# MC68HC708MP16 Data Sheet

M68HC08 Microcontrollers

Rev. 3.1 MC68HC708MP16/D July 28, 2005

# **List of Sections**

Section 1. General Description
Section 2. Memory Map
Section 3. Random-Access Memory (RAM) 53
Section 4. EPROM/OTPROM
Section 5. Configuration Register (CONFIG) 59
Section 6. Central Processor Unit (CPU) 63
Section 7. System Integration Module (SIM)
Section 8. Clock Generator Module (CGM) 103
Section 9. Pulse Width Modulator for Motor Control (PWMMC) 129
Section 10. Monitor ROM (MON)
Section 11. Timer Interface Module A (TIMA) 201
Section 12. Timer Interface Module B (TIMB) 225
Section 13. Serial Peripheral Interface Module (SPI)
Section 14. Serial Communications Interface  Module (SCI)
Section 15. Input/Output (I/O) Ports
Section 16. Computer Operating Properly (COP)
Section 17. External Interrupt (IRQ)

MC68HC708MP16 - Rev. 3.1

# **List of Sections**

Section 18. Low-Voltage Inhibit (LVI)	347
Section 19. Analog-to-Digital Converter (ADC)	353
Section 20. Power-On Reset (POR)	365
Section 21. Electrical Specifications	367
Section 22. Mechanical Specifications	379
Section 23. Ordering Information	381
Glossary	383

# **Table of Contents**

### **Section 1. General Description**

1.1	Contents	29
1.2	Introduction	30
1.3	Features	30
1.4	MCU Block Diagram	31
1.5	Pin Assignments	33
1.5.1	Power Supply Pins (V <sub>DD</sub> and V <sub>SS</sub> )	35
1.5.2	Oscillator Pins (OSC1 and OSC2)	35
1.5.3		35
1.5.4	External Interrupt Pin (IRQ1/V <sub>PP</sub> )	36
1.5.5		36
1.5.6	External Filter Capacitor Pin (CGMXFC)	36
1.5.7	Analog Power Supply Pins	
	(V <sub>DDAD</sub> /V <sub>DDAREF</sub> and V <sub>SSAD</sub> )	36
1.5.8	ADC Voltage Decoupling Capacitor Pin (V <sub>ADCAP</sub> )	36
1.5.9	ADC Voltage Reference Low Pin (V <sub>REFL</sub> )	37
1.5.10	Port A Input/Output (I/O) Pins (PTA7–PTA0)	37
1.5.11	Port B I/O Pins (PTB7/ATD7–PTB0/ATD0)	37
1.5.12		
	and PTC1/ATD9-PTC0/ATD8)	37
1.5.13		
	and PTD3/FAULT4-PTD0/FAULT1)	37
1.5.14	PWM Pins (PWM6–PWM1)	38
1.5.15	PWM Ground Pin (PWMGND)	38
1.5.16	Port E I/O Pins (PTE7/TCH3B-PTE3/TCLKB	
	·	38
1.5.17	Port F I/O Pins (PTF5/TxD-PTF4/RxD	
	and PTF3/MISO-PTF0/SPSCK)	38

MC68HC708MP16 — Rev. 3.1

#### 1.2 Introduction

The MC68HC708MP16 is a member of the low-cost, high-performance M68HC08 Family of 8-bit microcontroller units (MCUs). The M68HC08 Family is based on the customer-specified integrated circuit (CSIC) design strategy. All MCUs in the family use the enhanced M68HC08 central processor unit (CPU08) and are available with a variety of modules, memory sizes and types, and package types.

#### 1.3 Features

Features of the MC68HC708MP16 include:

- High-performance M68HC08 architecture
- Fully upward-compatible object code with M6805, M146805, and M68HC05 Families
- 8-MHz internal bus frequency
- 16 Kbytes of on-chip erasable programmable read-only memory (EPROM) or one-time programmable read-only memory (OTPROM)
- On-chip programming firmware for use with host personal computer
- EPROM/OTPROM data security<sup>1</sup>
- 512 bytes of on-chip RAM
- 12-bit, 6-channel center-aligned or edge-aligned pulse width modulator (PWMMC)
- 64-pin plastic quad flat pack (QFP)
- Serial peripheral interface module (SPI)
- Serial communications interface module (SCI)
- 16-bit, 2-channel timer interface module (TIMA)
- 16-bit, 4-channel timer interface module (TIMB)

**Technical Data** 

<sup>1.</sup> No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the EPROM/OTPROM difficult for unauthorized users.

- Clock Generator module (CGM)
- Digitally filtered low-voltage inhibit (LVI45)
- 8-bit, 10-channel analog-to-digital convertor (ADC)
- System protection features:
  - Optional computer operating properly (COP) reset
  - Low-voltage detection with optional reset
  - Illegal opcode detection with optional reset
  - Illegal address detection with optional reset
  - Fault detection with optional PWM disabling
- Low-power design (fully static with wait mode)
- Master reset pin and power-on reset

#### Features of the CPU08 include:

- Enhanced HC05 programming model
- Extensive loop control functions
- 16 addressing modes (eight more than the HC05)
- 16-bit index register and stack pointer
- Memory-to-memory data transfers
- Fast 8 × 8 multiply instruction
- Fast 16/8 divide instruction
- Binary-coded decimal (BCD) instructions
- Optimization for controller applications
- C language support

#### 1.4 MCU Block Diagram

Figure 1-1 shows the structure of the MC68HC708MP16.

- Rev. 3.1

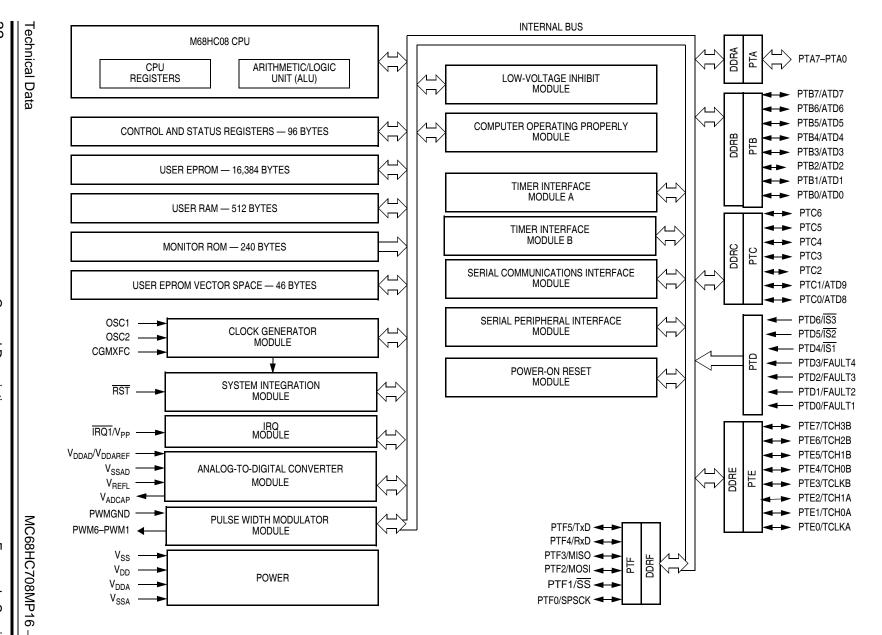

Figure 1-1. MCU Block Diagram

#### 1.5 Pin Assignments

Figure 1-2 shows the QFP pin assignments.

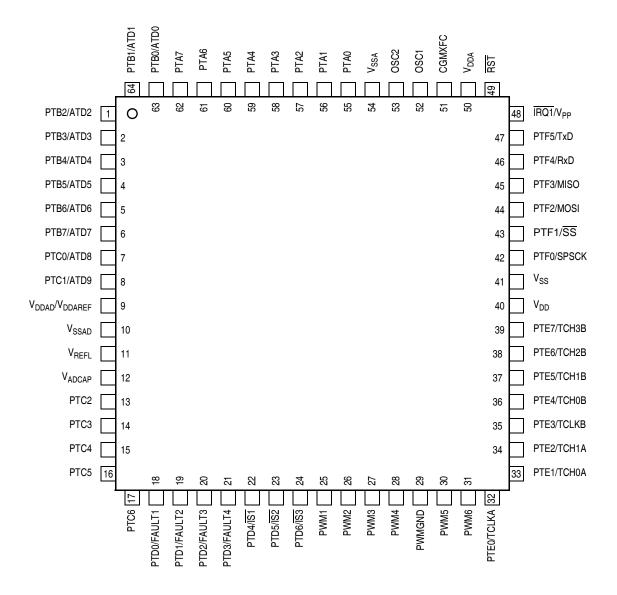

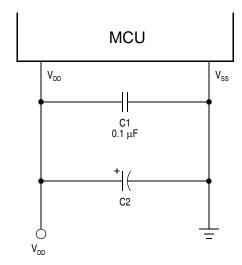

Figure 1-2. QFP Pin Assignments

MC68HC708MP16 - Rev. 3.1

#### 1.5.1 Power Supply Pins ( $V_{DD}$ and $V_{SS}$ )

 $V_{DD}$  and  $V_{SS}$  are the power supply and ground pins. The MCU operates from a single power supply.

Fast signal transitions on MCU pins place high, short-duration current demands on the power supply. To prevent noise problems, take special care to provide power supply bypassing at the MCU as **Figure 1-3** shows. Place the C1 bypass capacitor as close to the MCU as possible. Use a high-frequency-response ceramic capacitor for C1. C2 is an optional bulk current bypass capacitor for use in applications that require the port pins to source high current levels.

Note: Component values shown represent typical applications.

Figure 1-3. Power Supply Bypassing

#### 1.5.2 Oscillator Pins (OSC1 and OSC2)

The OSC1 and OSC2 pins are the connections for the on-chip oscillator circuit. (See Section 8. Clock Generator Module (CGM).)

#### 1.5.3 External Reset Pin (RST)

A logic 0 on the RST pin forces the MCU to a known start-up state. RST is bidirectional, allowing a reset of the entire system. It is driven low when

Technical Data MC68HC708MP16 — Rev. 3.1

any internal reset source is asserted. (See Section 7. System Integration Module (SIM).)

#### 1.5.4 External Interrupt Pin (IRQ1/V<sub>PP</sub>)

IRQ1/V<sub>PP</sub> is an asynchronous external interrupt pin. (See **Section 17**. **External Interrupt (IRQ)**.) IRQ1/V<sub>PP</sub> is also the EPROM/OTPROM programming power pin. (See **Section 2**. **Memory Map**.)

#### 1.5.5 CGM Power Supply Pins ( $V_{DDA}$ and $V_{SSA}$ )

 $V_{DDA}$  and  $V_{SSA}$  are the power supply pins for the analog portion of the clock generator module (CGM). Decoupling of these pins should be as per the digital supply. (See **Section 8. Clock Generator Module** (CGM).)

#### 1.5.6 External Filter Capacitor Pin (CGMXFC)

CGMXFC is an external filter capacitor connection for the CGM. (See Section 8. Clock Generator Module (CGM).)

#### 1.5.7 Analog Power Supply Pins ( $V_{DDAD}/V_{DDAREF}$ and $V_{SSAD}$ )

V<sub>DDAD</sub>/V<sub>DDAREF</sub> and V<sub>SSAD</sub> are the power supply pins for the analog-to-digital converter. Decoupling of these pins should be as per the digital supply. (See Section 19. Analog-to-Digital Converter (ADC).)

#### 1.5.8 ADC Voltage Decoupling Capacitor Pin (V<sub>ADCAP</sub>)

 $V_{ADCAP}$  is one of two reference supplies and is generated from  $V_{DDAREF}$  with a value ( $V_{DDAREF}$ )/2. Place a bypass capacitor on this pin to decouple noise. (See **Section 19. Analog-to-Digital Converter (ADC)**.)

MC68HC708MP16 — Rev. 3.1

#### 1.5.9 ADC Voltage Reference Low Pin (V<sub>REFL</sub>)

 $V_{REFL}$  is the lower reference supply for the ADC. Connect the  $V_{REFL}$  pin to the same voltage potential as  $V_{SSA}$ . (See **Section 19. Analog-to-Digital Converter (ADC)**.)

#### 1.5.10 Port A Input/Output (I/O) Pins (PTA7-PTA0)

PTA7–PTA0 are general-purpose bidirectional I/O port pins. (See Section 15. Input/Output (I/O) Ports.)

#### 1.5.11 Port B I/O Pins (PTB7/ATD7-PTB0/ATD0)

Port B is an 8-bit special function port that shares all eight pins with the analog-to-digital convertor (ADC). (See Section 19. Analog-to-Digital Converter (ADC) and Section 15. Input/Output (I/O) Ports.)

#### 1.5.12 Port C I/O Pins (PTC6-PTC2 and PTC1/ATD9-PTC0/ATD8)

PTC6—PTC2 are general-purpose bidirectional I/O port pins. (See Section 15. Input/Output (I/O) Ports.) PTC1/ATD9—PTC0/ATD8 are special function port pins that are shared with the analog-to-digital convertor (ADC). (See Section 19. Analog-to-Digital Converter (ADC) and Section 15. Input/Output (I/O) Ports.)

#### 1.5.13 Port D Input-Only Pins (PTD6/IS3-PTD4/IS1 and PTD3/FAULT4-PTD0/FAULT1)

PTD6/IS3—PTD4/IS1 are special function input-only port pins that also serve as current sensing pins for the pulse width modulator module (PWMMC). PTD3/FAULT4—PTD0/FAULT1 are special function port pins that also serve as fault pins for the pulse width modulator module (PWMMC). (See Section 9. Pulse Width Modulator for Motor Control (PWMMC) and Section 15. Input/Output (I/O) Ports.)

## 1.5.14 PWM Pins (PWM6-PWM1)

PWM6–PWM1 are dedicated pins used for the outputs of the pulse width modulator module (PWMMC). These are high current pins capable of 20 mA sink ( $V_{OL} = 0.8 \text{ V}$ ) and 7 mA ( $V_{OH} = V_{DD} - 0.8 \text{ V}$ ) source. (See Section 9. Pulse Width Modulator for Motor Control (PWMMC) and Section 21. Electrical Specifications.)

## 1.5.15 PWM Ground Pin (PWMGND)

PWMGND is the ground pin for the pulse width modulator module (PWMMC). This dedicated ground pin is used as the ground for the six high current PWM pins. (See Section 9. Pulse Width Modulator for Motor Control (PWMMC).)

## 1.5.16 Port E I/O Pins (PTE7/TCH3B-PTE3/TCLKB and PTE2/TCH1A-PTE0/TCLKA)

Port E is an 8-bit special function port that shares its pins with the two timer interface modules (TIMA and TIMB). (See Section 11. Timer Interface Module A (TIMA), Section 12. Timer Interface Module B (TIMB), and Section 15. Input/Output (I/O) Ports.)

### 1.5.17 Port F I/O Pins (PTF5/TxD-PTF4/RxD and PTF3/MISO-PTF0/SPSCK)

Port F is a 6-bit special function port that shares two of its pins with the serial communications interface module (SCI) and four of its pins with the serial peripheral interface module (SPI). (See Section 13. Serial Peripheral Interface Module (SPI), Section 14. Serial Communications Interface Module (SCI), and Section 15. Input/Output (I/O) Ports.)

2.4	Monitor ROM	.52

# 2.2 Introduction

The CPU08 can address 64 Kbytes of memory space. The memory map, shown in **Figure 2-1**, includes:

- 16 Kbytes of EPROM or OTPROM
- 512 bytes of RAM
- 46 bytes of user-defined vectors
- 240 bytes of monitor ROM

MC68HC708MP16 - Rev. 3.1

## 2.4 Monitor ROM

The 240 bytes at addresses \$FE10—\$FEFF are reserved ROM addresses that contain the instructions for the monitor functions. (See Section 10. Monitor ROM (MON).)

# Section 3. Random-Access Memory (RAM)

# 3.1 Contents

3.2	Introduction	53
3.3	Functional Description	53

## 3.2 Introduction

This section describes the 512 bytes of RAM.

# 3.3 Functional Description

Addresses \$0050–\$024F are RAM locations. The location of the stack RAM is programmable. The 16-bit stack pointer allows the stack to be anywhere in the 64-Kbyte memory space.

**NOTE:** For correct operation, the stack pointer must point only to RAM locations.

Within page zero are 160 bytes of RAM. Because the location of the stack RAM is programmable, all page zero RAM locations can be used for I/O control and user data or code. When the stack pointer is moved from its reset location at \$00FF, direct addressing mode instructions can access efficiently all page zero RAM locations. Page zero RAM, therefore, provides ideal locations for frequently accessed global variables.

Before processing an interrupt, the CPU uses five bytes of the stack to save the contents of the CPU registers.

**NOTE:** For M6805 compatibility, the H register is not stacked.

MC68HC708MP16 - Rev. 3.1

# Random-Access Memory (RAM)

During a subroutine call, the CPU uses two bytes of the stack to store the return address. The stack pointer decrements during pushes and increments during pulls.

NOTE:

Be careful when using nested subroutines. The CPU may overwrite data in the RAM during a subroutine or during the interrupt stacking operation.

# Section 4. EPROM/OTPROM

## 4.1 Contents

4.2	Introduction	.55
4.3	Functional Description	.55
4.4	EPROM/OTPROM Control Register	.56
4.5	EPROM/OTPROM Programming Sequence	.57

## 4.2 Introduction

This section describes the non-volatile memory (EPROM/OTPROM).

# 4.3 Functional Description

An MCU with a quartz window has 16 Kbytes of erasable, programmable ROM (EPROM). The quartz window allows EPROM erasure by using ultraviolet light. In an MCU without the quartz window, the EPROM cannot be erased and serves as 16 Kbytes of one-time programmable ROM (OTPROM). An unprogrammed or erased location reads as \$00. The following addresses are user EPROM/OTPROM locations:

- \$BE00-\$FDFF
- \$FFD2–\$FFFF (These locations are reserved for user-defined interrupt and reset vectors.)

Programming tools are available from Freescale. Contact your local Freescale representative for more information.

**NOTE:** A security feature prevents viewing of the EPROM/OTPROM contents.<sup>1</sup>

MC68HC708MP16 - Rev. 3.1

<sup>1.</sup> No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the EPROM/OTPROM difficult for unauthorized users.

# 4.4 EPROM/OTPROM Control Register

The EPROM control register controls EPROM/OTPROM programming.

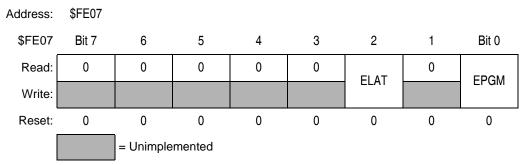

Figure 4-1. EPROM/OTPROM Control Register (EPMCR)

#### ELAT — EPROM/OTPROM Latch Control Bit

This read/write bit latches the address and data buses for programming the EPROM/OTPROM. Clearing ELAT also clears the EPGM bit. EPROM/OTPROM data cannot be read when ELAT is set.

- 1 = Buses configured for EPROM/OTPROM programming
- 0 = Buses configured for normal operation

### EPGM — EPROM/OTPROM Program Control Bit

This read/write bit applies the programming voltage from the IRQ1/V<sub>PP</sub> pin to the EPROM/OTPROM. To write to the EPGM bit, the ELAT bit must be set already. Reset clears the EPGM bit.

- 1 = EPROM/OTPROM programming power switched on
- 0 = EPROM/OTPROM programming power switched off

# 4.5 EPROM/OTPROM Programming Sequence

The unprogrammed state is a 0. Programming changes the state to a 1.

Use the following procedure to program a byte of EPROM/OTPROM:

- 1. Apply  $V_{DD} + V_{HI}$  to the  $\overline{IRQ1}/V_{PP}$  pin.
- 2. Set the ELAT bit.

**NOTE:** Writing logic 1s to both the ELAT and EPGM bits with a single instruction sets only the ELAT bit. EPGM must be set by a separate instruction in the programming sequence.

3. Write to any user EPROM/OTPROM address.

**NOTE:** Writing to an invalid address prevents the programming voltage from being applied.

- 4. Set the EPGM bit.
- 5. Wait for a time, t<sub>FPGM</sub>.
- 6. Clear the ELAT and EPGM bits.

Setting the ELAT bit configures the address and data buses to latch data for programming the array. Only data written to a valid EPROM address will be latched. Attempts to read any other valid EPROM address after step 2 will read the latched data written in step 3. Further writes to valid EPROM addresses after the first write (step 3) are ignored.

The EPGM bit cannot be set if ELAT bit is cleared. This is to ensure proper programming sequence. If EPGM is set and a valid EPROM write occurred, V<sub>PP</sub> will be applied to the user EPROM array. When the EPGM bit is cleared, the program voltage is removed from the array.

# EPROM/OTPROM

# Section 5. Configuration Register (CONFIG)

## 5.1 Contents

5.2	Introduction5	9
5.3	Functional Description	sC

## 5.2 Introduction

This section describes the configuration register (CONFIG). This register contains bits that configure the following options:

- Resets caused by the LVI module
- Power to the LVI module
- Computer operating properly module (COP)
- Top-side PWM polarity
- Bottom-side PWM polarity
- Edge-aligned versus center-aligned PWMs
- Six independent PWMs versus three complementary PWM pairs

# 5.3 Functional Description

The configuration register is a write-once register. Out of reset, the configuration register will read all 0s. Once the register is written, further writes will have no effect until a reset occurs.

