100, P101, R, G, B, OUT1, OUT2 | IoL = 5 mA | | | 2.0 | V | | |
| VoL | LOW output voltage P67, P70 to P72, P93, P94 | IoL = 6.0 mA | | | 0.6 | V | | |
| VoL | LOW output voltage P00 to P07, P20 to P27, P30 to P37, P40 to P43, P50, P52, P53, P55 | IoL = 200 μA | | | 0.45 | V | | |
| VoL | LOW output voltage XOUT | HIGHPOWER | | | 2.0 | V | | |
| | | LOWPOWER | | | 2.0 | | | |
| Vt+-Vt- | Hysteresis TB0IN, INT0, INT1, CLK0, CLK2, SCL1, SCL2, SCL3, SDA1, SDA2, SDA3, Hsync, Vsync, HC0, HC1, RxD0, RxD2 | | 0.2 | | 0.8 | V | | |
| Vt+-Vt- | Hysteresis RESET | | 0.2 | | 1.8 | V | | |
| Vt+-Vt- | Hysteresis XIN | | 0.2 | | 0.8 | V | | |
| IiH | HIGH input current P00 to P07, P20 to P27, P30 to P37, P40 to P43, P50, P52, P53, P55, P62, P63, P67, P70, P71, P72, P74, P76, P82, P90, P93, P94, P100, P101 XIN, RESET, CNVss, OSC1 | Vi = 5 V | | | 5.0 | μA | | |
| IiL | LOW input current P00 to P07, P20 to P27, P30 to P37, P40 to P43, P50, P52, P53, P55, P62, P63, P67, P70, P71, P72, P74, P76, P82, P90, P93, P94, P100, P101 XIN, RESET, CNVss, OSC1 | Vi = 0 V | | | -5.0 | μA | | |
| PPULLUP | Pull-up resistor P00 to P07, P20 to P27, P30 to P37, P40 to P43, P50, P52, P53, P55, P62, P63, P67, P72, P74, P76, P82, P90, P93, P94 | Vi = 0 V | 30.0 | 50.0 | 167.0 | kΩ | | |
| Icc | Power supply current | In single-chip mode, the output pins are open and other pins are Vss | f(XIN) = 10 MHz Square wave, no division | OSD ON, Data slicer ON | 70 | 90 | mA | |
| | | | | OSD OFF, Data slicer OFF | 30 | 50 | | |
| | | | f(XIN) = 10 MHz Square wave, division by 8 | Ta=25 °C when clock is stopped | OSD OFF, Data slicer OFF | 10 | | mA |
| | | | | | Ta = 70 °C when clock is stopped | | 10 | |
| | | | | | 200 | | | |
| RBS | I ² C-BUS • BUS switch connection resistor (between SCL1 and SCL2, SDA1 and SDA2) | Vcc = 4.5 V | | | 130 | Ω | | |
| RiXIN | Feedback resistor XIN | | | 1.0 | | MΩ | | |
| RiXCIN | Feedback resistor XCIN | | | 6.0 | | MΩ | | |

5.4 A-D Conversion Characteristics

Table 5.4.1 A-D conversion characteristics (referenced to $V_{CC} = AV_{CC} = 5V$, $V_{SS} = AV_{SS} = 0V$ at $T_a = 25\text{ }^\circ\text{C}$, $f(X_{IN}) = 10\text{ MHz}$ unless otherwise specified)

| Symbol | Parameter | | Measuring condition | Standard | | | Unit |
|--------------|----------------------|--|-------------------------|----------|----------|----------|-----------|
| | | | | Min. | Typ. | Max. | |
| — | Resolution | | $V_{REF} = V_{CC}$ | | | 8 | Bits |
| — | Absolute accuracy | Sample & hold function not available | $V_{REF} = V_{CC} = 5V$ | | | ± 5 | LSB |
| | | Sample & hold function available (8 bit) | $V_{REF} = V_{CC} = 5V$ | | | ± 5 | LSB |
| R_{LADDER} | Ladder resistance | | $V_{REF} = V_{CC}$ | 10 | | 40 | $k\Omega$ |
| t_{CONV} | Conversion time | | | 2.8 | | | μs |
| t_{SAMP} | Sampling time | | | 0.3 | | | μs |
| V_{REF} | Reference voltage | | | | V_{CC} | | V |
| V_{IA} | Analog input voltage | | | 0 | | V_{CC} | V |

5.5 D-A Conversion Characteristics

Table 5.5.1 D-A conversion characteristics (referenced to $V_{CC} = 5V$, $V_{SS} = AV_{SS} = 0V$ at $T_a = 25\text{ }^\circ\text{C}$, $f(X_{IN}) = 10\text{ MHz}$ unless otherwise specified)

| Symbol | Parameter | | Measuring condition | Standard | | | Unit |
|------------|--------------------------------------|--|---------------------|----------|------|------|-----------|
| | | | | Min. | Typ. | Max. | |
| — | Resolution | | | | | 8 | Bits |
| — | Absolute accuracy | | | | | 10 | % |
| t_{su} | Setup time | | | | | 3 | μs |
| R_o | Output resistance | | | 4 | 10 | 20 | $k\Omega$ |
| I_{VREF} | Reference power supply input current | | (Note) | | | 1.5 | mA |

Note: This applies when using one D-A converter, with the D-A register for the unused D-A converter set to "0016."
The A-D converter's ladder resistance is not included.
Also, when the V_{ref} is unconnected at the A-D control register, I_{VREF} is sent.

5.6 Analog R, G, B Output Characteristics

Table 5.6.1 Analog R, G, B output characteristics ($V_{CC} = 5V$, $V_{SS} = 0V$ at $T_a = 25\text{ }^\circ\text{C}$, $f(X_{IN}) = 10\text{ MHz}$ unless otherwise specified)

| Symbol | Parameter | | Test conditions | Standard | | Unit |
|----------|------------------|--|---|----------|-----------|-----------|
| | | | | Min. | Max. | |
| R_O | Output impedance | | | | 2 | $k\Omega$ |
| V_{OE} | Output deviation | | | | ± 0.5 | V |
| T_{ST} | Settling time | | load capacity of 10 pF, load resistance of 20 $k\Omega$, 70 % DC level | | 50 | ns |

| ※ Customer | Company name | TEL () | Issuance signature | Submitted by | Supervisor |
| | Date issued | Date : | | | |

※ 1. Check sheet

Name the product you order, and choose which to give in, EPROMs or floppy disks.
If you order by means of EPROMs, three sets of EPROMs are required per pattern. If you order by means of floppy disks, one floppy disk is required per pattern.

In the case of EPROMs

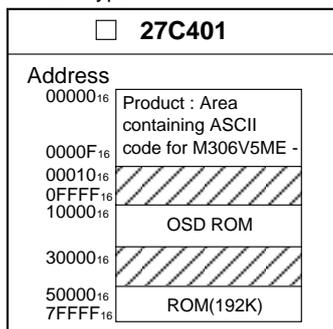

Mitsubishi will create the mask using the data on the EPROMs supplied, providing the data is the same on at least two of those sets. Mitsubishi will, therefore, only accept liability if there is any discrepancy between the data on the EPROM sets and the ROM data written to the product.
Please carefully check the data on the EPROMs being submitted to Mitsubishi.

Checksum code for total EPROM area :

| | | | |
|--|--|--|--|
| | | | |
|--|--|--|--|

 (hex)

EPROM type :

- (1) The area from 00000₁₆ to 0000F₁₆ is for storing data on the product type name.
The ASCII code for 'M306V5ME-' is shown at right.
The data in this table must be written to address 00000₁₆ to 0000F₁₆.
Both address and data are shown in hex.
- (2) Write "FF₁₆" to the lined area.

| | | | |
|---------------------|------------------------|---------------------|------------------------|
| Address | 'M' = 4D ₁₆ | Address | '—' = 2D ₁₆ |
| 00000 ₁₆ | '3' = 33 ₁₆ | 00008 ₁₆ | FF ₁₆ |
| 00001 ₁₆ | '0' = 30 ₁₆ | 00009 ₁₆ | FF ₁₆ |

and ON-SCREEN DISPLAY CONTROLLER

GZZ—SH56—45B <93A0>

**MITSUBISHI ELECTRIC SINGLE-CHIP 16-BIT
MICROCOMPUTER M306V5ME-XXXSP
MASK ROM CONFIRMATION FORM**

| | |
|-----------------|--|
| Mask ROM number | |
|-----------------|--|

The ASCII code for the type No. can be written to EPROM addresses 00000₁₆ to 0000F₁₆ by specifying the pseudo-instructions shown in the following table at the beginning of the assembler source program.

| | |
|--------------------------------|--|
| EPROM type | 27C401 |
| Code entered in source program | △ .SECTION △ ASCII CODE, ROM DATA △ .ORG △ 080000H △ .BYTE △ ' M306V5ME- ' |

Note: The ROM cannot be processed if the type No. written to the EPROM does not match the type No. in the check sheet.

In the case of floppy disks

Mitsubishi processes the mask files generated by the mask file generation utilities out of those held on the floppy disks you give in to us, and forms them into masks. Hence, we assume liability provided that there is any discrepancy between the contents of these mask files and the ROM data to be burned into products we produce. Check thoroughly the contents of the mask files you give in. Prepare 3.5 inches 2HD(IBM format) floppy disks. And store only one mask file in a floppy disk.