#### **NOTE:**

If the LVI module and the LVI reset signal are enabled, a reset occurs when  $V_{DD}$  falls to a voltage, LVI<sub>TRIPF</sub>, and remains at or below that level for at least nine consecutive CPU cycles. Once an LVI reset occurs, the MCU remains in reset until  $V_{DD}$  rises to a voltage, LVI<sub>TRIPR</sub>.

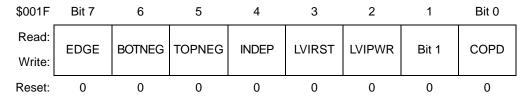

Figure 5-1. Configuration Register (CONFIG)

EDGE — Edge-Align Enable Bit

EDGE determines if the motor control PWM will operate in edgealigned mode or center-aligned mode. (See Section 9. Pulse Width Modulator for Motor Control (PWMMC).)

- 1 = Edge-aligned mode enabled
- 0 = Center-aligned mode enabled

BOTNEG — Bottom-Side PWM Polarity Bit

BOTNEG determines if the bottom-side PWMs will have positive or negative polarity. (See Section 9. Pulse Width Modulator for Motor Control (PWMMC).)

- 1 = Negative polarity
- 0 = Positive polarity

TOPNEG — Top-Side PWM Polarity Bit

TOPNEG determines if the top-side PWMs will have positive or negative polarity. (See Section 9. Pulse Width Modulator for Motor Control (PWMMC).)

- 1 = Negative polarity
- 0 = Positive polarity

INDEP — Independent Mode Enable Bit

INDEP determines if the motor control PWMs will be six independent PWMs or three complementary PWM pairs. (See Section 9. Pulse Width Modulator for Motor Control (PWMMC).)

1 = Six independent PWMs

0 = Three complementary PWM pairs

LVIPWR — LVI Power Disable Bit

LVIPWR disables the LVI module. (See **Section 18. Low-Voltage Inhibit (LVI)**.)

1 = LVI module power disabled

0 = LVI module power enabled

LVIRST — LVI Reset Disable Bit

LVIRST disables the reset signal from the LVI module. (See **Section 18. Low-Voltage Inhibit (LVI)**.)

1 = LVI module resets disabled

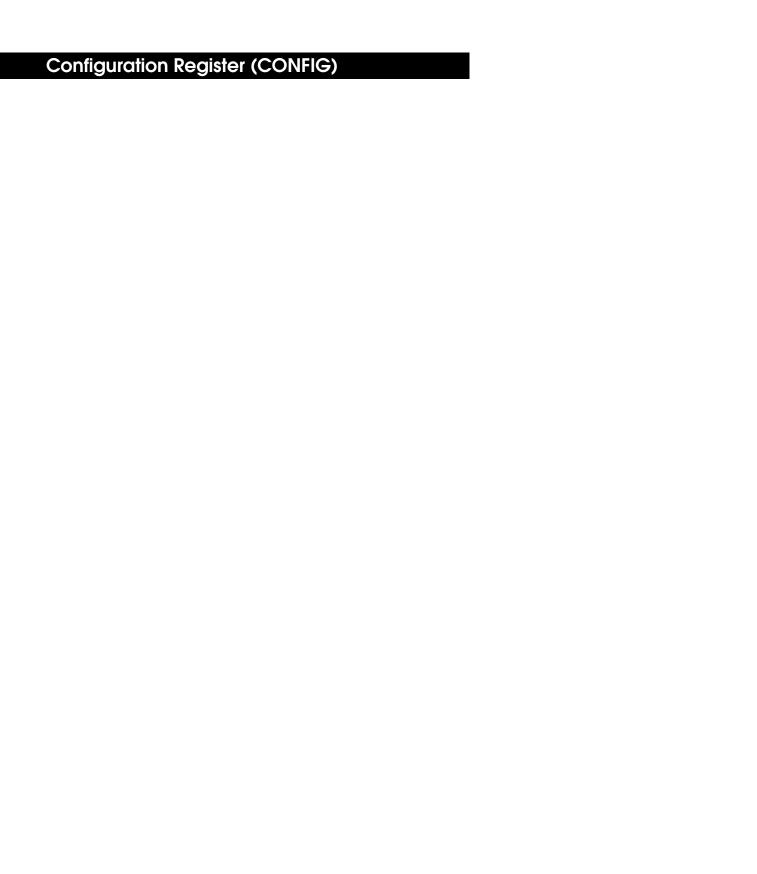

0 = LVI module resets enabled

COPD — COP Disable Bit

COPD disables the COP module. (See Section 16. Computer Operating Properly (COP).)

1 = COP module disabled

0 = COP module enabled

# Section 6. Central Processor Unit (CPU)

6.4.5	Condition Code Register (CCR)
6.5	Arithmetic/Logic Unit (ALU)71
6.6	Instruction Set Summary72
6.7	Opcode Map

## 6.2 Introduction

This section describes the central processor unit (CPU08, Version A). The M68HC08 CPU is an enhanced and fully object-code-compatible version of the M68HC05 CPU. The *CPU08 Reference Manual* (Freescale document number CPU08RM/AD) contains a description of the CPU instruction set, addressing modes, and architecture.

# **Central Processor Unit (CPU)**

## 6.3 Features

Features of the CPU include the following:

- Full upward, object-code compatibility with M68HC05 Family
- 16-bit stack pointer with stack manipulation instructions
- 16-bit index register with X-register manipulation instructions
- 8-MHz CPU internal bus frequency
- 64-Kbyte program/data memory space
- 16 addressing modes
- Memory-to-memory data moves without using accumulator
- Fast 8-bit by 8-bit multiply and 16-bit by 8-bit divide instructions
- Enhanced binary-coded decimal (BCD) data handling
- Modular architecture with expandable internal bus definition for extension of addressing range beyond 64 Kbytes
- Low-power wait mode

# 6.4 CPU Registers

**Figure 6-1** shows the five CPU registers. CPU registers are not part of the memory map.

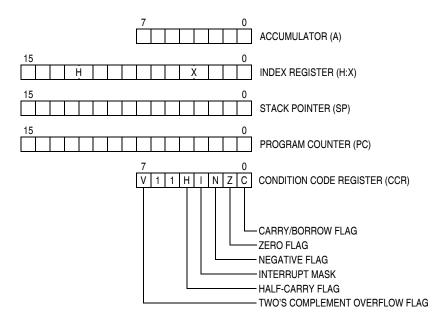

Figure 6-1. CPU Registers

## 6.4.1 Accumulator (A)

The accumulator is a general-purpose 8-bit register. The CPU uses the accumulator to hold operands and the results of arithmetic/logic operations.

Figure 6-2. Accumulator (A)

# **Central Processor Unit (CPU)**

## 6.4.2 Index Register (H:X)

The 16-bit index register allows indexed addressing of a 64-Kbyte memory space. H is the upper byte of the index register, and X is the lower byte. H:X is the concatenated 16-bit index register.

In the indexed addressing modes, the CPU uses the contents of the index register to determine the conditional address of the operand.

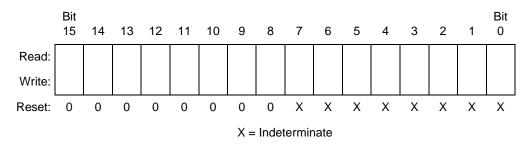

Figure 6-3. Index Register (H:X)

The index register can serve also as a temporary data storage location.

## 6.4.3 Stack Pointer (SP)

The stack pointer is a 16-bit register that contains the address of the next location on the stack. During a reset, the stack pointer is preset to \$00FF. The reset stack pointer (RSP) instruction sets the least significant byte to \$FF and does not affect the most significant byte. The stack pointer decrements as data is pushed onto the stack and increments as data is pulled from the stack.

In the stack pointer 8-bit offset and 16-bit offset addressing modes, the stack pointer can function as an index register to access data on the stack. The CPU uses the contents of the stack pointer to determine the conditional address of the operand.

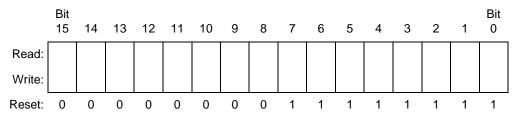

Figure 6-4. Stack Pointer (SP)

NOTE:

The location of the stack is arbitrary and may be relocated anywhere in RAM. Moving the SP out of page zero (\$0000 to \$00FF) frees direct address (page zero) space. For correct operation, the stack pointer must point only to RAM locations.

# **Central Processor Unit (CPU)**

## 6.4.4 Program Counter (PC)

The program counter is a 16-bit register that contains the address of the next instruction or operand to be fetched.

Normally, the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

During reset, the program counter is loaded with the reset vector address located at \$FFFE and \$FFFF. The vector address is the address of the first instruction to be executed after exiting the reset state.

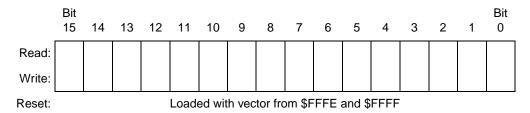

Figure 6-5. Program Counter (PC)

## 6.4.5 Condition Code Register (CCR)

The 8-bit condition code register contains the interrupt mask and five flags that indicate the results of the instruction just executed. Bits 6 and 5 are set permanently to logic one. The following paragraphs describe the functions of the condition code register.

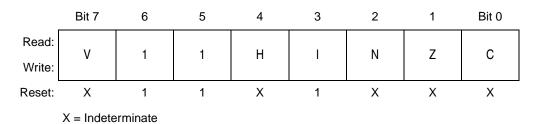

Figure 6-6. Condition Code Register (CCR)

### V — Overflow Flag

The CPU sets the overflow flag when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow flag.

1 = Overflow

0 = No overflow

### H — Half-Carry Flag

The CPU sets the half-carry flag when a carry occurs between accumulator bits 3 and 4 during an ADD or ADC operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations. The DAA instruction uses the states of the H and C flags to determine the appropriate correction factor.

1 = Carry between bits 3 and 4

0 = No carry between bits 3 and 4

# **Central Processor Unit (CPU)**

## I — Interrupt Mask

When the interrupt mask is set, all maskable CPU interrupts are disabled. CPU interrupts are enabled when the interrupt mask is cleared. When a CPU interrupt occurs, the interrupt mask is set automatically after the CPU registers are saved on the stack, but before the interrupt vector is fetched.

- 1 = Interrupts disabled
- 0 = Interrupts enabled

#### **NOTE:**

To maintain M6805 compatibility, the upper byte of the index register (H) is not stacked automatically. If the interrupt service routine modifies H, then the user must stack and unstack H using the PSHH and PULH instructions.

After the I bit is cleared, the highest-priority interrupt request is serviced first.

A return from interrupt (RTI) instruction pulls the CPU registers from the stack and restores the interrupt mask from the stack. After any reset, the interrupt mask is set and can only be cleared by the clear interrupt mask software instruction (CLI).

### N — Negative Flag

The CPU sets the negative flag when an arithmetic operation, logic operation, or data manipulation produces a negative result, setting bit 7 of the result.

- 1 = Negative result
- 0 = Non-negative result

#### Z — Zero Flag

The CPU sets the zero flag when an arithmetic operation, logic operation, or data manipulation produces a result of \$00.

- 1 = Zero result
- 0 = Non-zero result

# C — Carry/Borrow Flag

The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some instructions — such as bit test and branch, shift, and rotate — also clear or set the carry/borrow flag.

1 = Carry out of bit 7

0 = No carry out of bit 7

# 6.5 Arithmetic/Logic Unit (ALU)

The ALU performs the arithmetic and logic operations defined by the instruction set.

Refer to the *CPU08 Reference Manual* (Freescale document number CPU08RM/AD) for a description of the instructions and addressing modes and more detail about CPU architecture.

# 6.6 Instruction Set Summary

Table 6-1 provides a summary of the M68HC08 instruction set.

### 7.2 Introduction

This section describes the system integration module. Together with the CPU, the SIM controls all MCU activities. A block diagram of the SIM is shown in **Figure 7-1**. **Figure 7-1** is a summary of the SIM I/O registers. The SIM is a system state controller that coordinates CPU and exception timing. The SIM is responsible for:

- Bus clock generation and control for CPU and peripherals
  - Wait/reset/break entry and recovery
  - Internal clock control
- Master reset control, including power-on reset (POR) and COP timeout
- Interrupt control:
  - Acknowledge timing
  - Arbitration control timing
  - Vector address generation
- CPU enable/disable timing
- Modular architecture expandable to 128 interrupt sources

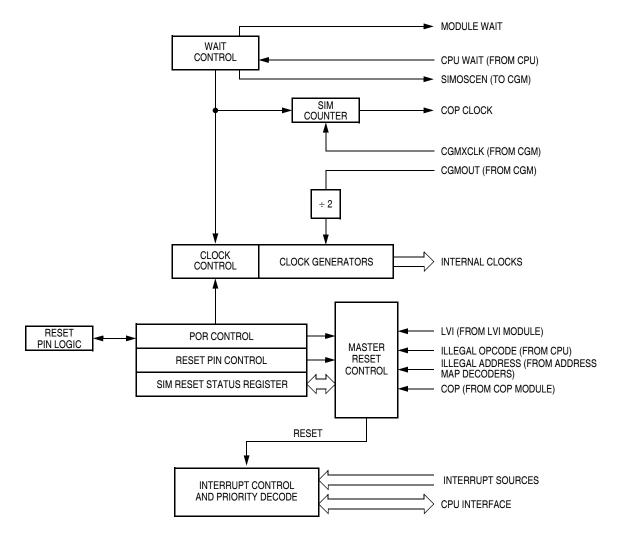

Figure 7-1. SIM Block Diagram

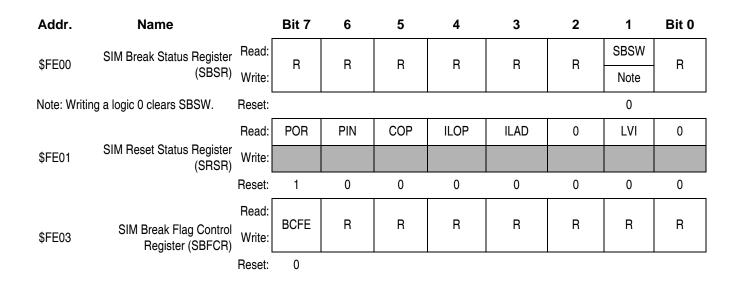

Figure 7-2. SIM I/O Register Summary

Table 7-1 shows the internal signal names used in this section.

**Table 7-1. Signal Name Conventions** 

Signal Name	Description
CGMXCLK	Buffered version of OSC1 from clock generator module (CGM)
CGMVCLK	PLL output
CGMOUT	PLL-based or OSC1-based clock output from CGM module (Bus clock = CGMOUT divided by two)
IAB	Internal address bus
IDB	Internal data bus
PORRST	Signal from the power-on reset module to the SIM
IRST	Internal reset signal
R/W	Read/write signal

## 7.3 SIM Bus Clock Control and Generation

The bus clock generator provides system clock signals for the CPU and peripherals on the MCU. The system clocks are generated from an incoming clock, CGMOUT, as shown in **Figure 7-3**. This clock can come from either an external oscillator or from the on-chip PLL. (See **Section 8. Clock Generator Module (CGM)**.)

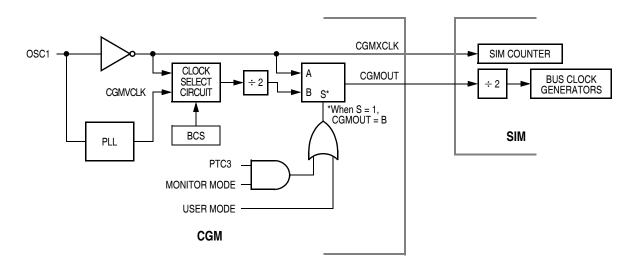

Figure 7-3. CGM Clock Signals

## 7.3.1 Bus Timing

In user mode, the internal bus frequency is either the crystal oscillator output (CGMXCLK) divided by four or the PLL output (CGMVCLK) divided by four. (See **Section 8. Clock Generator Module (CGM)**.)

## 7.3.2 Clock Start-Up from POR or LVI Reset

When the power-on reset module or the low-voltage inhibit module generates a reset, the clocks to the CPU and peripherals are inactive and held in an inactive phase until after the 4096 CGMXCLK cycle POR timeout has completed. The  $\overline{RST}$  pin is driven low by the SIM during this entire period. The IBUS clocks start upon completion of the timeout.

MC68HC708MP16 — Rev. 3.1

### 7.3.3 Clocks in Wait Mode

In wait mode, the CPU clocks are inactive. The SIM also produces two sets of clocks for other modules. Refer to the wait mode subsection of each module to see if the module is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

## 7.4 Reset and System Initialization

The MCU has the following reset sources:

- Power-on reset module (POR)
- External reset pin (RST)
- Computer operating properly module (COP)
- Low-voltage inhibit module (LVI)
- Illegal opcode
- Illegal address

All of these resets produce the vector \$FFFE–FFFF (\$FEFE–FEFF in monitor mode) and assert the internal reset signal (IRST). IRST causes all registers to be returned to their default values and all modules to be returned to their reset states.

An internal reset clears the SIM counter (see **7.5 SIM Counter**), but an external reset does not. Each of the resets sets a corresponding bit in the SIM reset status register (SRSR). (See **7.7.3 SIM Reset Status Register**.)

### 7.4.1 External Pin Reset

Pulling the asynchronous  $\overline{RST}$  pin low halts all processing. The PIN bit of the SIM reset status register (SRSR) is set as long as  $\overline{RST}$  is held low for a minimum of 67 CGMXCLK cycles, assuming that neither the POR nor the LVI was the source of the reset. See **Table 7-2** for details. **Figure 7-4** shows the relative timing.

**Table 7-2. PIN Bit Set Timing** 

Reset Type	Number of Cycles Required to Set PIN
POR/LVI	4163 (4096 + 64 + 3)
All Others	67 (64 + 3)

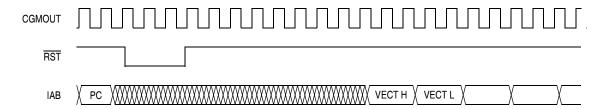

Figure 7-4. External Reset Timing

### 7.4.2 Active Resets from Internal Sources

All internal reset sources actively pull the  $\overline{RST}$  pin low for 32 CGMXCLK cycles to allow resetting of external peripherals. The internal reset signal IRST continues to be asserted for an additional 32 cycles. (See Figure 7-5.) An internal reset can be caused by an illegal address, illegal opcode, COP timeout, LVI, or POR. (See Figure 7-6.) Note that for LVI or POR resets, the SIM cycles through 4096 CGMXCLK cycles during which the SIM forces the  $\overline{RST}$  pin low. The internal reset signal then follows the sequence from the falling edge of  $\overline{RST}$  shown in Figure 7-5.

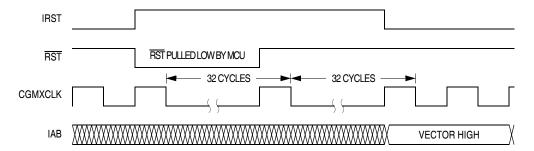

Figure 7-5. Internal Reset Timing

The COP reset is asynchronous to the bus clock.

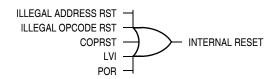

Figure 7-6. Sources of Internal Reset

The active reset feature allows the part to issue a reset to peripherals and other chips within a system built around the MCU.

#### 7.4.2.1 Power-On Reset

When power is first applied to the MCU, the power-on reset module (POR) generates a pulse to indicate that power-on has occurred. The external reset pin (RST) is held low while the SIM counter counts out 4096 CGMXCLK cycles. Sixty-four CGMXCLK cycles later, the CPU and memories are released from reset to allow the reset vector sequence to occur.

At power-on, the following events occur:

- A POR pulse is generated.
- The internal reset signal is asserted.
- The SIM enables CGMOUT.
- Internal clocks to the CPU and modules are held inactive for 4096 CGMXCLK cycles to allow stabilization of the oscillator.
- The RST pin is driven low during the oscillator stabilization time.
- The POR bit of the SIM reset status register (SRSR) is set and all other bits in the register are cleared.

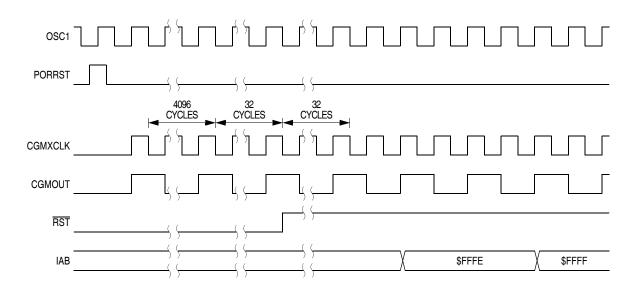

Figure 7-7. POR Recovery

MC68HC708MP16 — Rev. 3.1

## 7.4.2.2 Computer Operating Properly (COP) Reset

An input to the SIM is reserved for the COP reset signal. The overflow of the COP counter causes an internal reset and sets the COP bit in the SIM reset status register (SRSR). The SIM actively pulls down the RST pin for all internal reset sources.

To prevent a COP module timeout, write any value to location \$FFFF. Writing to location \$FFFF clears the COP counter and bits 12 through 4 of the SIM counter. The SIM counter output, which occurs at least every  $2^{13} - 2^4$  CGMXCLK cycles, drives the COP counter. The COP should be serviced as soon as possible out of reset to guarantee the maximum amount of time before the first timeout.

The COP module is disabled if the  $\overline{RST}$  pin or the  $\overline{IRQ1}/V_{PP}$  pin is held at  $V_{DD}$  +  $V_{HI}$  while the MCU is in monitor mode. The COP module can be disabled only through combinational logic conditioned with the high voltage signal on the  $\overline{RST}$  or the  $\overline{IRQ1}/V_{PP}$  pin. This prevents the COP from becoming disabled as a result of external noise. During a break state,  $V_{DD}$  +  $V_{HI}$  on the  $\overline{RST}$  pin disables the COP module.

## 7.4.2.3 Illegal Opcode Reset

The SIM decodes signals from the CPU to detect illegal instructions. An illegal instruction sets the ILOP bit in the SIM reset status register (SRSR) and causes a reset.

Because the MC68HC708MP16 has stop mode disabled, execution of the STOP instruction will cause an illegal opcode reset.

## 7.4.2.4 Illegal Address Reset

An opcode fetch from addresses other than EPROM or RAM addresses generates an illegal address reset. The SIM verifies that the CPU is fetching an opcode prior to asserting the ILAD bit in the SIM reset status register (SRSR) and resetting the MCU. A data fetch from an unmapped address does not generate a reset.

## 7.4.2.5 Low-Voltage Inhibit (LVI) Reset

The low-voltage inhibit module (LVI) asserts its output to the SIM when the  $V_{DD}$  voltage falls to the  $LVI_{TRIPF}$  voltage and remains at or below that level for at least nine consecutive CPU cycles. The LVI bit in the SIM reset status register (SRSR) is set, and the external reset pin ( $\overline{RST}$ ) is held low while the SIM counter counts out 4096 CGMXCLK cycles. Sixty-four CGMXCLK cycles later, the CPU is released from reset to allow the reset vector sequence to occur. The SIM actively pulls down the  $\overline{RST}$  pin for all internal reset sources.

### 7.5 SIM Counter

The SIM counter is used by the power-on reset module (POR) to allow the oscillator time to stabilize before enabling the internal bus (IBUS) clocks. The SIM counter also serves as a prescaler for the computer operating properly module (COP). The SIM counter overflow supplies the clock for the COP module. The SIM counter is 13 bits long and is clocked by the falling edge of CGMXCLK.

## 7.5.1 SIM Counter During Power-On Reset

The power-on reset module (POR) detects power applied to the MCU. At power-on, the POR circuit asserts the signal PORRST. Once the SIM is initialized, it enables the clock generation module (CGM) to drive the bus clock state machine.

#### 7.5.2 SIM Counter and Reset States

External reset has no effect on the SIM counter. The SIM counter is freerunning after all reset states. (See **7.4.2 Active Resets from Internal Sources** for counter control and internal reset recovery sequences.)

MC68HC708MP16 — Rev. 3.1

## 7.6 Exception Control

Normal, sequential program execution can be changed in three different ways:

- Interrupts
  - Maskable hardware CPU interrupts
  - Non-maskable software interrupt instruction (SWI)
- Reset
- · Break interrupts

## 7.6.1 Interrupts

At the beginning of an interrupt, the CPU saves the CPU register contents on the stack and sets the interrupt mask (I bit) to prevent additional interrupts. At the end of an interrupt, the RTI instruction recovers the CPU register contents from the stack so that normal processing can resume. Figure 7-8 shows interrupt entry timing. Figure 7-10 shows interrupt recovery timing.

Interrupts are latched, and arbitration is performed in the SIM at the start of interrupt processing. The arbitration result is a constant that the CPU uses to determine which vector to fetch. Once an interrupt is latched by the SIM, no other interrupt can take precedence, regardless of priority, until the latched interrupt is serviced (or the I bit is cleared). (See Figure 7-9.)

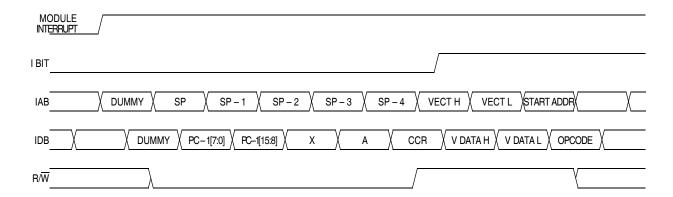

Figure 7-8. Interrupt Entry

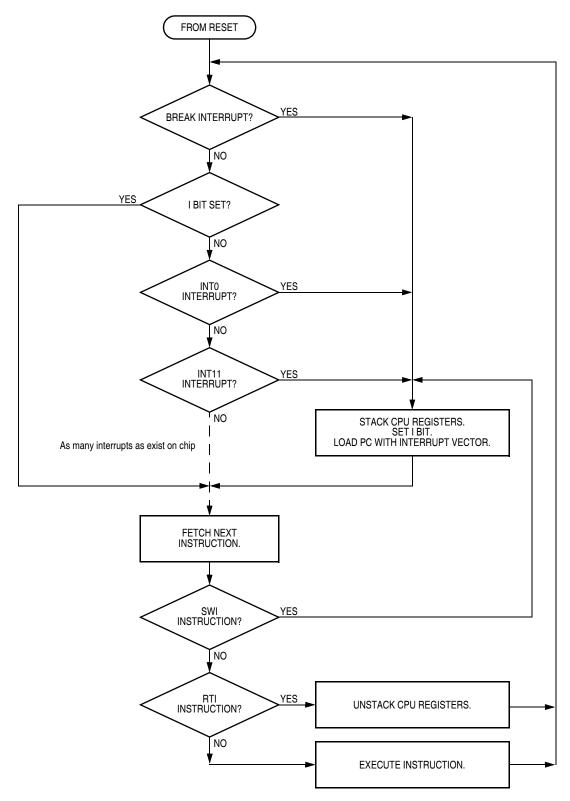

Figure 7-9. Interrupt Processing

MC68HC708MP16 - Rev. 3.1

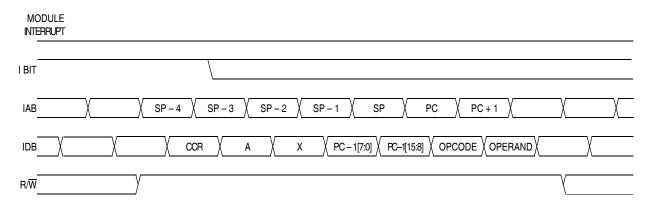

Figure 7-10. Interrupt Recovery

## 7.6.1.1 Hardware Interrupts

A hardware interrupt does not stop the current instruction. Processing of a hardware interrupt begins after completion of the current instruction. When the current instruction is complete, the SIM checks all pending hardware interrupts. If interrupts are not masked (I bit clear in the condition code register), and if the corresponding interrupt enable bit is set, the SIM proceeds with interrupt processing; otherwise, the next instruction is fetched and executed.

If more than one interrupt is pending at the end of an instruction execution, the highest priority interrupt is serviced first. Figure 7-11 demonstrates what happens when two interrupts are pending. If an interrupt is pending upon exit from the original interrupt service routine, the pending interrupt is serviced before the LDA instruction is executed.

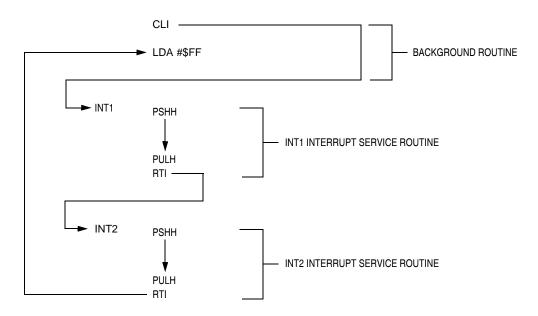

Figure 7-11. Interrupt Recognition Example

The LDA opcode is prefetched by both the INT1 and INT2 RTI instructions. However, in the case of the INT1 RTI prefetch, this is a redundant operation.

#### NOTE:

To maintain compatibility with the M6805 Family, the H register is not pushed on the stack during interrupt entry. If the interrupt service routine modifies the H register or uses the indexed addressing mode, software should save the H register and then restore it prior to exiting the routine.

#### 7.6.1.2 SWI Instruction

The SWI instruction is a non-maskable instruction that causes an interrupt regardless of the state of the interrupt mask (I bit) in the condition code register.

#### **NOTE:**

A software interrupt pushes PC onto the stack. A software interrupt does not push PC - 1, as a hardware interrupt does.

#### 7.6.2 **Reset**

All reset sources always have equal and highest priority and cannot be arbitrated.

## 7.6.3 Status Flag Protection in Break Mode

The SIM controls whether status flags contained in other modules can be cleared during break mode. The user can select whether flags are protected from being cleared by properly initializing the break clear flag enable bit (BCFE) in the SIM break flag control register (SBFCR).

Protecting flags in break mode ensures that set flags will not be cleared while in break mode. This protection allows registers to be freely read and written during break mode without losing status flag information.

Setting the BCFE bit enables the clearing mechanisms. Once cleared in break mode, a flag remains cleared even when break mode is exited. Status flags with a two-step clearing mechanism — for example, a read of one register followed by the read or write of another — are protected, even when the first step is accomplished prior to entering break mode. Upon leaving break mode, execution of the second step will clear the flag as normal.

#### 7.7 Low-Power Mode

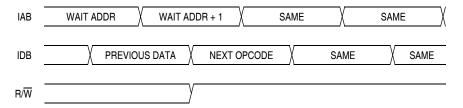

Executing the WAIT instruction puts the MCU in a low-power-consumption mode for standby situations. The SIM holds the CPU in a non-clocked state. The operation of this mode is described below. WAIT clears the interrupt mask (I) in the condition code register, allowing interrupts to occur.

#### 7.7.1 Wait Mode

In wait mode, the CPU clocks are inactive while the peripheral clocks continue to run. **Figure 7-12** shows the timing for wait mode entry.

A module that is active during wait mode can wake up the CPU with an interrupt if the interrupt is enabled. Stacking for the interrupt begins one cycle after the WAIT instruction during which the interrupt occurred. Refer to the wait mode subsection of each module to see if the module is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

Wait mode can also be exited by a reset or break. A break interrupt during wait mode sets the SIM break stop/wait bit, SBSW, in the SIM break status register (SBSR). If the COP disable bit, COPD, in the configuration register is logic 0, then the computer operating properly module (COP) is enabled and remains active in wait mode.

NOTE: Previous data can be operand data or the WAIT opcode, depending on the last instruction.

Figure 7-12. Wait Mode Entry Timing

Figure 7-13 and Figure 7-14 show the timing for WAIT recovery.

NOTE: EXITSTOPWAIT =  $\overline{RST}$  pin OR CPU interrupt OR break interrupt

Figure 7-13. Wait Recovery from Interrupt or Break

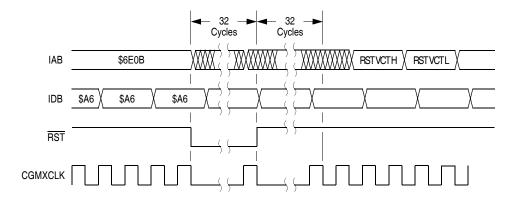

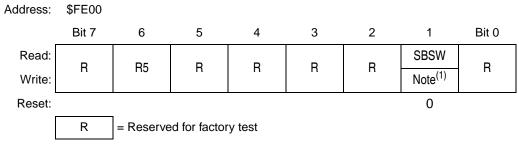

Figure 7-14. Wait Recovery from Internal Reset

## 7.7.2 SIM Break Status Register

The SIM break status register contains a flag to indicate that a break caused an exit from wait mode.

NOTE 1. Writing a logic 0 clears SBSW.

Figure 7-15. SIM Break Status Register (SBSR)

#### SBSW — SIM Break Stop/Wait

This status bit is useful in applications requiring a return to wait mode after exiting from a break interrupt. Clear SBSW by writing a logic 0 to it. Reset clears SBSW.

- 1 = Wait mode was exited by break interrupt.
- 0 = Wait mode was not exited by break interrupt.

SBSW can be read within the break state SWI routine. The user can modify the return address on the stack by subtracting one from it. The following code is an example of this. Writing zero to the SBSW bit clears it.

```
; This code works if the H register has been pushed onto the stack in the break
; service routine software. This code should be executed at the end of the break
; service routine software.
 HIBYTE
        EQU
 LOBYTE EQU
          If not SBSW, do RTI
          BRCLR SBSW, SBSR, RETURN ; See if wait mode was exited by break.

```

## 7.7.3 SIM Reset Status Register

This register contains six flags that show the source of the last reset. Clear the SIM reset status register by reading it. A power-on reset sets the POR bit and clears all other bits in the register.

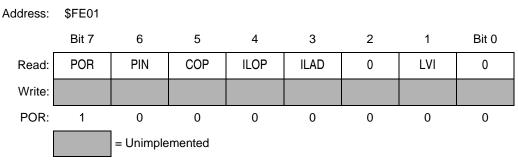

Figure 7-16. SIM Reset Status Register (SRSR)

POR — Power-On Reset Bit

1 = Last reset caused by POR circuit

0 = Read of SRSR

PIN — External Reset Bit

1 = Last reset caused by external reset pin (RST)

0 = POR or read of SRSR

COP — Computer Operating Properly Reset Bit

1 = Last reset caused by COP counter

0 = POR or read of SRSR

ILOP — Illegal Opcode Reset Bit

1 = Last reset caused by an illegal opcode

0 = POR or read of SRSR

ILAD — Illegal Address Reset Bit (opcode fetches only)

1 = Last reset caused by an opcode fetch from an illegal address

0 = POR or read of SRSR

LVI — Low-Voltage Inhibit Reset Bit

1 = Last reset was caused by the LVI circuit

0 = POR or read of SRSR

## 7.7.4 SIM Break Flag Control Register

The SIM break control register contains a bit that enables software to clear status bits while the MCU is in a break state.

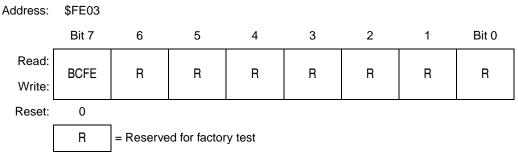

Figure 7-17. SIM Break Flag Control Register (SBFCR)

### BCFE — Break Clear Flag Enable Bit

This read/write bit enables software to clear status bits by accessing status registers while the MCU is in a break state. To clear status bits during the break state, the BCFE bit must be set.

- 1 = Status bits clearable during break
- 0 = Status bits not clearable during break

### 8.2 Introduction

This section describes the clock generator module (CGM, Version A). The CGM generates the crystal clock signal, CGMXCLK, which operates at the frequency of the crystal. The CGM also generates the base clock signal, CGMOUT, from which the system integration module (SIM) derives the system clocks. CGMOUT is based on either the crystal clock divided by two or the phase-locked loop (PLL) clock, CGMVCLK, divided by two. The PLL is a frequency generator designed for use with crystals or ceramic resonators. The PLL can generate an 8-MHz bus frequency without using a 32-MHz crystal.

## 8.3 Features

Features of the CGM include the following:

- Phase-locked loop with output frequency in integer multiples of the crystal reference
- Programmable hardware voltage-controlled oscillator (VCO) for low-jitter operation
- Automatic bandwidth control mode for low-jitter operation
- Automatic frequency lock detector
- CPU interrupt on entry or exit from locked condition

## 8.4 Functional Description

The CGM consists of three major submodules:

- Crystal oscillator circuit The crystal oscillator circuit generates the constant crystal frequency clock, CGMXCLK.
- Phase-locked loop (PLL) The PLL generates the programmable VCO frequency clock CGMVCLK.
- Base clock selector circuit This software-controlled circuit selects either CGMXCLK divided by two or the VCO clock, CGMVCLK, divided by two as the base clock, CGMOUT. The SIM derives the system clocks from CGMOUT.

Figure 8-1 shows the structure of the CGM.

## 8.4.1 Crystal Oscillator Circuit

The crystal oscillator circuit consists of an inverting amplifier and an external crystal. The OSC1 pin is the input to the amplifier and the OSC2 pin is the output. The SIMOSCEN signal from the system integration module (SIM) enables the crystal oscillator circuit.

The CGMXCLK signal is the output of the crystal oscillator circuit and runs at a rate equal to the crystal frequency. CGMXCLK is then buffered to produce CGMRCLK, the PLL reference clock.

CGMXCLK can be used by other modules which require precise timing for operation. The duty cycle of CGMXCLK is not guaranteed to be 50% and depends on external factors, including the crystal and related external components.

An externally generated clock also can feed the OSC1 pin of the crystal oscillator circuit. Connect the external clock to the OSC1 pin and let the OSC2 pin float.

## Clock Generator Module (CGM)

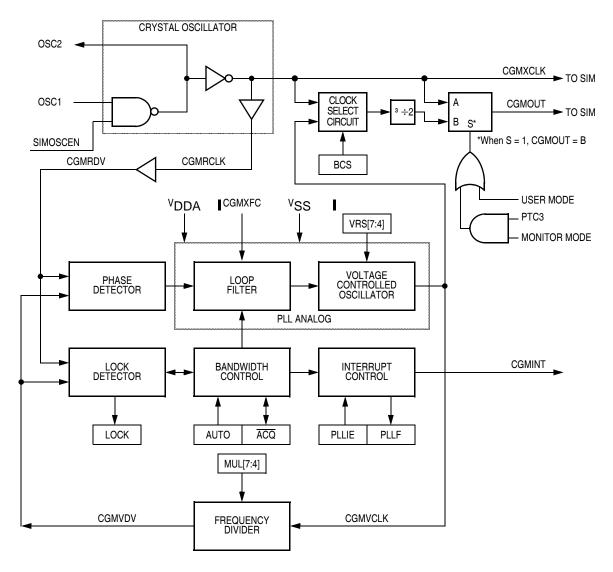

Figure 8-1. CGM Block Diagram

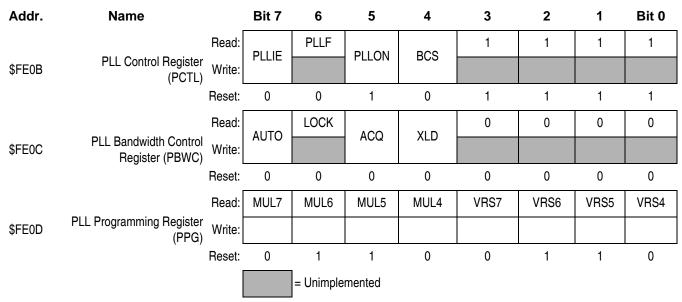

Figure 8-2. CGM I/O Register Summary

## 8.4.2 Phase-Locked Loop Circuit (PLL)

The PLL is a frequency generator that can operate in either acquisition mode or tracking mode, depending on the accuracy of the output frequency. The PLL can change between acquisition and tracking modes either automatically or manually.

#### 8.4.2.1 PLL Circuits

The PLL consists of the following circuits:

- Voltage-controlled oscillator (VCO)
- Modulo VCO frequency divider
- Phase detector
- Loop filter
- Lock detector

## **Clock Generator Module (CGM)**

The operating range of the VCO is programmable for a wide range of frequencies and for maximum immunity to external noise, including supply and CGMXFC noise. The VCO frequency is bound to a range from roughly one-half to twice the center-of-range frequency,  $f_{VRS}$ . Modulating the voltage on the CGMXFC pin changes the frequency within this range. By design,  $f_{VRS}$  is equal to the nominal center-of-range frequency,  $f_{NOM}$ , (4.9152 MHz) times a linear factor L, or (L) $f_{NOM}$ .

CGMRCLK is the PLL reference clock, a buffered version of CGMXCLK. CGMRCLK runs at a frequency,  $f_{RCLK}$ , and is fed to the PLL through a buffer. The buffer output is the final reference clock, CGMRDV, running at a frequency  $f_{RDV} = f_{RCLK}$ .

The VCO's output clock, CGMVCLK, running at a frequency  $f_{VCLK}$ , is fed back through a programmable modulo divider. The modulo divider reduces the VCO clock by a factor, N. The dividers output is the VCO feedback clock, CGMVDV, running at a frequency  $f_{VDV} = f_{VCLK}/N$ . (See **8.4.2.4 Programming the PLL** for more information.)

The phase detector then compares the VCO feedback clock, CGMVDV, with the final reference clock, CGMRDV. A correction pulse is generated based on the phase difference between the two signals. The loop filter then slightly alters the DC voltage on the external capacitor connected to CGMXFC based on the width and direction of the correction pulse. The filter can make fast or slow corrections depending on its mode, described in 8.4.2.2 Acquisition and Tracking Modes. The value of the external capacitor and the reference frequency determines the speed of the corrections and the stability of the PLL.

The lock detector compares the frequencies of the VCO feedback clock, CGMVDV, and the final reference clock, CGMRDV. Therefore, the speed of the lock detector is directly proportional to the final reference frequency  $f_{RDV}$ . The circuit determines the mode of the PLL and the lock condition based on this comparison.

#### 8.4.2.2 Acquisition and Tracking Modes

The PLL filter is manually or automatically configurable into one of two operating modes:

- Acquisition mode In acquisition mode, the filter can make large frequency corrections to the VCO. This mode is used at PLL start-up or when the PLL has suffered a severe noise hit and the VCO frequency is far off the desired frequency. When in acquisition mode, the ACQ bit is clear in the PLL bandwidth control register. (See 8.6.2 PLL Bandwidth Control Register.)
- Tracking mode In tracking mode, the filter makes only small corrections to the frequency of the VCO. PLL jitter is much lower in tracking mode, but the response to noise is also slower. The PLL enters tracking mode when the VCO frequency is nearly correct, such as when the PLL is selected as the base clock source. (See 8.4.3 Base Clock Selector Circuit.) The PLL is automatically in tracking mode when not in acquisition mode or when the ACQ bit is set.