File code :

| | | | | | | | |
|--|--|--|--|--|--|--|--|
| | | | | | | | |
|--|--|--|--|--|--|--|--|

 (hex)

Mask file name :

| | | | | | | | |
|--|--|--|--|--|--|--|--|
| | | | | | | | |
|--|--|--|--|--|--|--|--|

 .MSK (alpha-numeric 8-digit)

Note: When using the floppy disks, do not store the type No. to addresses 0000₁₆ to 0000F₁₆.

※2. Mark specification

The mark specification differs according to the type of package. After entering the mark specification on the separate mark specification sheet (for each package), attach that sheet to this masking check sheet for submission to Mitsubishi.

For the M306V5ME-XXXSP, submit the 64P4B mark specification sheet.

※ 3. Usage Conditions

For our reference when of testing our products, please reply to the following questions about the usage of the products you ordered.

(1) Which kind of X_{IN}-X_{OUT} oscillation circuit is used?

- Ceramic resonator Quartz-crystal oscillator
 External clock input Other ()

What frequency do you use?

f(X_{IN}) = MHz

(2) Which operation mode do you use?

- Single-chip mode Memory expansion mode
 Microprocessor mode

Thank you cooperation.

7. MARK SPECIFICATION FORM

64P4B (64-PIN SHRINK DIP) MARK SPECIFICATION FORM

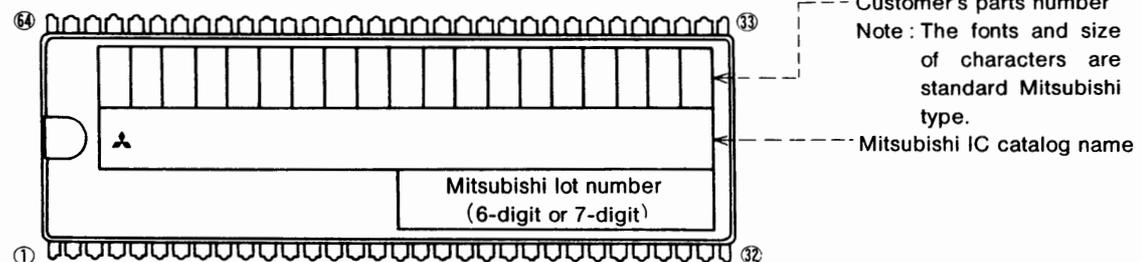

Mitsubishi IC catalog name

Please choose one of the marking types below (A, B, C), and enter the Mitsubishi IC catalog name and the special mark (if needed).

A. Standard Mitsubishi Mark

B. Customer's Parts Number + Mitsubishi Catalog Name

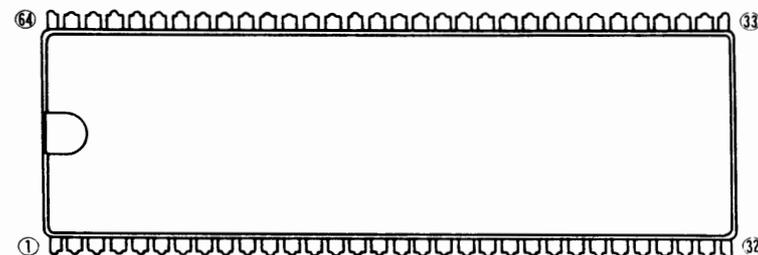

Note1 : The mark field should be written right aligned.

- 2 : The fonts and size of characters are standard Mitsubishi type.
- 3 : Customer's parts number can be up to 19 characters :
Only 0~9, A~Z, +, -, /, (,), &, ©, . (period), and , (comma) are usable.
- 4 : If the Mitsubishi logo is not required, check the box on the right.

Mitsubishi logo is not required

C. Special Mark Required

Note1 : If the special mark is to be printed, indicate the desired layout of the mark in the upper figure. The layout will be duplicated as close as possible. Mitsubishi lot number (6-digit or 7-digit) and mask ROM number (3-digit) are always marked.

2 : If the customer's trade mark logo must be used in the special mark, check the box below. Please submit a clean original of the logo.

For the new special character fonts a clean font original (ideally logo drawing) must be submitted.

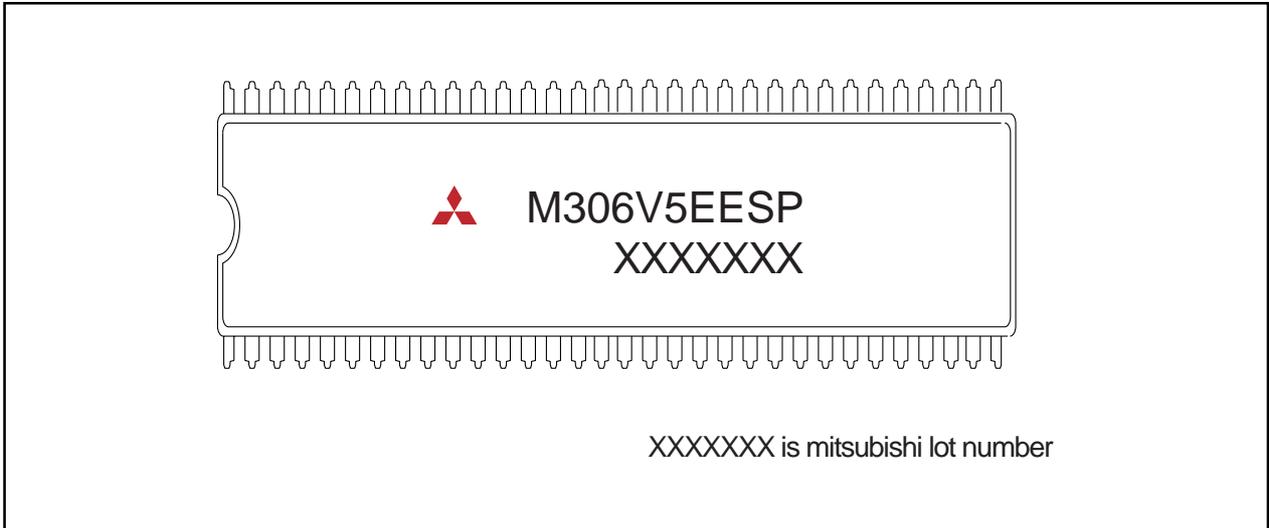

Special logo required

The standard Mitsubishi font is used for all characters except for a logo.

Structure of Register

Refer to the figure below as for each register.

<Example>

Processor mode register 1 (Note)

Values immediately after reset release (Note 1)

When reset: 0000X002

Bit attributes (Note 2)

| | | | | | | | | | | |
|----|----|----|----|----|----|----|----|--------|---------|--|
| b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 | Symbol | Address | |
| 0 | 0 | 0 | 0 | X | 1 | 0 | | PM1 | 000516 | |

| Bit symbol | Bit name | Function | R:W |
|------------|---|--|-----|
| | Reserved bit | Must always be set to "0" | ○:○ |
| | Reserved bit | Must always be set to "1" | ○:○ |
| | Nothing is assigned. In an attempt to write to this bit, write "0." The value, if read, turns out to be indeterminate. | | —:— |
| | Reserved bits | Must always be set to "0" | —:○ |
| PM17 | Wait bit | 0 : No wait state 1 : Wait state inserted | ○:○ |

Note: As bit 1 of this register becomes "0" at reset, must always be set to "1" after reset release. Set bit 1 of the protect register (address 000A16) to "1" when writing new values to this register.

⊗ : Bit in which nothing is assigned

Notes 1: Values immediately after reset release
 0 "0" after reset release
 1 "1" after reset release
 ? Indeterminate after reset release
 X Bit in which nothing is assigned

2: Bit attributes The attributes of control register bits are classified into 3 types : read-only, write-only and read and write. In the figure, these attributes are represented as follows :

R Read
 ○ Read enabled
 X Read disabled
 — Bit in which nothing is assigned (The read value is indeterminate unless otherwise mentioned.)

W Write
 ○ Write enabled
 X Write disabled
 — Bit in which nothing is assigned

Keep safety first in your circuit designs!

- Mitsubishi Electric Corporation puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of non-flammable material or (iii) prevention against any malfunction or mishap.

Notes regarding these materials

- These materials are intended as a reference to assist our customers in the selection of the Mitsubishi semiconductor product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Mitsubishi Electric Corporation or a third party.
- Mitsubishi Electric Corporation assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
- All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Mitsubishi Electric Corporation without notice due to product improvements or other reasons. It is therefore recommended that customers contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for the latest product information before purchasing a product listed herein.
- The information described here may contain technical inaccuracies or typographical errors. Mitsubishi Electric Corporation assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors. Please also pay attention to information published by Mitsubishi Electric Corporation by various means, including the Mitsubishi Semiconductor home page (<http://www.mitsubishichips.com>).
- When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Mitsubishi Electric Corporation assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
- Mitsubishi Electric Corporation semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- The prior written approval of Mitsubishi Electric Corporation is necessary to reprint or reproduce in whole or in part these materials.
- If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.
- Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
- Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for further details on these materials or the products contained therein.