#### 8.4.2.3 Manual and Automatic PLL Bandwidth Modes

The PLL can change the bandwidth or operational mode of the loop filter manually or automatically.

In automatic bandwidth control mode (AUTO = 1), the lock detector automatically switches between acquisition and tracking modes. Automatic bandwidth control mode also is used to determine when the VCO clock, CGMVCLK, is safe to use as the source for the base clock, CGMOUT. (See 8.6.2 PLL Bandwidth Control Register.) If PLL interrupts are enabled, the software can wait for a PLL interrupt request and then check the LOCK bit. If interrupts are disabled, software can poll the LOCK bit continuously (during PLL start-up, usually) or at periodic intervals. In either case, when the LOCK bit is set, the VCO clock is safe to use as the source for the base clock. (See 8.4.3 Base Clock Selector Circuit.) If the VCO is selected as the source for the base clock and the LOCK bit is clear, the PLL has suffered a severe noise hit and the software must take appropriate action, depending on the application. (See 8.7 Interrupts for information and precautions on using interrupts.)

MC68HC708MP16 — Rev. 3.1

## **Clock Generator Module (CGM)**

The following conditions apply when the PLL is in automatic bandwidth control mode:

- The ACQ bit (see 8.6.2 PLL Bandwidth Control Register) is a read-only indicator of the mode of the filter. (See 8.4.2.2 Acquisition and Tracking Modes.)
- The ACQ bit is set when the VCO frequency is within a certain tolerance, Δ<sub>TRK</sub>, and is cleared when the VCO frequency is out of a certain tolerance, Δ<sub>UNT</sub>. (See 8.10 Acquisition/Lock Time Specifications for more information.)
- The LOCK bit is a read-only indicator of the locked state of the PLL.
- The LOCK bit is set when the VCO frequency is within a certain tolerance, Δ<sub>LOCK</sub>, and is cleared when the VCO frequency is out of a certain tolerance, Δ<sub>UNL</sub>. (See 8.10 Acquisition/Lock Time Specifications for more information.)
- CPU interrupts can occur if enabled (PLLIE = 1) when the PLL's lock condition changes, toggling the LOCK bit. (See 8.6.1 PLL Control Register.)

The PLL also may operate in manual mode (AUTO = 0). Manual mode is used by systems that do not require an indicator of the lock condition for proper operation. Such systems typically operate well below  $f_{BUSMAX}$  and require fast start-up. The following conditions apply when in manual mode:

- ACQ is a writable control bit that controls the mode of the filter.
   Before turning on the PLL in manual mode, the ACQ bit must be clear.
- Before entering tracking mode (ACQ = 1), software must wait a given time, t<sub>ACQ</sub> (see 8.10 Acquisition/Lock Time Specifications), after turning on the PLL by setting PLLON in the PLL control register (PCTL).
- Software must wait a given time, t<sub>AL</sub>, after entering tracking mode before selecting the PLL as the clock source to CGMOUT (BCS = 1).
- The LOCK bit is disabled.
- CPU interrupts from the CGM are disabled.

#### 8.4.2.4 Programming the PLL

The following procedure shows how to program the PLL.

**NOTE:** The round function in the following equations means that the real number should be rounded to the nearest integer number.

- 1. Choose the desired bus frequency, f<sub>BUSDES</sub>.
- 2. Calculate the desired VCO frequency (four times the desired bus frequency).

$$f_{VCLKDES} = 4 \times f_{BUSDES}$$

- 3. Choose a practical PLL reference frequency, f<sub>RCLK</sub>.
- 4. Select a VCO frequency multiplier, N.

$$N = round \left( \frac{f_{VCLKDES}}{f_{RCLK}} \right)$$

5. Calculate and verify the adequacy of the VCO and bus frequencies f<sub>VCLK</sub> and f<sub>BUS</sub>.

$$f_{VCLK} = N \times f_{RCLK}$$

$$f_{BUS} = (f_{VCLK})/4$$

6. Select a VCO linear range multiplier, L.

$$L = round \left( \frac{f_{VCLK}}{f_{NOM}} \right)$$

where 
$$f_{NOM} = 4.9152 \text{ MHz}$$

7. Calculate and verify the adequacy of the VCO programmed center-of-range frequency f<sub>VRS</sub>.

$$f_{VRS} = (L)f_{NOM}$$

8. Verify the choice of N and L by comparing  $f_{VCLK}$  to  $f_{VRS}$  and  $f_{VCLKDES}$ . For proper operation,  $f_{VCLK}$  must be within the application's tolerance of  $f_{VCLKDES}$ , and  $f_{VRS}$  must be as close as possible to  $f_{VCLK}$ .

MC68HC708MP16 — Rev. 3.1

## **Clock Generator Module (CGM)**

**NOTE:** Exceeding the recommended maximum bus frequency or VCO frequency can crash the MCU.

- 9. Program the PLL registers accordingly:
  - In the upper four bits of the PLL programming register (PPG), program the binary equivalent of N.
  - b. In the lower four bits of the PLL programming register (PPG), program the binary equivalent of L.

#### 8.4.2.5 Special Programming Exceptions

The programming method described in **8.4.2.4 Programming the PLL** does not account for possible exceptions. A value of zero for N or L is meaningless when used in the equations given. To account for these exceptions:

- A zero value for N is interpreted exactly the same as a value of one.
- A zero value for L disables the PLL and prevents its selection as the source for the base clock. (See 8.4.3 Base Clock Selector Circuit.)

#### 8.4.3 Base Clock Selector Circuit

This circuit is used to select either the crystal clock, CGMXCLK, or the VCO clock, CGMVCLK, as the source of the base clock, CGMOUT. The two input clocks go through a transition control circuit that waits up to three CGMXCLK cycles and three CGMVCLK cycles to change from one clock source to the other. During this time, CGMOUT is held in stasis. The output of the transition control circuit is then divided by two to correct the duty cycle. Therefore, the bus clock frequency, which is one-half of the base clock frequency, is one-fourth the frequency of the selected clock (CGMXCLK or CGMVCLK).

The BCS bit in the PLL control register (PCTL) selects which clock drives CGMOUT. The VCO clock cannot be selected as the base clock source if the PLL is not turned on. The PLL cannot be turned off if the VCO clock is selected. The PLL cannot be turned on or off simultaneously with the

selection or deselection of the VCO clock. The VCO clock also cannot be selected as the base clock source if the factor L is programmed to a zero. This value would set up a condition inconsistent with the operation of the PLL, so that the PLL would be disabled and the crystal clock would be forced as the source of the base clock.

#### 8.4.4 CGM External Connections

In its typical configuration, the CGM requires seven external components. Five of these are for the crystal oscillator and two are for the PLL.

The crystal oscillator is normally connected in a Pierce oscillator configuration, as shown in **Figure 8-3**. **Figure 8-3** shows only the logical representation of the internal components and may not represent actual circuitry. The oscillator configuration uses five components:

- Crystal, X<sub>1</sub>
- Fixed capacitor, C<sub>1</sub>
- Tuning capacitor, C<sub>2</sub> (can also be a fixed capacitor)
- Feedback resistor, R<sub>R</sub>
- Series resistor, R<sub>S</sub> (optional)

The series resistor ( $R_S$ ) is included in the diagram to follow strict Pierce oscillator guidelines and may not be required for all ranges of operation, especially with high frequency crystals. Refer to the crystal manufacturer's data for more information.

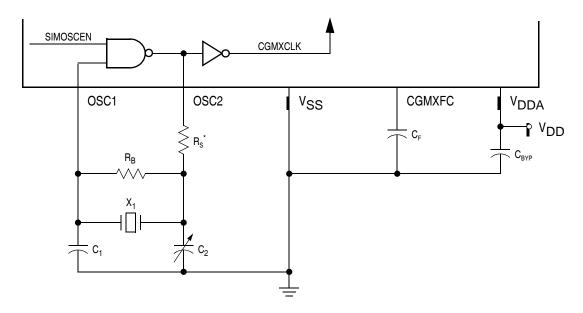

Figure 8-3 also shows the external components for the PLL:

- Bypass capacitor, C<sub>BYP</sub>
- Filter capacitor, C<sub>F</sub>

Routing should be done with great care to minimize signal cross talk and noise. (See **8.10 Acquisition/Lock Time Specifications** for routing information and more information on the filter capacitor's value and its effects on PLL performance.)

MC68HC708MP16 — Rev. 3.1

## **Clock Generator Module (CGM)**

<sup>\*</sup>R<sub>s</sub> can be zero (shorted) when used with higher-frequency crystals. Refer to manufacturer's data.

Figure 8-3. CGM External Connections

## 8.5 I/O Signals

The following paragraphs describe the CGM I/O signals.

## 8.5.1 Crystal Amplifier Input Pin (OSC1)

The OSC1 pin is an input to the crystal oscillator amplifier.

## 8.5.2 Crystal Amplifier Output Pin (OSC2)

The OSC2 pin is the output of the crystal oscillator inverting amplifier.

## 8.5.3 External Filter Capacitor Pin (CGMXFC)

The CGMXFC pin is required by the loop filter to filter out phase corrections. A small external capacitor is connected to this pin.

**NOTE:** 

To prevent noise problems,  $C_F$  should be placed as close to the CGMXFC pin as possible, with minimum routing distances and no routing of other signals across the  $C_F$  connection.

### 8.5.4 PLL Analog Power Pin (V<sub>DDA</sub>)

 $V_{DDA}$  is a power pin used by the analog portions of the PLL. Connect the  $V_{DDA}$  pin to the same voltage potential as the  $V_{DD}$  pin.

NOTE:

Route  $V_{\text{DDA}}$  carefully for maximum noise immunity and place bypass capacitors as close as possible to the package.

#### 8.5.5 Oscillator Enable Signal (SIMOSCEN)

The SIMOSCEN signal comes from the system integration module (SIM) and enables the oscillator and PLL.

#### 8.5.6 Crystal Output Frequency Signal (CGMXCLK)

CGMXCLK is the crystal oscillator output signal. It runs at the full speed of the crystal ( $f_{XCLK}$ ) and comes directly from the crystal oscillator circuit. **Figure 8-3** shows only the logical relation of CGMXCLK to OSC1 and OSC2 and may not represent the actual circuitry. The duty cycle of CGMXCLK is unknown and may depend on the crystal and other external factors. Also, the frequency and amplitude of CGMXCLK can be unstable at start-up.

#### 8.5.7 CGM Base Clock Output (CGMOUT)

CGMOUT is the clock output of the CGM. This signal goes to the SIM, which generates the MCU clocks. CGMOUT is a 50% duty cycle clock running at twice the bus frequency. CGMOUT is software programmable to be either the oscillator output, CGMXCLK, divided by two or the VCO clock, CGMVCLK, divided by two.

MC68HC708MP16 — Rev. 3.1

#### 8.5.8 CGM CPU Interrupt (CGMINT)

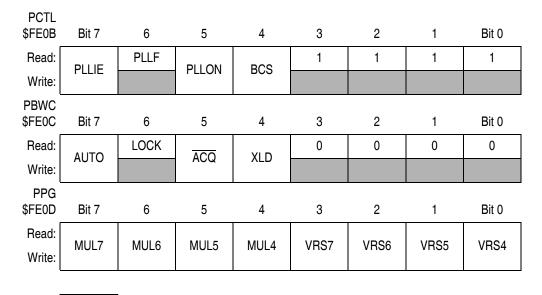

CGMINT is the interrupt signal generated by the PLL lock detector.

## 8.6 CGM Registers

The following registers control and monitor operation of the CGM:

- PLL control register (PCTL) (See 8.6.1 PLL Control Register.)
- PLL bandwidth control register (PBWC) (See 8.6.2 PLL Bandwidth Control Register.)
- PLL programming register (PPG) ((See 8.6.3 PLL Programming Register.)

Figure 8-4 is a summary of the CGM registers.

TEQ:

= Unimplemented

#### NOTES:

- 1. When AUTO = 0, PLLIE is forced to logic 0 and is read-only.
- 2. When AUTO = 0, PLLF and LOCK read as logic 0.
- 3. When AUTO = 1,  $\overline{ACQ}$  is read-only.
- 4. When PLLON = 0 or VRS[7:4] = \$0, BCS is forced to logic 0 and is read-only.
- 5. When PLLON = 1, the PLL programming register is read-only.
- 6. When BCS = 1, PLLON is forced set and is read-only.

Figure 8-4. CGM I/O Register Summary

#### 8.6.1 PLL Control Register

The PLL control register contains the interrupt enable and flag bits, the on/off switch, the base clock selector bit.

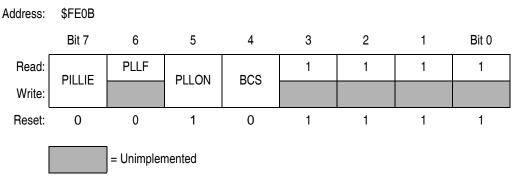

Figure 8-5. PLL Control Register (PCTL)

#### PLLIE — PLL Interrupt Enable Bit

This read/write bit enables the PLL to generate an interrupt request when the LOCK bit toggles, setting the PLL flag, PLLF. When the AUTO bit in the PLL bandwidth control register (PBWC) is clear, PLLIE cannot be written and reads as logic 0. Reset clears the PLLIE bit.

1 = PLL interrupts enabled

0 = PLL interrupts disabled

#### PLLF — PLL Interrupt Flag Bit

This read-only bit is set whenever the LOCK bit toggles. PLLF generates an interrupt request if the PLLIE bit also is set. PLLF always reads as logic 0 when the AUTO bit in the PLL bandwidth control register (PBWC) is clear. Clear the PLLF bit by reading the PLL control register. Reset clears the PLLF bit.

1 = Change in lock condition

0 = No change in lock condition

## **NOTE:** Do not inadvertently clear the PLLF bit. Any read or read-modify-write operation on the PLL control register clears the PLLF bit.

MC68HC708MP16 — Rev. 3.1

## **Clock Generator Module (CGM)**

#### PLLON — PLL On Bit

This read/write bit activates the PLL and enables the VCO clock, CGMVCLK. PLLON cannot be cleared if the VCO clock is driving the base clock, CGMOUT (BCS = 1). (See **8.4.3 Base Clock Selector Circuit**.) Reset sets this bit so that the loop can stabilize as the MCU is powering up.

1 = PLL on

0 = PLL off

#### BCS — Base Clock Select Bit

This read/write bit selects either the crystal oscillator output, CGMXCLK, or the VCO clock, CGMVCLK, as the source of the CGM output, CGMOUT. CGMOUT frequency is one-half the frequency of the selected clock. BCS cannot be set while the PLLON bit is clear. After toggling BCS, it may take up to three CGMXCLK and three CGMVCLK cycles to complete the transition from one source clock to the other. During the transition, CGMOUT is held in stasis. (See 8.4.3 Base Clock Selector Circuit.) Reset clears the BCS bit.

1 = CGMVCLK divided by two drives CGMOUT.

0 = CGMXCLK divided by two drives CGMOUT.

#### NOTE:

PLLON and BCS have built-in protection that prevents the base clock selector circuit from selecting the VCO clock as the source of the base clock if the PLL is off. Therefore, PLLON cannot be cleared when BCS is set, and BCS cannot be set when PLLON is clear. If the PLL is off (PLLON = 0), selecting CGMVCLK requires two writes to the PLL control register. (See **8.4.3 Base Clock Selector Circuit**.)

PCTL[3:0] — Unimplemented bits

These bits provide no function and always read as logic 1s.

#### 8.6.2 PLL Bandwidth Control Register

The PLL bandwidth control register does the following:

- Selects automatic or manual (software-controlled) bandwidth control mode
- Indicates when the PLL is locked
- In automatic bandwidth control mode, indicates when the PLL is in acquisition or tracking mode
- In manual operation, forces the PLL into acquisition or tracking mode.

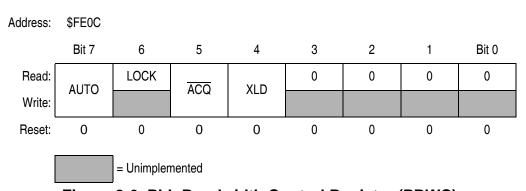

Figure 8-6. PLL Bandwidth Control Register (PBWC)

#### AUTO — Automatic Bandwidth Control Bit

This read/write bit selects automatic or manual bandwidth control. When initializing the PLL for manual operation (AUTO = 0), clear the  $\overline{ACQ}$  bit before turning on the PLL. Reset clears the AUTO bit.

- 1 = Automatic bandwidth control
- 0 = Manual bandwidth control

#### LOCK — Lock Indicator Bit

When the AUTO bit is set, LOCK is a read-only bit that becomes set when the VCO clock, CGMVCLK, is locked (running at the programmed frequency). When the AUTO bit is clear, LOCK reads as logic 0 and has no meaning. Reset clears the LOCK bit.

- 1 = VCO frequency correct or locked
- 0 = VCO frequency incorrect or unlocked

MC68HC708MP16 — Rev. 3.1

## **Clock Generator Module (CGM)**

### ACQ — Acquisition Mode Bit

When the AUTO bit is set, ACQ is a read-only bit that indicates whether the PLL is in acquisition mode or tracking mode. When the AUTO bit is clear,  $\overline{ACQ}$  is a read/write bit that controls whether the PLL is in acquisition or tracking mode.

In automatic bandwidth control mode (AUTO = 1), the last-written value from manual operation is stored in a temporary location and is recovered when manual operation resumes. Reset clears this bit, enabling acquisition mode.

- 1 = Tracking mode
- 0 = Acquisition mode

#### XLD — Crystal Loss Detect Bit

When the VCO output, CGMVCLK, is driving CGMOUT, this read/write bit can indicate whether the crystal reference frequency is active or not. To check the status of the crystal reference, do the following:

- 1. Write a logic 1 to XLD.
- 2. Wait  $N \times 4$  cycles. (N is the VCO frequency multiplier.)
- 3. Read XLD.
  - 1 = Crystal reference is not active
  - 0 = Crystal reference is active

The crystal loss detect function works only when the BCS bit is set, selecting CGMVCLK to drive CGMOUT. When BCS is clear, XLD always reads as logic 0.

#### PBWC[3:0] — Reserved for Test

These bits enable test functions not available in user mode. To ensure software portability from development systems to user applications, software should write zeros to PBWC[3:0] whenever writing to PBWC.

#### 8.6.3 PLL Programming Register

The PLL programming register contains the programming information for the modulo feedback divider and the programming information for the hardware configuration of the VCO.

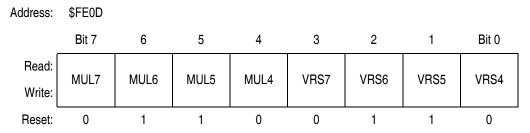

Figure 8-7. PLL Programming Register (PPG)

MUL[7:4] — Multiplier Select Bits

These read/write bits control the modulo feedback divider that selects the VCO frequency multiplier, N. (See **8.4.2.1 PLL Circuits** and **8.4.2.4 Programming the PLL**.) A value of \$0 in the multiplier select bits configures the modulo feedback divider the same as a value of \$1. Reset initializes these bits to \$6 to give a default multiply value of 6.

 1111
 15

Table 8-1. VCO Frequency Multiplier (N) Selection

**NOTE:** The multiplier select bits have built-in protection that prevents them from being written when the PLL is on (PLLON = 1).

VRS[7:4] — VCO Range Select Bits

These read/write bits control the hardware center-of-range linear multiplier L, which controls the hardware center-of-range frequency f<sub>VRS</sub>. (See 8.4.2.1 PLL Circuits, 8.4.2.4 Programming the PLL, and 8.6.1 PLL Control Register.) VRS[7:4] cannot be written when the PLLON bit in the PLL control register (PCTL) is set. (See 8.4.2.5 Special Programming Exceptions.) A value of \$0 in the VCO range select bits disables the PLL and clears the BCS bit in the PCTL. (See 8.4.3 Base Clock Selector Circuit and 8.4.2.5 Special Programming Exceptions for more information.) Reset initializes the bits to \$6 to give a default range multiply value of 6.

**NOTE:** The VCO range select bits have built-in protection that prevents them from being written when the PLL is on (PLLON = 1) and prevents selection of the VCO clock as the source of the base clock (BCS = 1) if the VCO range select bits are all clear.

The VCO range select bits must be programmed correctly. Incorrect programming may result in failure of the PLL to achieve lock.

## 8.7 Interrupts

When the AUTO bit is set in the PLL bandwidth control register (PBWC), the PLL can generate a CPU interrupt request every time the LOCK bit changes state. The PLLIE bit in the PLL control register (PCTL) enables CPU interrupts from the PLL. PLLF, the interrupt flag in the PCTL, becomes set whether interrupts are enabled or not. When the AUTO bit is clear, CPU interrupts from the PLL are disabled and PLLF reads as logic 0.

Software should read the LOCK bit after a PLL interrupt request to see if the request was due to an entry into lock or an exit from lock. When the PLL enters lock, the VCO clock, CGMVCLK, divided by two can be selected as the CGMOUT source by setting BCS in the PCTL. When the PLL exits lock, the VCO clock frequency is corrupt, and appropriate precautions should be taken. If the application is not frequency-sensitive, interrupts should be disabled to prevent PLL interrupt service routines from impeding software performance or from exceeding stack limitations.

#### **NOTE:**

Software can select the CGMVCLK divided by two as the CGMOUT source even if the PLL is not locked (LOCK = 0). Therefore, software should make sure the PLL is locked before setting the BCS bit.

#### 8.8 Wait Mode

The WAIT instruction puts the MCU in low-power-consumption standby mode.

The WAIT instruction does not affect the CGM. Before entering wait mode, software can disengage and turn off the PLL by clearing the BCS and PLLON bits in the PLL control register (PCTL). Less power-sensitive applications can disengage the PLL without turning it off. Applications that require the PLL to wake the MCU from wait mode also can deselect the PLL output without turning off the PLL.

## 8.9 CGM During Break Mode

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. (See 7.7.4 SIM Break Flag Control Register.)

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the PLLF bit during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write the PLL control register during the break state without affecting the PLLF bit.

## 8.10 Acquisition/Lock Time Specifications

The acquisition and lock times of the PLL are, in many applications, the most critical PLL design parameters. Proper design and use of the PLL ensures the highest stability and lowest acquisition/lock times.

#### 8.10.1 Acquisition/Lock Time Definitions

Typical control systems refer to the acquisition time or lock time as the reaction time, within specified tolerances, of the system to a step input. In a PLL, the step input occurs when the PLL is turned on or when it suffers a noise hit. The tolerance is usually specified as a percent of the step input or when the output settles to the desired value plus or minus a percent of the frequency change. Therefore, the reaction time is constant in this definition, regardless of the size of the step input. For example, consider a system with a 5% acquisition time tolerance. If a command instructs the system to change from 0 Hz to 1 MHz, the acquisition time is the time taken for the frequency to reach 1 MHz  $\pm$ 50 kHz. Fifty kHz = 5% of the 1-MHz step input. If the system is operating at 1 MHz and suffers a  $\pm$ 100-kHz noise hit, the acquisition time

is the time taken to return from 900 kHz to 1 MHz  $\pm 5$  kHz. Five kHz = 5% of the 100-kHz step input.

Other systems refer to acquisition and lock times as the time the system takes to reduce the error between the actual output and the desired output to within specified tolerances. Therefore, the acquisition or lock time varies according to the original error in the output. Minor errors may not even be registered. Typical PLL applications prefer to use this definition because the system requires the output frequency to be within a certain tolerance of the desired frequency regardless of the size of the initial error.

The discrepancy in these definitions makes it difficult to specify an acquisition or lock time for a typical PLL. Therefore, the definitions for acquisition and lock times for this module are as follows:

- Acquisition time, t<sub>ACQ</sub>, is the time the PLL takes to reduce the error between the actual output frequency and the desired output frequency to less than the tracking mode entry tolerance, Δ<sub>TRK</sub>. Acquisition time is based on an initial frequency error, (f<sub>DES</sub> f<sub>ORIG</sub>)/f<sub>DES</sub>, of not more than ±100%. In automatic bandwidth control mode (see 8.4.2.3 Manual and Automatic PLL Bandwidth Modes), acquisition time expires when the ACQ bit becomes set in the PLL bandwidth control register (PBWC).
- Lock time, t<sub>LOCK</sub>, is the time the PLL takes to reduce the error between the actual output frequency and the desired output frequency to less than the lock mode entry tolerance, Δ<sub>LOCK</sub>. Lock time is based on an initial frequency error, (f<sub>DES</sub> f<sub>ORIG</sub>)/f<sub>DES</sub>, of not more than ±100%. In automatic bandwidth control mode, lock time expires when the LOCK bit becomes set in the PLL bandwidth control register (PBWC). (See 8.4.2.3 Manual and Automatic PLL Bandwidth Modes.)

Obviously, the acquisition and lock times can vary according to how large the frequency error is and may be shorter or longer in many cases.

## **Clock Generator Module (CGM)**

#### 8.10.2 Parametric Influences on Reaction Time

Acquisition and lock times are designed to be as short as possible while still providing the highest possible stability. These reaction times are not constant, however. Many factors directly and indirectly affect the acquisition time.

The most critical parameter which affects the reaction times of the PLL is the reference frequency,  $f_{RDV}$ . This frequency is the input to the phase detector and controls how often the PLL makes corrections. For stability, the corrections must be small compared to the desired frequency, so several corrections are required to reduce the frequency error. Therefore, the slower the reference the longer it takes to make these corrections. This parameter is also under user control via the choice of crystal frequency,  $f_{XCLK}$ .

Another critical parameter is the external filter capacitor. The PLL modifies the voltage on the VCO by adding or subtracting charge from this capacitor. Therefore, the rate at which the voltage changes for a given frequency error (thus change in charge) is proportional to the capacitor size. The size of the capacitor also is related to the stability of the PLL. If the capacitor is too small, the PLL cannot make small enough adjustments to the voltage and the system cannot lock. If the capacitor is too large, the PLL may not be able to adjust the voltage in a reasonable time. (See **8.10.3 Choosing a Filter Capacitor**.)

Also important is the operating voltage potential applied to  $V_{DDA}$ . The power supply potential alters the characteristics of the PLL. A fixed value is best. Variable supplies, such as batteries, are acceptable if they vary within a known range at very slow speeds. Noise on the power supply is not acceptable, because it causes small frequency errors which continually change the acquisition time of the PLL.

Temperature and processing also can affect acquisition time because the electrical characteristics of the PLL change. The part operates as specified as long as these influences stay within the specified limits. External factors, however, can cause drastic changes in the operation of the PLL. These factors include noise injected into the PLL through the filter capacitor, filter capacitor leakage, stray impedances on the circuit board, and even humidity or circuit board contamination.

#### 8.10.3 Choosing a Filter Capacitor

As described in **8.10.2 Parametric Influences on Reaction Time**, the external filter capacitor,  $C_F$ , is critical to the stability and reaction time of the PLL. The PLL is also dependent on reference frequency and supply voltage. The value of the capacitor must, therefore, be chosen with supply potential and reference frequency in mind. For proper operation, the external filter capacitor must be chosen according to the following equation:

$$C_F = C_{FACT} \left( \frac{V_{DDA}}{f_{RDV}} \right)$$

For acceptable values of  $C_{FACT}$ , see **Table 21-10. CGM Acquisition/Lock Time Specifications**. For the value of  $V_{DDA}$ , choose the voltage potential at which the MCU is operating. If the power supply is variable, choose a value near the middle of the range of possible supply values.

This equation does not always yield a commonly available capacitor size, so round to the nearest available size. If the value is between two different sizes, choose the higher value for better stability. Choosing the lower size may seem attractive for acquisition time improvement, but the PLL can become unstable. Also, always choose a capacitor with a tight tolerance (±20% or better) and low dissipation.

#### 8.10.4 Reaction Time Calculation

The actual acquisition and lock times can be calculated using the equations below. These equations yield nominal values under the following conditions:

- Correct selection of filter capacitor, C<sub>F</sub> (See 8.10.3 Choosing a Filter Capacitor.)
- Room temperature operation
- Negligible external leakage on CGMXFC
- Negligible noise

MC68HC708MP16 — Rev. 3.1

## **Clock Generator Module (CGM)**

The K factor in the equations is derived from internal PLL parameters.  $K_{ACQ}$  is the K factor when the PLL is configured in acquisition mode, and  $K_{TRK}$  is the K factor when the PLL is configured in tracking mode. (See **8.4.2.2 Acquisition and Tracking Modes**.)

$$t_{\text{ACQ}} = \left(\frac{V_{\text{DDA}}}{f_{\text{RDV}}}\right) \left(\frac{8}{K_{\text{ACQ}}}\right)$$

$$t_{AL} = \left(\frac{V_{DDA}}{f_{RDV}}\right) \left(\frac{4}{K_{TRK}}\right)$$

$$t_{LOCK} = t_{ACQ} + t_{AL}$$

Note the inverse proportionality between the lock time and the reference frequency.

In automatic bandwidth control mode, the acquisition and lock times are quantized into units based on the reference frequency. (See 8.4.2.3 Manual and Automatic PLL Bandwidth Modes.) A certain number of clock cycles,  $n_{ACQ}$ , is required to ascertain that the PLL is within the tracking mode entry tolerance,  $\Delta_{TRK}$ , before exiting acquisition mode. A certain number of clock cycles,  $n_{TRK}$ , is required to ascertain that the PLL is within the lock mode entry tolerance,  $\Delta_{LOCK}$ . Therefore, the acquisition time,  $t_{ACQ}$ , is an integer multiple of  $n_{ACQ}/f_{RDV}$ , and the acquisition to lock time,  $t_{AL}$ , is an integer multiple of  $n_{TRK}/f_{RDV}$ . Also, since the average frequency over the entire measurement period must be within the specified tolerance, the total time usually is longer than  $t_{LOCK}$  as calculated above.

In manual mode, it is usually necessary to wait considerably longer than  $t_{LOCK}$  before selecting the PLL clock (see **8.4.3 Base Clock Selector Circuit**) because the factors described in **8.10.2 Parametric Influences on Reaction Time** may slow the lock time considerably.

#### 9.2 Introduction

This section describes the pulse width modulator for motor control (PWMMC, Version A). The MC68HC(7)08MP16 PWM module can generate three complementary PWM pairs or six independent PWM signals. These PWM signals can be center-aligned or edge-aligned. A block diagram of the PWM module is shown in **Figure 9-1**.

A12-bit timer PWM counter is common to all six channels. PWM resolution is one clock period for edge-aligned operation and two clock periods for center-aligned operation. The clock period is dependent on the internal operating frequency ( $f_{op}$ ) and a programmable prescaler. The highest resolution for edge-aligned operation is 125 ns ( $f_{op}$  = 8 MHz). The highest resolution for center-aligned operation is 250 ns ( $f_{op}$  = 8 MHz).

When generating complementary PWM signals, the module features automatic dead-time insertion to the PWM output pairs and transparent toggling of PWM data based upon sensed motor phase current polarity.

A summary of the PWM registers is shown in Figure 9-2.

#### 9.3 Features

Features of the PWMMC include the following:

- Three complimentary PWM pairs or six independent PWM signals
- Edge-aligned PWM signals or center-aligned PWM signals
- PWM signal polarity control
- 20 mA current sink capability on PWM pins
- Manual PWM output control through software
- Programmable fault protection
- Complimentary mode also features:
  - Dead-time insertion
  - Separate top/bottom pulse width correction via current sensing or programmable software bits

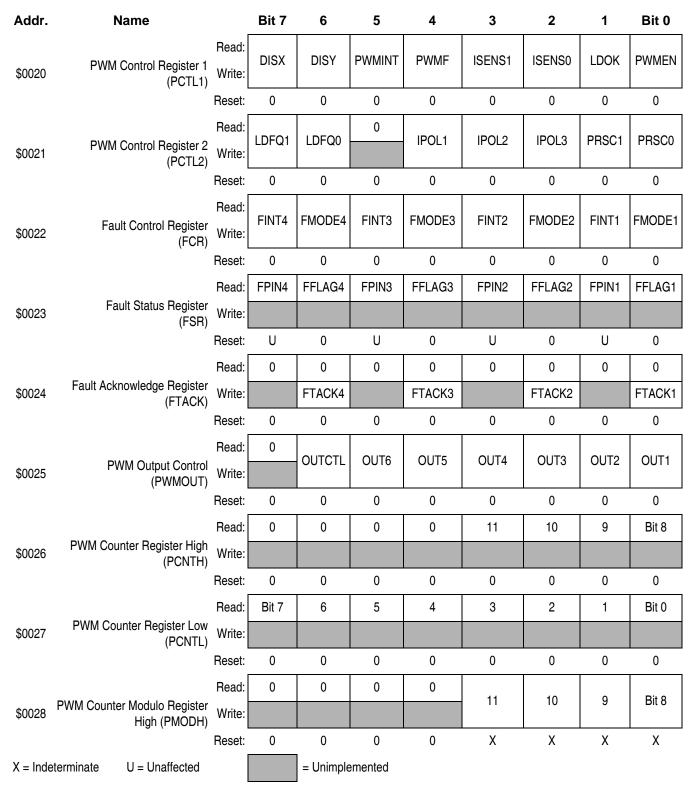

Figure 9-2. PWMMC Register Summary

#### 9.4 Timebase

Refer to the following subsections for a discussion of the timebase.

#### 9.4.1 Resolution

In center-aligned mode, a 12-bit up/down counter is used to create the PWM period. Therefore, the PWM resolution in center-aligned mode is two clocks (highest resolution is 250 ns @  $f_{op} = 8$  MHz) as shown in **Figure 9-3**. The up/down counter uses the value in the timer modulus register to determine its maximum count. The PWM period will equal: [(timer modulus) x (PWM clock period) x 2].

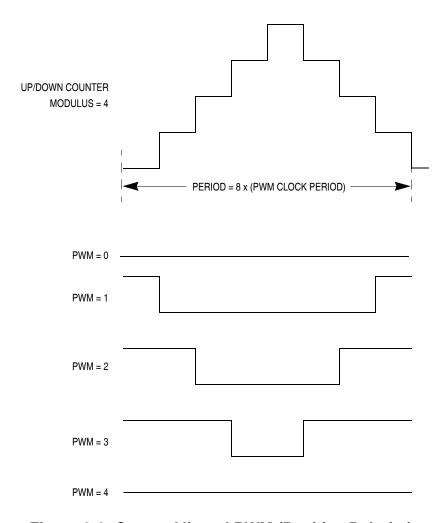

Figure 9-3. Center-Aligned PWM (Positive Polarity)

MC68HC708MP16 - Rev. 3.1

## **Pulse Width Modulator for Motor Control (PWMMC)**

For edge-aligned mode, a 12-bit up-only counter is used to create the PWM period. Therefore, the PWM resolution in edge-aligned mode is one clock (highest resolution is125 ns @  $f_{op} = 8$  MHz) as shown in **Figure 9-4**. Again, the timer modulus register is used to determine the maximum count. The PWM period will equal: [(timer modulus) x (PWM clock period)].

Center-aligned operation versus edge-aligned operation is determined by the option EDGE. See **5.3 Functional Description**.

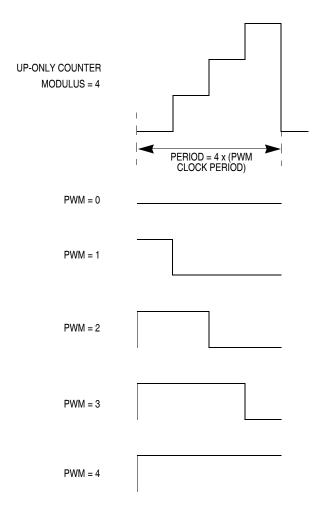

Figure 9-4. Edge-Aligned PWM (Positive Polarity)

#### 9.4.2 Prescaler

To permit lower PWM frequencies, a prescaler is provided which will divide the PWM clock frequency by 1, 2, 4, or 8. **Table 9-1** shows how setting the prescaler bits in PWM control register 2 affects the PWM clock frequency. This prescaler is buffered and will not be used by the PWM generator until the LDOK bit is set and a new PWM reload-cycle begins.

 Prescaler Bits PRSC1:PRSC0
 PWM Clock Frequency

 00
 f<sub>op</sub>

 01
 f<sub>op</sub>/2

 10
 f<sub>op</sub>/4

 11
 f<sub>op</sub>/8

**Table 9-1. PWM Prescaler** 

#### 9.5 PWM Generators

Pulse width modulator (PWM) generators are discussed in the following subsections.

#### 9.5.1 Load Operation

To help avoid erroneous pulse widths and PWM periods, the modulus, prescaler, and PWM value registers are buffered. New PWM values, counter modulus values, and prescalers can be loaded from their buffers into the PWM module every one, two, four, or eight PWM cycles. LDFQ1:LDFQ0 in PWM control register 2 are used to control this reload frequency, as shown in Table 9-2. When a reload cycle arrives, regardless of whether an actual reload occurs (as determined by the LDOK bit), the PWM reload flag bit in PWM control register 1 will be set. If the PWMINT bit in PWM control register 1 is set, a CPU interrupt request will be generated when PWMF is set. Software can use this interrupt to calculate new PWM parameters in real time for the PWM module.

MC68HC708MP16 - Rev. 3.1

Table 9-2. PWM Reload Frequency

Reload Frequency Bits LDFQ1:LDFQ0	PWM Reload Frequency
00	Every PWM cycle
01	Every 2 PWM cycles
10	Every 4 PWM cycles
11	Every 8 PWM cycles

For ease of software, the LDFQx bits are buffered. When the LDFQx bits are changed, the reload frequency will not change until the previous reload cycle is completed. See **Figure 9-5**.

**NOTE:** When reading the LDFQx bits, the value is the buffered value (for example, not necessarily the value being acted upon).

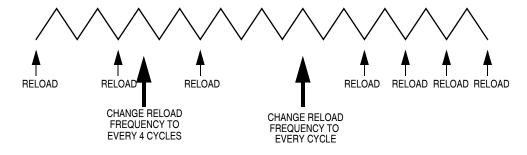

Figure 9-5. Reload Frequency Change

PWMINT enables CPU interrupt requests as shown in **Figure 9-6**. When this bit is set, CPU interrupt requests are generated when the PWMF bit is set. When the PWMINT bit is clear, PWM interrupt requests are inhibited. PWM reloads will still occur at the reload rate, but no interrupt requests will be generated.

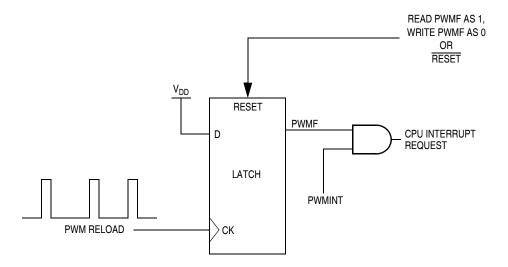

Figure 9-6. PWM Interrupt Requests

To prevent a partial reload of PWM parameters from occurring while the software is still calculating them, an interlock bit controlled from software is provided. This bit informs the PWM module that all the PWM parameters have been calculated, and it is "okay" to use them. A new modulus, prescaler, and/or PWM value cannot be loaded into the PWM module until the LDOK bit in PWM control register 1 is set. When the LDOK bit is set, these new values are loaded into a second set of registers and used by the PWM generator at the beginning of the next PWM reload cycle as shown in **Figure 9-7**, **Figure 9-8**, **Figure 9-9**, and **Figure 9-10**. After these values are loaded, the LDOK bit is cleared.

NOTE:

When the PWM module is enabled (via the PWMEN bit), a load will occur if the LDOK bit is set. Even if it is not set, an interrupt will occur if the PWMINT bit is set. To prevent this, the software should clear the PWMINT bit before enabling the PWM module.

## **Pulse Width Modulator for Motor Control (PWMMC)**

#### 9.5.2 PWM Data Overflow and Underflow Conditions

The PWM value registers are 16-bit registers. Although the counter is only 12 bits, the user may write a 16-bit signed value to a PWM value register. As shown in **Figure 9-3** and **Figure 9-4**, if the PWM value is less than or equal to zero, the PWM will be inactive for the entire period. Conversely, if the PWM value is greater than or equal to the timer modulus, the PWM will be active for the entire period. Refer to **Table 9-3**.

#### **NOTE:**

The terms "active" and "inactive" refer to the asserted and negated states of the PWM signals and should not be confused with the high impedance state of the PWM pins.

**Table 9-3. PWM Data Overflow and Underflow Conditions** 

PWMVALxH:PWMVALxL	Condition	PWM Value Used
\$0000 - \$0FFF	Normal	(Per Registers Contents)
\$1000 – \$7FFF	Overflow	\$FFF
\$8000 – \$FFFF	Underflow	\$000

## 9.6 Output Control

The following subsections discuss output control.

## 9.6.1 Selecting Six Independent PWMs or Three Complementary PWM Pairs

The PWM outputs can be configured as six independent PWM channels or three complementary channel pairs. The option INDEP determines which mode is used (see **5.3 Functional Description**). If complementary operation is chosen, the PWM pins are paired as shown in **Figure 9-11**. Operation of one pair is then determined by one PWM value register. This type of operation is meant for use in motor drive circuits such as the one in **Figure 9-12**.

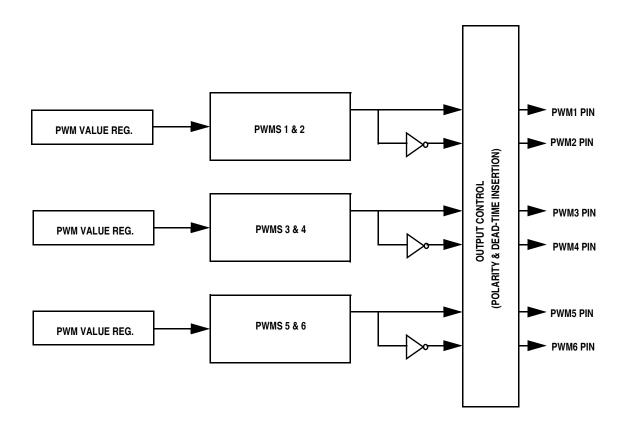

Figure 9-11. Complementary Pairing

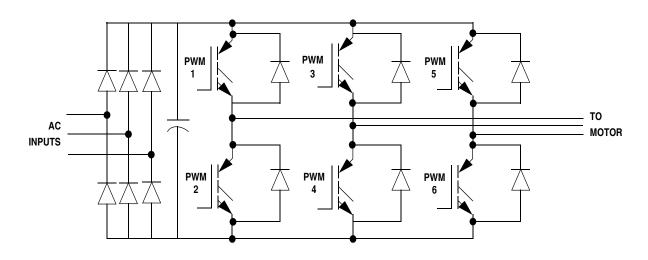

Figure 9-12. Typical AC Motor Drive

MC68HC708MP16 - Rev. 3.1

## Pulse Width Modulator for Motor Control (PWMMC)

When complementary operation is used, two additional features are provided:

- Dead-time insertion
- Separate top/bottom pulse width correction to correct for distortions caused by the motor drive characteristics.

If independent operation is chosen, each PWM has its own PWM value register.

#### 9.6.2 Dead-Time Insertion

As shown in **Figure 9-12**, in complementary mode, each PWM pair can be used to drive top-side/bottom-side transistors.

When controlling DC-to-AC inverters such as this, the top and bottom PWMs in one pair should *never* be active at the same time. In **Figure 9-12**, if PWM1 and PWM2 were on at the same time, large currents would flow through the two transistors as they discharge the bus capacitor. The IGBTs could be weakened or destroyed.

Simply forcing the two PWMs to be inversions of each other is not always sufficient. Since a time delay is associated with turning off the transistors in the motor drive, there must be a "dead-time" between the deactivation of one PWM and the activation of the other.

A dead-time can be specified in the dead-time write-once register. This 8-bit value specifies the number of CPU clock cycles to use for the dead-time. The dead-time is not affected by changes in the PWM period caused by the prescaler.

Dead-time insertion is achieved by feeding the top PWM outputs of the PWM generator into dead-time generators, as shown in **Figure 9-13**. Current sensing determines which PWM value of a PWM generator pair to use for the TOP PWM in the next PWM cycle. (See **9.6.3 Top/Bottom Correction**.) When output control is enabled, the odd OUT bits, rather than the PWM generator outputs, are fed into the dead-time generators. (See **9.6.5 Output Port Control**.)

MC68HC708MP16 — Rev. 3.1

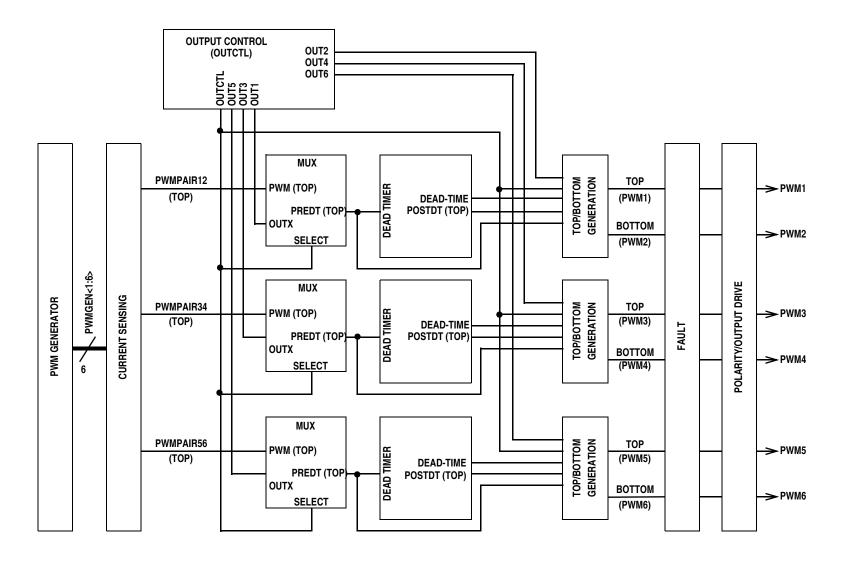

Figure 9-13. Dead-Time Generators

Whenever an input to a dead-time generator transitions, a dead-time is inserted (for example, both PWMs in the pair are forced to their inactive state). The BOTTOM PWM signal is generated from the TOP PWM and the dead-time. In the case of output control enabled, the odd OUTx bits control the top PWMs, the even OUTx bits control the bottom PWMs with respect to the odd OUTx bits. (See Table 9-7.) Figure 9-14 shows the effects of the dead-time insertion.

As seen in **Figure 9-14**, some pulse width distortion occurs when the dead-time is inserted. The active pulse widths are reduced. For example, in **Figure 9-14**, when the PWM value register is equal to two, the ideal waveform (with no dead-time) has pulse widths equal to four. However, the actual pulse widths shrink to two after a dead-time of two was inserted. In this example, with the prescaler set to divide by one and center-aligned operation selected, this distortion can be compensated for by adding or subtracting half the dead-time value to or from the PWM register value. This correction is further described in **9.6.3 Top/Bottom Correction**.

Further examples of dead-time insertion are shown in **Figure 9-15** and **Figure 9-16**. **Figure 9-15** shows the effects of dead-time insertion at the duty cycle boundaries (near 0% and 100% duty cycles). **Figure 9-16** shows the effects of dead-time insertion on pulse widths smaller than the dead-time.

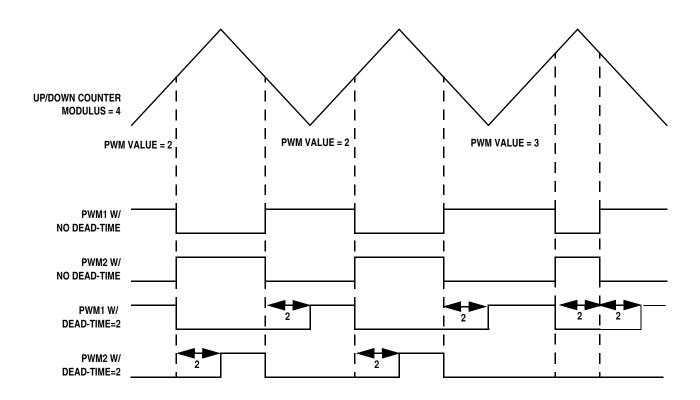

Figure 9-14. Effects of Dead-Time Insertion

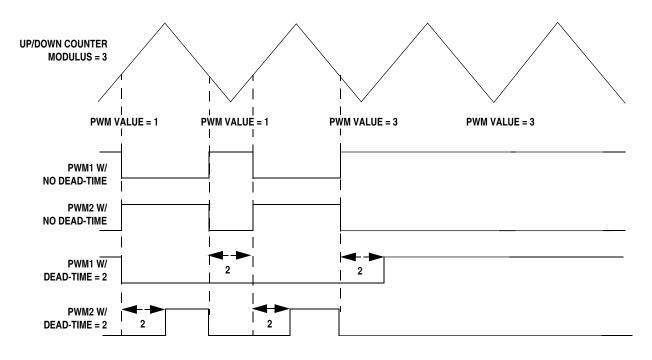

Figure 9-15. Dead-Time at Duty Cycle Boundaries

MC68HC708MP16 - Rev. 3.1

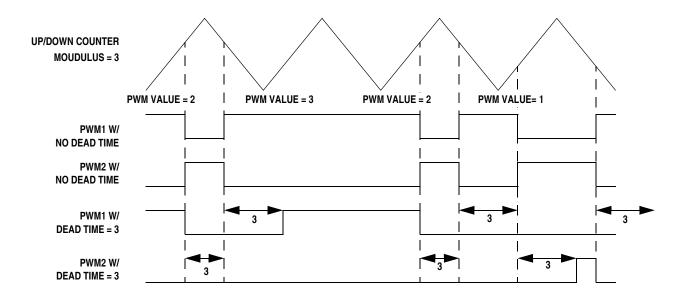

Figure 9-16. Dead-Time and Small Pulse Widths

#### 9.6.3 Top/Bottom Correction

In a half-bridge AC motor drive, either the top or the bottom transistor controls the output voltage at any given time. The direction of the motor current determines which transistor controls the output.

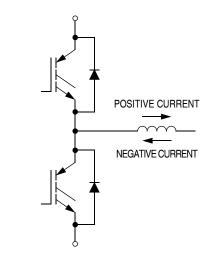

Figure 9-17. Current Convention

During deadtime, both transistors in a half-bridge are off, allowing the load voltage to float and introducing distortion in the output voltage.

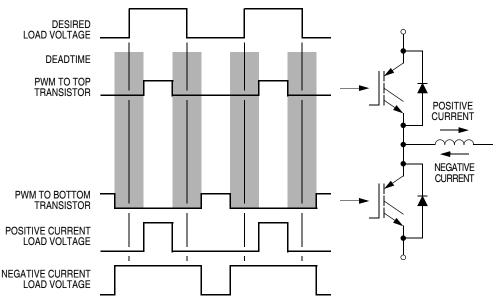

Figure 9-18. Deadtime Distortion

MC68HC708MP16 - Rev. 3.1

During deadtime, load inductance distorts output voltage by keeping inductive current flowing through the diodes. Inductive distortion either lengthens or shortens the pulse width by one deadtime interval, depending on current direction. This deadtime distortion then either increases or decreases the averaged sinusoidal output voltage.

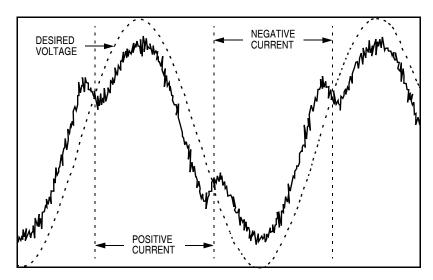

Figure 9-19. Sinusoidal Distortion of Load Voltage

In complementary channel operation, either the odd-numbered or the even-numbered PWMVAL registers control the pulse width at any given time. For a given PWM pair, whether the odd or even PWMVAL registers are active depends on either:

- The state of the current-sensing pin, ISx, for that driver, or
- The state of the output polarity bit, IPOLx, for that driver

To correct deadtime distortion, software can decrease or increase the value in the appropriate PWMVAL register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime compensates for deadtime distortion.
- In center aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime compensates for deadtime distortion.

In complementary channel operation, the ISENS1–3 bits in PWM control register 1 select one of three correction methods:

- Manual correction
- Automatic current-sensing correction during deadtime
- Automatic current sensing correction when the PWM counter value equals the value in the PWM counter modulus registers.

**Table 9-4. Correction Method Selection** 

ISENS[1:0]	Correction method
0X	Manual correction with IPOL1–IPOL3 bits; or for no correction
10	Automatic current-sensing correction on pins $\overline{IS1}$ , $\overline{IS2}$ , and $\overline{IS3}$ during deadtime <sup>(1)</sup>
11	Automatic current-sensing correction on pins $\overline{IS1}$ , $\overline{IS2}$ , and $\overline{IS3}^{(2)}$ At the half cycle in center-aligned operation At the end of the cycle in edge-aligned operation

The polarity of the ISx pin is latched when both the top and bottom PWMs are off. At the 0% and 100% duty cycle boundaries, there is no deadtime, so no new current value is sensed.

**NOTE:** The ISENSx bits are not buffered; therefore, changing the current sensing method can affect the present PWM cycle.

<sup>2.</sup> Current is sensed even with 0% or 100% duty cycle.

#### 9.6.3.1 Manual Correction

The IPOL1–IPOL3 bits select either the odd or the even PWM value registers to use in the next PWM cycle.

•		
Bit	Logic state	Output control
IPOL1	0	PMVAL1 controls PWM1/PWM2 pair
	1	PMVAL2 controls PWM1/PWM2 pair
IPOL2	0	PMVAL3 controls PWM3/PWM4 pair
	1	PMVAL4 controls PWM3/PWM4 pair
IPOL3	0	PMVAL5 controls PWM5/PWM6 pair
	1	PMVAL6 controls PWM5/PWM6 pair

Table 9-5. Top/Bottom Manual Correction

NOTE:

The IPOLx bits are buffered so that only one PWM register is used per PWM cycle. If an IPOLx bit changes during a PWM period, the new value does not take effect until the next PWM period.

The IPOLx bits take effect at the end of each PWM cycle regardless of the state of the load okay bit, LDOK.

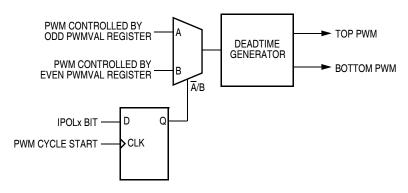

Figure 9-20. Internal Correction Logic when ISENS[1:0] = 0X

The best time to change from one PWMVAL register to another is just before the current zero crossing. **Figure 9-21** shows motor voltage waveforms under high current and low current conditions. During a

В В **DEADTIME** PWM TO TOP **TRANSISTOR POSITIVE** CURRENT **NEGATIVE CURRENT** PWM TO BOTTOM **TRANSISTOR** LOAD VOLTAGE WITH HIGH POSITIVE CURRENT LOAD VOLTAGE WITH LOW POSITIVE CURRENT LOAD VOLTAGE WITH HIGH NEGATIVE CURRENT LOAD VOLTAGE WITH LOW NEGATIVE CURRENT

deadtime interval, the load voltage near a current zero crossing is somewhere between the high and low levels.

Figure 9-21. Output Voltage Waveforms

T = DEADTIME INTERVAL BEFORE ASSERTION OF TOP PWM B = DEADTIME INTERVAL BEFORE ASSERTION OF BOTTOM PWM

Each ISx pin is sampled twice in a PWM period. The values are stored in the DTx bits in the fault acknowlege register. The DTx bits are a timing marker to indicate when to toggle between PWMVAL register. In the low-current condition immediately before a current zero crossing, the two DTx bits in a pair have dissimilar values. Software can then set the IPOLx bit to toggle PWMVAL registers before the zero crossing ocurs.

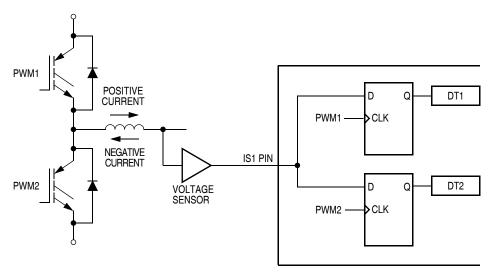

Figure 9-22. DTx bits

#### 9.6.3.2 Automatic Correction

The current sense pin,  $\overline{\text{ISx}}$ , for a PWM pair selects either the odd or the even PWM value registers to use in the next PWM cycle. The selection is based on user-provided current sense circuitry driving the  $\overline{\text{ISx}}$  pin high for negative current and low for positive current.

**Table 9-6. Top/Bottom Current-Sense Correction** 

Pin	Logic State	Output Control
īS1	0	PMVAL1 controls PWM1/PWM2 pair
	1	PMVAL2 controls PWM1/PWM2 pair
ĪS2	0	PMVAL3 controls PWM3/PWM4 pair
	1	PMVAL4 controls PWM3/PWM4 pair
īS3	0	PMVAL5 controls PWM5/PWM6 pair
	1	PMVAL6 controls PWM5/PWM6 pair

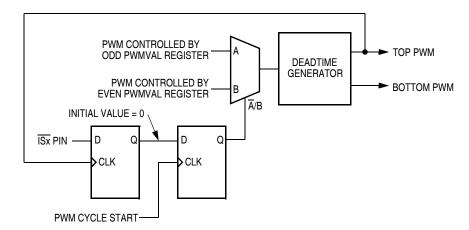

Figure 9-23. Internal Correction Logic when ISENS[1:0] = 10

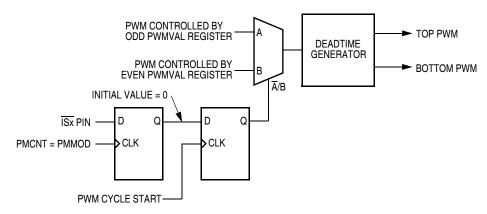

Figure 9-24. Internal Correction Logic when ISENS[1:0] = 11

**NOTE:** The values latched on the ISx pins are buffered so that only one PWM register is used per PWM cycle. If a current sense value changes during a PWM period, the new value does not take effect until the next PWM period.

When initially enabled by setting the PWMEN bit, no current has previously been sensed. PWM value registers 1, 3, and 5 initially control the three PWM pairs when configured for current sensing correction.

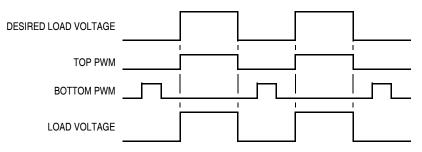

Figure 9-25. Correction with Positive Current

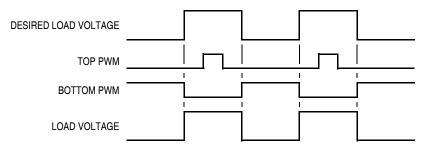

Figure 9-26. Correction with Negative Current

### 9.6.4 Output Polarity

The output polarity of the PWMs is determined by two options: TOPNEG and BOTNEG. The top polarity option, TOPNEG, controls the polarity of PWMs 1, 3, and 5. The bottom polarity option, BOTNEG, controls the polarity of PWMs 2, 4, and 6. Positive polarity means that when the PWM is active, the PWM output is high. Conversely, negative polarity means that when the PWM is active, PWM output is low. See **Figure 9-27** and **Section 5. Configuration Register (CONFIG)**.

**NOTE:** 

Both bits are found in the CONFIG register, which is a write-once register. This reduces the chances of the software inadvertently changing the polarity of the PWM signals and possibly damaging the motor drive hardware.

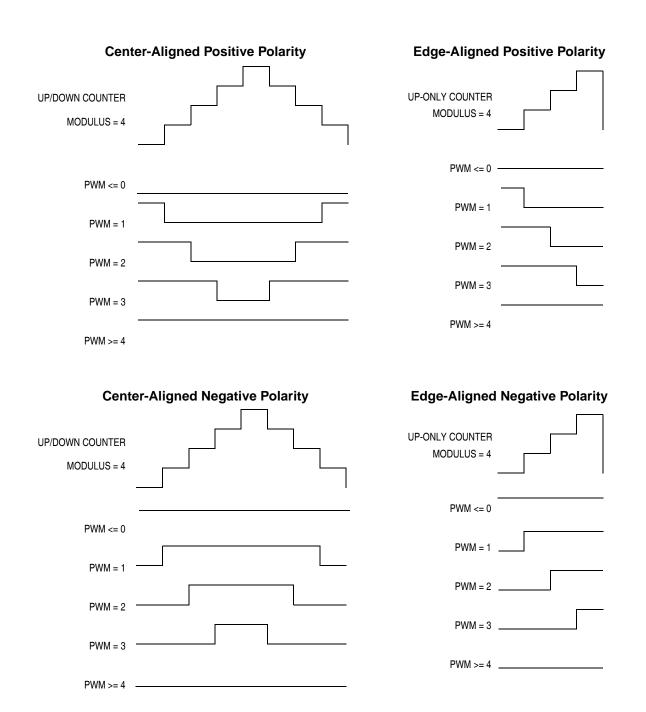

Figure 9-27. PWM Polarity

#### 9.6.5 Output Port Control

Conditions may arise in which the PWM pins need to be individually controlled. This is made possible by the PWM output control register (PWMOUT) shown in **Figure 9-28**.

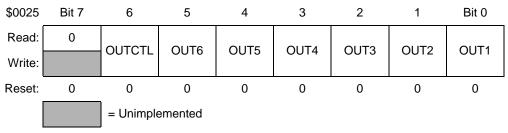

Figure 9-28. PWM Output Control Register (PWMOUT)

If the OUTCTL bit is set, the PWM pins can be controlled by the OUTx bits. These bits behave according to **Table 9-7**.

OUTx Bit	Complementary Mode	Independent Mode
OUT1	1 — PWM1 is active 0 — PWM1 is inactive	1 — PWM1 is active 0 — PWM1 is inactive
OUT2	1 — PWM2 is complement of PWM 1 0 — PWM2 is inactive	1 — PWM2 is active 0 — PWM2 is inactive
OUT3	1 — PWM3 is active 0 — PWM3 is inactive	1 — PWM3 is active 0 — PWM3 is inactive
OUT4	1 — PWM4 is complement of PWM 3 0 — PWM4 is inactive	1 — PWM4 is active 0 — PWM4 is inactive
OUT5	1 — PWM5 is active 0 — PWM5 is inactive	1 — PWM5 is active 0 — PWM5 is inactive
OUT6	1 — PWM 6 is complement of PWM 5 0 — PWM6 is inactive	1 — PWM6 is active 0 — PWM6 is inactive

Table 9-7. OUTx Bits

When OUTCTL is set, the polarity options TOPPOL and BOTPOL will still affect the outputs. In addition, if complementary operation is in use, the PWM pairs will not be allowed to be active simultaneously, and dead-time will still not be violated. When OUTCTL is set and complimentary operation is in use, the odd OUTx bits are inputs to the dead-time generators as shown in **Figure 9-13**. Dead-time is inserted whenever

the odd OUTx bit toggles as shown in **Figure 9-29**. Although dead-time is not inserted when the even OUTx bits change, there will be no dead-time violation as shown in **Figure 9-30**.

Setting the OUTCTL bit does not disable the PWM generator and current sensing circuitry. They continue to run, but are no longer controlling the output pins. In addition, OUTCTL will control the PWM pins even when PWMEN = 0. When OUTCTL is cleared, the outputs of the PWM generator become the inputs to the dead-time and output circuitry at the beginning of the next PWM cycle.

NOTE:

To avoid an unexpected dead-time occurrence, it is recommended that the OUTx bits be cleared prior to entering and prior to exiting individual PWM output control mode.

#### 9.7 Fault Protection

Conditions may arise in the external drive circuitry which require that the PWM signals become inactive immediately, such as an overcurrent fault condition. Furthermore, it may be desirable to selectively disable PWM(s) solely with software.

One or more PWM pins can be disabled (forced to their inactive state) by applying a logic high to any of the four external fault pins or by writing a logic high to either of the disable bits (DISX and DISY in PWM control register 1). Figure 9-31 shows the structure of the PWM disabling scheme. While the PWM pins are disabled, they are forced to their inactive state. The PWM generator continues to run — only the output pins are disabled.

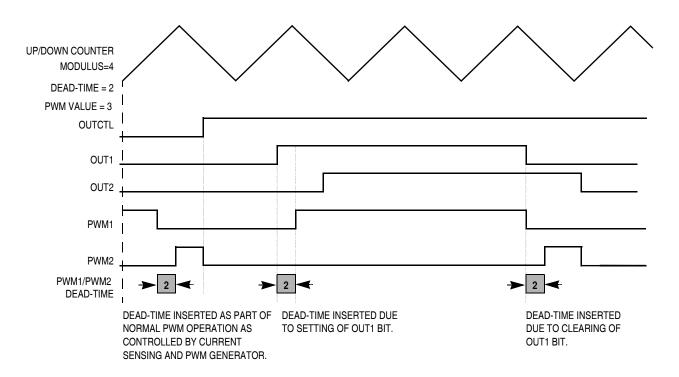

Figure 9-29. Dead-Time Insertion During OUTCTL = 1

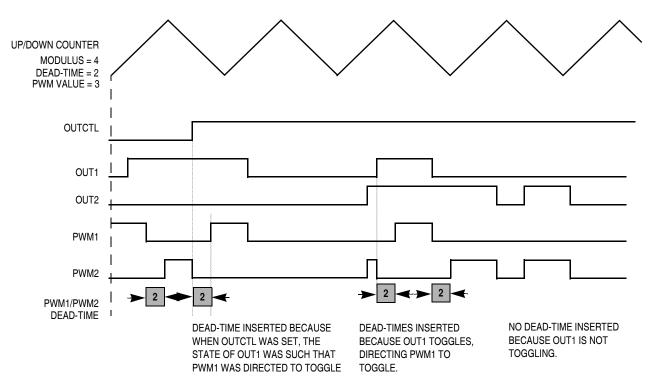

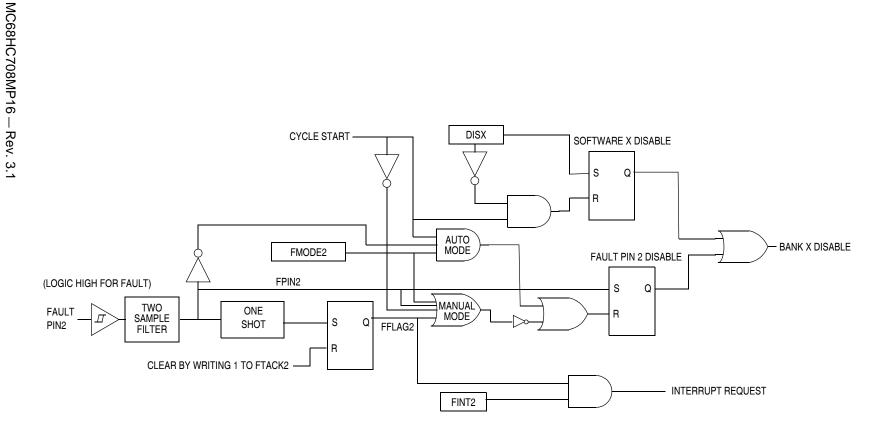

Figure 9-30. Dead-Time Insertion During OUTCTL = 1

Technical Data MC68HC708MP16 — Rev. 3.1

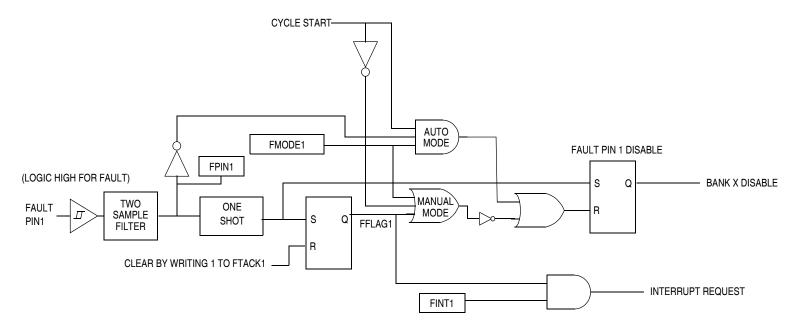

The example is of fault pin 2 with DISX. Fault pin 4 with DISY is logically similar and affects BANK Y disable.

NOTE: In manual mode (FMODE = 0) fault 2 and 4 may be cleared only if a logic level low at the input of the fault pin is present.

Figure 9-31. PWM Disabling Scheme (Sheet 1 of 2)

MC68HC708MP16 — Rev. 3.1

The example is of fault pin 1. Fault pin 3 is logically similar and effects BANK Y disable.

NOTE: In manual mode (FMODE = 0) fault 1 and 3 may be cleared regardless of the logic level at the input of the fault pin.

Figure 9-32. PWM Disabling Scheme (Sheet 2 of 2)

To allow for different motor configurations and the controlling of more than one motor, the PWM disabling function is organized as two banks, bank X and bank Y. Bank information combines with information from the disable mapping register to allow selective PWM disabling. Fault pin 1, fault pin 2, and PWM disable bit X constitute the disabling function of bank X. Fault pin 3, fault pin 4, and PWM disable bit Y constitute the disabling function of bank Y. **Figure 9-33** and **Figure 9-34** show the disable mapping write-once register and the decoding scheme of the bank which selectively disables PWM(s). When all bits of the disable mapping register are set, any disable condition will disable all PWMs.

A fault can also generate a CPU interrupt. Each fault pin has its own interrupt vector.

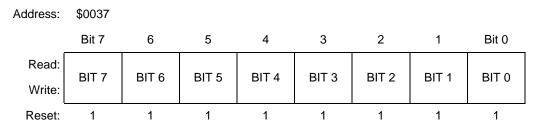

Figure 9-33. PWM Disable Mapping Write-Once Register (DISMAP)

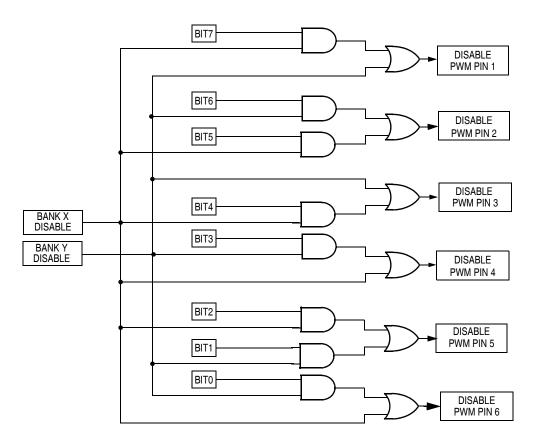

Figure 9-34. PWM Disabling Decode Scheme

#### 9.7.1 Fault Condition Input Pins

A logic high level on a fault pin disables the respective PWM(s) determined by the bank and the disable mapping register. Each fault pin incorporates a filter to assist in rejecting spurious faults. All of the external fault pins are software-configurable to re-enable the PWMs either with the fault pin (automatic mode) or with software (manual mode). Each fault pin has an associated FMODE bit to control the PWM re-enabling method. Automatic mode is selected by setting the FMODEx bit in the fault control register. Manual mode is selected when FMODEx is clear.

#### 9.7.1.1 Fault Pin Filter

Each fault pin incorporates a filter to assist in determining a genuine fault condition. After a fault pin has been logic low for one CPU cycle, a rising edge (logic high) will be synchronously sampled once per CPU cycle for two cycles. If both samples are detected logic high, the corresponding FPIN bit and FFLAG bit will be set. The FPIN bit will remain set until the corresponding fault pin is logic low and synchronously sampled once in the following CPU cycle.

#### 9.7.1.2 Automatic Mode

In automatic mode, the PWM(s) are disabled immediately once a filtered fault condition is detected (logic high). The PWM(s) remain disabled until the filtered fault condition is cleared (logic low) and a new PWM cycle begins as shown in **Figure 9-35**. Clearing the corresponding FFLAGx event bit will not enable the PWMs in automatic mode.

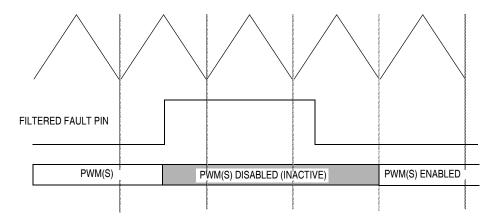

Figure 9-35. PWM Disabling in Automatic Mode

The filtered fault pins' logic state is reflected in the respective FPINx bit. Any write to this bit is overwritten by the pin state. The FFLAGx event bit is set with each rising edge of the respective fault pin after filtering has been applied. To clear the FFLAGx bit, the user must write a 1 to the corresponding FTACKx bit.

MC68HC708MP16 — Rev. 3.1

If the FINTx bit is set, a fault condition resulting in setting the corresponding FFLAG bit will also latch a CPU interrupt request. The interrupt request latch is not cleared until one of the following actions occurs:

- The FFLAGx bit is cleared by writing a 1 to the corresponding FTACKx bit.
- Clearing the FINTx bit. (This will not clear the FFLAGx bit.)
- Reset A reset automatically clears all four interrupt latches

If prior to a vector fetch, the interrupt request latch is cleared by one of the above actions, a CPU interrupt will no longer be requested. A vector fetch does not alter the state of the PWMs, the FFLAGx event flag or FINTx.

**NOTE:** If the FFLAGx or FINTx bits are not cleared during the interrupt service routine, the interrupt request latch will not be cleared.

#### 9.7.1.3 Manual Mode

In manual mode, the PWM(s) are disabled immediately once a filtered fault condition is detected (logic high). The PWM(s) remain disabled until software clears the corresponding FFLAGx event bit and a new PWM cycle begins. In manual mode, the fault pins are grouped in pairs, each pair sharing common functionality. A fault condition on pins 1 and 3 may be cleared, allowing the PWM(s) to enable at the start of a PWM cycle regardless of the logic level at the fault pin. See **Figure 9-36**. A fault condition on pins 2 and 4 can only be cleared, allowing the PWM(s) to enable, if a logic low level at the fault pin is present at the start of a PWM cycle. See **Figure 9-37**.

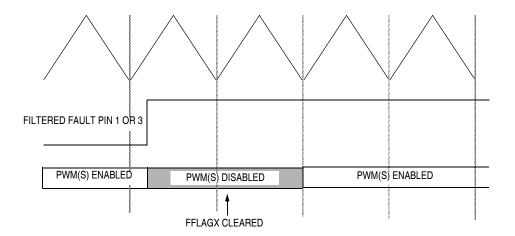

Figure 9-36. PWM Disabling in Manual Mode (Example 1)

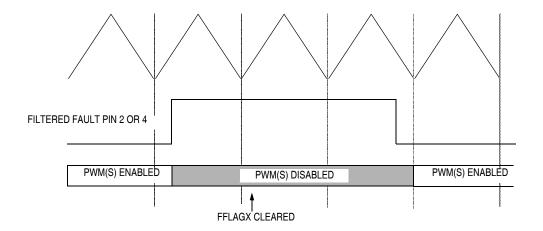

Figure 9-37. PWM Disabling in Manual Mode (Example 2)

The function of the fault control and event bits is the same as in automatic mode except that the PWMs are not re-enabled until the FFLAGx event bit is cleared by writing to the FTACKx bit and the filtered fault condition is cleared (logic low).

### 9.7.2 Software Output Disable

Setting PWM disable bit DISX or DISY in PWM control register 1 immediately disables the corresponding PWM pins as determined by the bank and disable mapping register. The PWM pin(s) remain disabled until the PWM disable bit is cleared and a new PWM cycle begins as shown in **Figure 9-38**. Setting a PWM disable bit does not latch a CPU interrupt request, and there are no event flags associated with the PWM disable bits.

#### 9.7.3 Output Port Control

When operating the PWMs using the OUTx bits (OUTCTL = 1), fault protection applies as described in this section. Due to the absence of periodic PWM cycles, fault conditions are cleared upon each CPU cycle and the PWM outputs are re-enabled, provided all fault clearing conditions are satisfied.

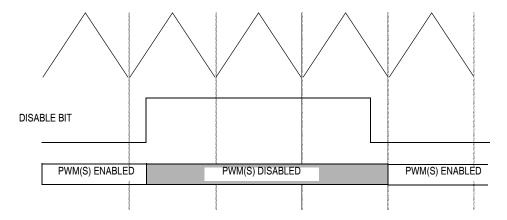

Figure 9-38. PWM Software Disable

#### 9.8 Initialization and the PWMEN Bit

For proper operation, all registers should be initialized and the LDOK bit should be set before enabling the PWM via the PWMEN bit. When the PWMEN bit is first set, a reload will occur immediately, setting the PWMF flag and generating an interrupt if PWMINT is set. In addition, in complementary mode, PWM value registers 1, 3, and 5 will be used for the first PWM cycle if current sensing is selected.

NOTE:

If the LDOK bit is not set when PWMEN is set after a RESET, the prescaler and PWM values will be zero, but the modulus will be unknown. If the LDOK bit is not set after the PWMEN bit has been cleared then set (without a RESET), the modulus value that was last loaded will be used.

If the dead-time register (DEADTM) is changed after PWMEN or OUTCTL is set, an improper dead-time insertion could occur. However, the dead time can never be shorter than the specified value.

Because of the equals-comparator architecture of this PWM, the modulus = 0 case is considered illegal. Therefore, the modulus register is not reset, and a modulus value of zero will result in waveforms inconsistent with the other modulus waveforms. See 9.11.2 PWM Counter Modulo Registers.

When PWMEN is set, the PWM pins change from hi-Z to outputs. At this time, assuming no fault condition is present, the PWM pins will drive according to the PWM values, polarity, and dead-time. If the prescaler bits PRSC1:PRSC0 equal 00 (the default condition), the PWM pins will drive on the next CPU clock cycle, as shown by the timing diagram in Figure 9-39.

**NOTE:** 

The timing diagram in **Figure 9-39** is only applicable when PRSC1:PRSC0 = 00. If set to any other value, the PWM outputs will remain in the high-impedance condition for one complete PWM cycle before being driven.

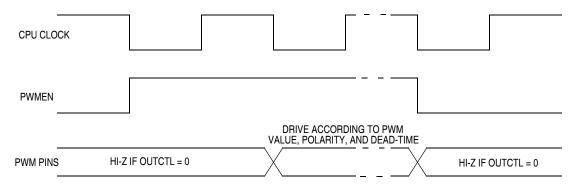

Figure 9-39. PWMEN and PWM Pins

When the PWMEN bit is cleared, the following will occur:

- PWM pins will be tri-stated unless OUTCTL = 1
- PWM counter is cleared and will not be clocked
- Internally, the PWM generator will force its outputs to zero (to avoid glitches when the PWMEN is set again)

When PWMEN is cleared, the following features remain active:

- All fault circuitry
- Manual PWM pin control via the PWMOUT register
- Dead-time insertion when PWM pins change via the PWMOUT register

**NOTE:** The PWMF flag and pending CPU interrupts are NOT cleared when PWMEN = 0.

### 9.9 PWM Operation in Wait Mode

When the microcontroller is put in low-power wait mode via the WAIT instruction, all clocks to the PWM module will continue to run. If an interrupt is issued from the PWM module (via a reload or a fault), the microcontroller will exit wait mode.

Clearing the PWMEN bit before entering wait mode will reduce power consumption in wait mode because the counter, prescaler divider, and LDFQ divider will no longer be clocked. In addition, power will be reduced because the PWMs will no longer toggle.

### 9.10 PWM Operation in Break Mode

If the microcontroller goes into break mode (or background mode), the clocks to the PWM generator and output control blocks will freeze. This allows the user to set a breakpoint on a development system and examine the register contents and PWM outputs at that point. It also allows the user to single-step through the code.

The clocks to the fault block will continue to run. Therefore, if a fault occurs while the microcontroller is in break mode, the PWM outputs will immediately be driven to their inactive state(s).

During break mode, the system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. (See 7.7.4 SIM Break Flag Control Register.)

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the PWMF and FFLAGx bits during the break state, make sure BCFE is a logic 0. With BCFE at logic 0 (its default state), software can read and write the status and control registers during the break state without affecting the PWMF and FFLAGx bits.

MC68HC708MP16 — Rev. 3.1

# 9.11 Control Logic Block

The following subsections provide a description of the control logic block.

### 9.11.1 PWM Counter Registers

This PWM counter register displays the 12-bit up/down or up-only counter. When the high byte of the counter is read, the lower byte is latched. PCNTL will hold this latched value until it is read.

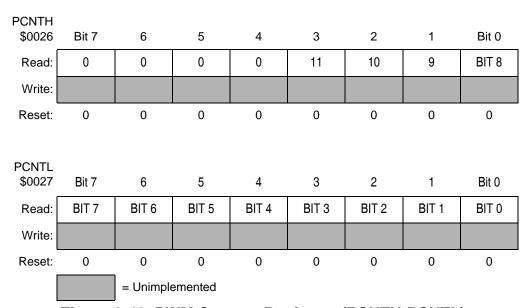

Figure 9-40. PWM Counter Registers (PCNTH:PCNTL)

#### 9.11.2 PWM Counter Modulo Registers

This PWM counter modulus register holds a 12-bit unsigned number that determines the maximum count for the up/down or up-only counter. In center-aligned mode, the PWM period will be twice the modulus (assuming no prescaler). In edge-aligned mode, the PWM period will equal the modulus.

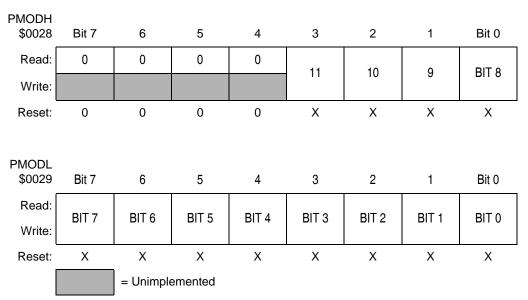

Figure 9-41. PWM Counter Modulo Registers (PDMODH:PMODL)

To avoid erroneous PWM periods, this value is buffered and will not be used by the PWM generator until the LDOK bit has been set and the next PWM load cycle begins.

**NOTE:** When reading this register, the value read is the buffer (not necessarily the value the PWM generator is currently using).

CAUTION:

The user is responsible for initializing the PWM counter modulo registers before enabling the PWM module. Since these registers are undefined at reset, they could contain a combined value of \$0000, which would result in erroneous pulse widths. However, the dead-time constraints will still be guaranteed, and the fault detection circuitry will still function properly.

MC68HC708MP16 — Rev. 3.1

#### 9.11.3 PWM X Value Registers

Each of the six PWMs has a 16-bit PWM value register.

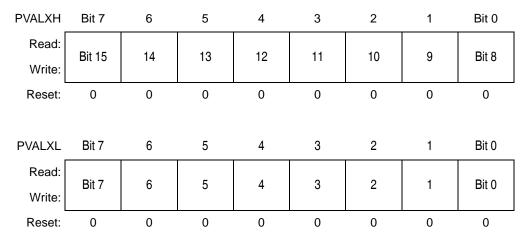

Figure 9-42. PWM X Value Registers (PVALXH:PVALXL)

The 16-bit signed value stored in this register determines the duty cycle of the PWM. The duty cycle is defined as: (PWM value/modulus) x 100.

Writing a number less than or equal to zero causes the PWM to be off for the entire PWM period. Writing a number greater than or equal to the 12-bit modulus causes the PWM to be on for the entire PWM period.

If the complementary mode is selected, the PWM pairs share PWM value registers.

To avoid erroneous PWM pulses, this value is buffered and will not be used by the PWM generator until the LDOK bit has been set and the next PWM load cycle begins.

**NOTE:** When reading these registers, the value read is the buffer (not necessarily the value the PWM generator is currently using).

#### 9.11.4 PWM Control Register 1

PWM control register 1 controls PWM enabling/disabling, the loading of new modulus, prescaler, and PWM values, and the PWM correction method. In addition, this register contains the software disable bits to force the PWM outputs to their inactive states (according to the disable mapping register).

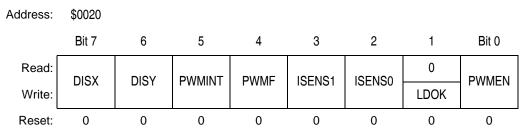

Figure 9-43. PWM Control Register 1 (PCTL1)

#### PWMEN — PWM Module Enable

This read/write bit enables and disables the PWM generator and the PWM pins. When PWMEN is clear, the PWM generator is disabled and the PWM pins are in the high-impedance state (unless OUTCTL = 1).

When the PWMEN bit is set, the PWM generator and PWM pins are activated.

For more information, see **9.8 Initialization and the PWMEN Bit**.

- 1 = PWM generator and PWM pins enabled
- 0 = PWM generator and PWM pins disabled

#### LDOK— Load OK

This write-only bit allows the counter modulus, counter prescaler, and PWM values in the buffered registers to be used by the PWM generator. These values will not be used until the LDOK bit is set and a new PWM load cycle begins. Internally this bit is automatically cleared after the new values are loaded (however, this bit always reads zero).

- 1 = Okay to load new modulus, prescaler, and PWM values at beginning of next PWM load cycle
- 0 = Not okay to load new modulus, prescaler, and PWM values

MC68HC708MP16 - Rev. 3.1

**NOTE:** The user should initialize the PWM registers and set the LDOK bit before enabling the PWM.

A PWM CPU interrupt request can still be generated when LDOK is zero.

ISENS1:ISENS0 — Current Sense Correction Bits

These read/write bits select the top/bottom correction scheme as shown in **Table 9-8**.

Current Correction Bits ISENS1:ISENS0

O0 01

Bits IPOL1, IPOL2, and IPOL3 used for correction

Current sensing on pins IS1, IS2, and IS3 occurs during the dead-time.

Current sensing on pins IS1, IS2, and IS3 occurs at the half cycle in center-aligned mode and at the end of the cycle in edge-aligned mode.

**Table 9-8. Correction Methods** 

#### PWMF— PWM Reload Flag

This read/write bit is set at the beginning of every reload cycle regardless of the state of the LDOK bit. This bit is cleared by reading PWM control register 1 with the PWMF flag set, then writing a logic 0 to PWMF. If another reload occurs before the clearing sequence is complete, then writing logic 0 to PWMF has no effect.

- 1 = New reload cycle began
- 0 = New reload cycle has not begun

**NOTE:** When PWMF is cleared, pending PWM CPU interrupts are cleared (not including fault interrupts).

PWMINT — PWM Interrupt Enable

This read/write bit allows the user to enable and disable PWM CPU interrupts. If set, a CPU interrupt will be pending when the PWMF flag is set.

- 1 = Enable PWM CPU interrupts
- 0 = Disable PWM CPU interrupts

**NOTE:** When PWMINT is cleared, pending CPU interrupts are inhibited.

DISX — Software Disable for Bank X

This read/write bit allows the user to disable one or more PWM pins in bank X. The pins that are disabled are determined by the disable mapping write-once register.

- 1 = Disable PWM pins in bank X
- 0 = Re-enable PWM pins at beginning of next PWM cycle

DISY — Software Disable for Bank Y

This read/write bit allows the user to disable one or more PWM pins in bank Y. The pins that are disabled are determined by the disable mapping write-once register.

- 1 = Disable PWM pins in bank Y
- 0 = Re-enable PWM pins at beginning of next PWM cycle

#### 9.11.5 PWM Control Register 2

PWM control register 2 controls the PWM load frequency, the PWM correction method, and the PWM counter prescaler. For ease of software and to avoid erroneous PWM periods, some of these register bits are buffered. The PWM generator will not use the prescaler value until the LDOK bit has been set, and a new PWM cycle is starting. The correction bits are used at the beginning of each PWM cycle (if the ISENSx bits are configured for software correction). The load frequency bits are not used until the current load cycle is complete.

**NOTE:** The user should initialize this register before enabling the PWM.

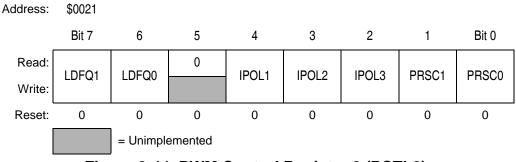

Figure 9-44. PWM Control Register 2 (PCTL2)

MC68HC708MP16 — Rev. 3.1

LDFQ1:LDFQ0 — PWM Load Frequency Bits

These buffered read/write bits select the PWM CPU load frequency according to **Table 9-9**.

**NOTE:** When reading these bits, the value read is the buffer value (not necessarily the value the PWM generator is currently using).

Table 9-9. PWM Reload Frequency

Reload Frequency Bits LDFQ1:LDFQ0	PWM Reload Frequency
00	Every PWM cycle
01	Every 2 PWM cycles
10	Every 4 PWM cycles
11	Every 8 PWM cycles

IPOL1 — Top/Bottom Correction Bit for PWM Pair 1 (PWMs 1 and 2)

This buffered read/write bit selects which PWM value register is used if top/bottom correction is to be achieved without current sensing.

1 = Use PWM value register 2

0 = Use PWM value register 1

**NOTE:** When reading this bit, the value read is the buffer value (not necessarily the value the output control block is currently using).

IPOL2 — Top/Bottom Correction Bit for PWM Pair 2 (PWMs 3 and 4)

This buffered read/write bit selects which PWM value register is used if top/bottom correction is to be achieved without current sensing.

1 = Use PWM value register 4

0 = Use PWM value register 3

**NOTE:** When reading this bit, the value read is the buffer value (not necessarily the value the output control block is currently using).

IPOL3 — Top/Bottom Correction Bit for PWM Pair 3 (PWMs 5 and 6)

This buffered read/write bit selects which PWM value register is used if top/bottom correction is to be achieved without current sensing.

1 = Use PWM value register 6

0 = Use PWM value register 5

**NOTE:** When reading this bit, the value read is the buffer value (not necessarily the value the output control block is currently using).

PRSC1:PRSC0 — PWM Prescaler Bits

These buffered read/write bits allow the PWM clock frequency to be modified as shown in **Table 9-10**.

**NOTE:** When reading these bits, the value read is the buffer value (not necessarily the value the PWM generator is currently using).

Prescaler Bits PRSC1:PRSC0	PWM Clock Frequency
00	f <sub>op</sub>
01	f <sub>op</sub> /2
10	f <sub>op</sub> /4
11	f <sub>op</sub> /8

Table 9-10. PWM Prescaler

### 9.11.6 Dead-Time Write-Once Register

This write-once register holds an 8-bit value which specifies the number of CPU clock cycles to use for the dead-time when complementary PWM mode is selected. After this register is written for the first time, it cannot be rewritten unless a RESET occurs. The dead-time is not affected by changes to the prescaler value.

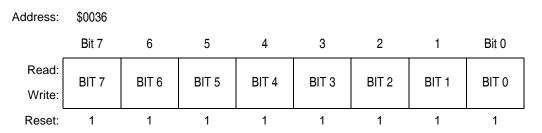

Figure 9-45. Dead-Time Write-Once Register (DEADTM)

### 9.11.7 PWM Disable Mapping Write-Once Register

This write-once register holds an 8-bit value which determines which PWM pins will be disabled if an external fault or software disable occur. For a further description of the disable mapping, see **9.7 Fault**Protection. After this register is written for the first time, it cannot be rewritten unless a RESET occurs.

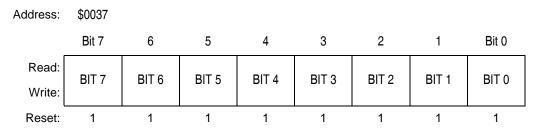

Figure 9-46. PWM Disable Mapping Write-Once Register (DISMAP)

#### 9.11.8 Fault Control Register

This register controls the fault protection circuitry.

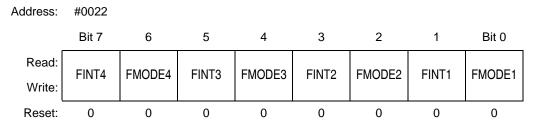

Figure 9-47. Fault Control Register (FCR)

FMODE1 — Fault Mode Selection for Fault Pin 1 (Automatic versus Manual Mode)

This read/write bit allows the user to select between automatic and manual mode faults. For further description of each mode, see **9.7**Fault Protection.

1 = Automatic mode

0 = Manual mode

### FINT1 — Fault 1 Interrupt Enable

This read/write bit allows the CPU interrupt caused by faults on fault pin 1 to be enabled. The fault protection circuitry is independent of this bit and will always be active. If a fault is detected, the PWM pins will still be disabled according to the disable mapping register.

- 1 = Fault pin 1 will cause CPU interrupts
- 0 = Fault pin 1 will not cause CPU interrupts

FMODE2 — Fault Mode Selection for Fault Pin 2 (Automatic versus Manual Mode)

This read/write bit allows the user to select between automatic and manual mode faults. For further description of each mode, see 9.7 Fault Protection.

- 1 = Automatic mode
- 0 = Manual mode

### FINT2 — Fault 2 Interrupt Enable

This read/write bit allows the CPU interrupt caused by faults on fault pin 2 to be enabled. The fault protection circuitry is independent of this bit and will always be active. If a fault is detected, the PWM pins will still be disabled according to the disable mapping register.

- 1 = Fault pin 2 will cause CPU interrupts
- 0 = Fault pin 2 will not cause CPU interrupts

FMODE3 — Fault Mode Selection for Fault Pin 3 (Automatic versus Manual Mode)

This read/write bit allows the user to select between automatic and manual mode faults. For further description of each mode, see 9.7 Fault Protection.

- 1 = Automatic mode
- 0 = Manual mode

# **Pulse Width Modulator for Motor Control (PWMMC)**

### FINT3 — Fault 3 Interrupt Enable

This read/write bit allows the CPU interrupt caused by faults on fault pin 3 to be enabled. The fault protection circuitry is independent of this bit and will always be active. If a fault is detected, the PWM pins will still be disabled according to the disable mapping register.

- 1 = Fault pin 3 will cause CPU interrupts
- 0 = Fault pin 3 will not cause CPU interrupts

FMODE4 — Fault Mode Selection for Fault Pin 4 (Automatic versus Manual Mode)

This read/write bit allows the user to select between automatic and manual mode faults. For further description of each mode, see 9.7 Fault Protection.

- 1 = Automatic mode
- 0 = Manual mode

### FINT4 — Fault 4 Interrupt Enable

This read/write bit allows the CPU interrupt caused by faults on fault pin 4 to be enabled. The fault protection circuitry is independent of this bit and will always be active. If a fault is detected, the PWM pins will still be disabled according to the disable mapping register.

- 1 = Fault pin 4 will cause CPU interrupts
- 0 = Fault pin 4 will not cause CPU interrupts

### 9.11.9 Fault Status Register

This read-only register indicates the current fault status.

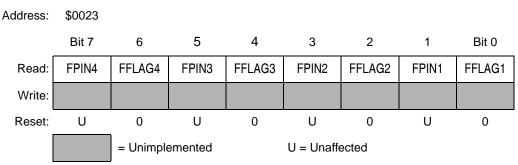

Figure 9-48. Fault Status Register (FSR)

### FFLAG1 — Fault Event Flag 1

The FFLAG1 event bit is set within two CPU cycles after a rising edge on fault pin 1. To clear the FFLAG1 bit, the user must write a 1 to the FTACK1 bit in the fault acknowledge register.

- 1 = A fault has occurred on fault pin 1
- 0 = No new fault on fault pin 1

### FPIN1 — State of Fault Pin 1

This read-only bit allows the user to read the current state of fault pin 1.

- 1 = Fault pin 1 is at logic 1
- 0 = Fault pin 1 is at logic 0

### FFLAG2 — Fault Event Flag 2

The FFLAG2 event bit is set within two CPU cycles after a rising edge on fault pin 2. To clear the FFLAG2 bit, the user must write a 1 to the FTACK2 bit in the fault acknowledge register.

- 1 = A fault has occurred on fault pin 2
- 0 = No new fault on fault pin 2

#### FPIN2 — State of Fault Pin 2

This read-only bit allows the user to read the current state of fault pin 2.

- 1 = Fault pin 2 is at logic 1
- 0 = Fault pin 2 is at logic 0

MC68HC708MP16 — Rev. 3.1

# **Pulse Width Modulator for Motor Control (PWMMC)**

### FFLAG3 — Fault Event Flag 3

The FFLAG3 event bit is set within two CPU cycles after a rising edge on fault pin 3. To clear the FFLAG3 bit, the user must write a 1 to the FTACK3 bit in the fault acknowledge register.

- 1 = A fault has occurred on fault pin 3
- 0 = No new fault on fault pin 3

#### FPIN3 — State of Fault Pin 3

This read-only bit allows the user to read the current state of fault pin 3.

- 1 = Fault pin 3 is at logic 1
- 0 = Fault pin 3 is at logic 0

### FFLAG4 — Fault Event Flag 4

The FFLAG4 event bit is set within two CPU cycles after a rising edge on fault pin 4. To clear the FFLAG4 bit, the user must write a 1 to the FTACK4 bit in the fault acknowledge register.

- 1 = A fault has occurred on fault pin 4
- 0 = No new fault on fault pin 4

### FPIN4 — State of Fault Pin 4

This read-only bit allows the user to read the current state of fault pin 4.

- 1 = Fault pin 4 is at logic 1
- 0 = Fault pin 4 is at logic 0

### 9.11.10 Fault Acknowledge Register

This register is used to acknowledge and clear the FFLAGs. In addition, it is used to monitor the current sensing bits to test proper operation.

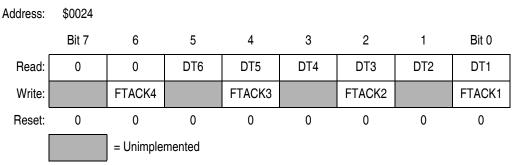

Figure 9-49. Fault Acknowledge Register (FTACK)

### FTACK1 — Fault Acknowledge 1

The FTACK1 bit is used to acknowledge and clear FFLAG1. This bit will always read 0. Writing a 1 to this bit will clear FFLAG1. Writing a 0 will have no effect.

### FTACK2 — Fault Acknowledge 2

The FTACK2 bit is used to acknowledge and clear FFLAG2. This bit will always read 0. Writing a 1 to this bit will clear FFLAG2. Writing a 0 will have no effect.

### FTACK3 — Fault Acknowledge 3

The FTACK3 bit is used to acknowledge and clear FFLAG3. This bit will always read 0. Writing a 1 to this bit will clear FFLAG3. Writing a 0 will have no effect.

### FTACK4 — Fault Acknowledge 4

The FTACK4 bit is used to acknowledge and clear FFLAG4. This bit will always read 0. Writing a 1 to this bit will clear FFLAG4. Writing a 0 will have no effect.

### DT1 — Dead Time 1

Current sensing pin IS1 is monitored immediately before dead time ends due to the assertion of PWM1.

MC68HC708MP16 — Rev. 3.1

### Pulse Width Modulator for Motor Control (PWMMC)

#### DT1 — Dead Time 2

Current sensing pin IS1 is monitored immediately before dead time ends due to the assertion of PWM2.

#### DT1 — Dead Time 3

Current sensing pin IS2 is monitored immediately before dead time ends due to the assertion of PWM3.

#### DT1 — Dead Time 4

Current sensing pin IS2 is monitored immediately before dead time ends due to the assertion of PWM4.

#### DT1 — Dead Time 5

Current sensing pin IS3 is monitored immediately before dead time ends due to the assertion of PWM5.

### DT1 — Dead Time 6

Current sensing pin IS3 is monitored immediately before dead time ends due to the assertion of PWM6.

### 9.11.11 PWM Output Control Register

This register is used to manually control the PWM pins.

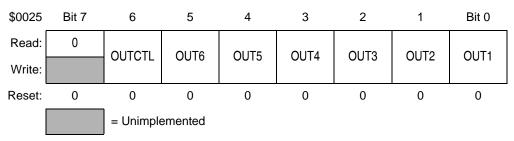

Figure 9-50. PWM Output Control Register (PWMOUT)

### **OUTCTL**— Output Control Enable

This read/write bit allows the user to manually control the PWM pins. When set, the PWM generator is no longer the input to the dead-time and output circuitry. The OUTx bits determine the state of the PWM pins. Setting the OUTCTL bit does not disable the PWM generator.

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

The generator continues to run, but is no longer the input to the PWM dead-time and output circuitry. When OUTCTL is cleared, the outputs of the PWM generator immediately become the inputs to the dead-time and output circuitry.

- 1 = PWM outputs controlled manually
- 0 = PWM outputs determined by PWM generator

### OUT6:OUT1— PWM Pin Output Control Bits

These read/write bits control the PWM pins according to Table 9-11.

Table 9-11. OUTx Bits

OUTx Bit	Complementary Mode	Independent Mode
OUT1	1 — PWM1 is active 0 — PWM1 is inactive	1 — PWM1 is active 0 — PWM1 is inactive
OUT2	1 — PWM2 is complement of PWM 1 0 — PWM2 is inactive	1 — PWM2 is active 0 — PWM2 is inactive
OUT3	1 — PWM3 is active 0 — PWM3 is inactive	1 — PWM3 is active 0 — PWM3 is inactive
OUT4	1 — PWM4 is complement of PWM 3 0 — PWM4 is inactive	1 — PWM4 is active 0 — PWM4 is inactive
OUT5	1 — PWM5 is active 0 — PWM5 is inactive	1 — PWM5 is active 0 — PWM5 is inactive
OUT6	1 — PWM 6 is complement of PWM 5 0 — PWM6 is inactive	1 — PWM6 is active 0 — PWM6 is inactive

### 10.2 Introduction

This section describes the monitor ROM (MON08, Version B). The monitor ROM allows complete testing of the MCU through a single-wire interface with a host computer.

MC68HC708MP16 - Rev. 3.1

### 10.3 Features

Features of the monitor ROM include the following:

- Normal user-mode pin functionality
- One pin dedicated to serial communication between monitor ROM and host computer
- Standard mark/space non-return-to-zero (NRZ) communication with host computer
- 4800 baud–28.8 kbaud communication with host computer
- Execution of code in RAM or ROM
- (E)EPROM/OTPROM programming

### 10.4 Functional Description

The monitor ROM receives and executes commands from a host computer. Figure 10-1 shows a sample circuit used to enter monitor mode and communicate with a host computer via a standard RS-232 interface.

Simple monitor commands can access any memory address. In monitor mode, the MCU can execute host-computer code in RAM while all MCU pins retain normal operating mode functions. All communication between the host computer and the MCU is through the PTA0 pin. A level-shifting and multiplexing interface is required between PTA0 and the host computer. PTA0 is used in a wired-OR configuration and requires a pull-up resistor.

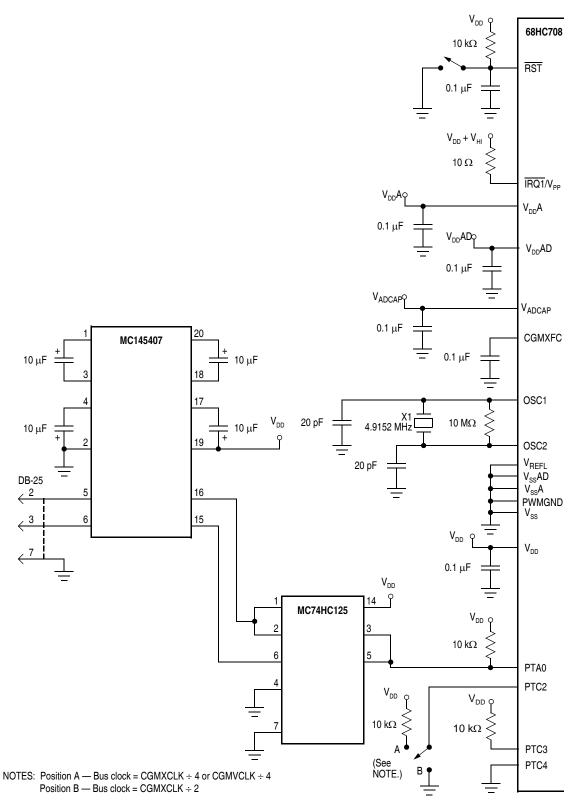

Figure 10-1. Monitor Mode Circuit

MC68HC708MP16 - Rev. 3.1

### 10.4.1 Entering Monitor Mode

**Table 10-1** shows the pin conditions for entering monitor mode.

RQ1/V<sub>PP</sub> Pin PTC3 Pin PTC4 Pin PTA0 Pin PTC2 Pin Bus Mode CGMOUT Frequency CGMXCLK or CGMVCLK **CGMOUT** 0 Monitor  $V_{DD} + V_{HI}$ 1 1 **CGMOUT**  $V_{DD} + V_{HI}$ 0 1 0 Monitor **CGMXCLK** 

Table 10-1. Mode Selection

Enter monitor mode by either:

- · Executing a software interrupt instruction (SWI) or
- Applying a logic 0 and then a logic 1 to the RST pin.

The MCU sends a break signal (10 consecutive logic 0s) to the host computer, indicating that it is ready to receive a command. The break signal also provides a timing reference to allow the host to determine the necessary baud rate.

Monitor mode uses alternate vectors for reset, SWI, and break interrupt. The alternate vectors are in the \$FE page instead of the \$FF page and allow code execution from the internal monitor firmware instead of user code. The COP module is disabled in monitor mode as long as  $V_{DD} + V_{HI}$  is applied to either the  $\overline{IRQ1}/V_{PP}$  pin or the  $\overline{RST}$  pin. (See Section 7. System Integration Module (SIM) for more information on modes of operation.)

**NOTE:** 

Holding the PTC2 pin low when entering monitor mode causes a bypass of a divide-by-two stage at the oscillator. The CGMOUT frequency is equal to the CGMXCLK frequency, and the OSC1 input directly generates internal bus clocks. In this case, the OSC1 signal must have a 50% duty cycle at maximum bus frequency.

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

**Table 10-2** is a summary of the differences between user mode and monitor mode.

**Table 10-2. Mode Differences** 

	Functions						
Modes	СОР	Reset Vector High	Reset Vector Low	Break Vector High	Break Vector Low	SWI Vector High	SWI Vector Low
User	Enabled	\$FFFE	\$FFFF	\$FFFC	\$FFFD	\$FFFC	\$FFFD
Monitor	Disabled <sup>(1)</sup>	\$FEFE	\$FEFF	\$FEFC	\$FEFD	\$FEFC	\$FEFD

If the high voltage (V<sub>DD</sub> + V<sub>HI</sub>) is removed from the IRQ1/V<sub>PP</sub> pin or the RST pin, the SIM asserts its COP enable output. The COP is a mask option enabled or disabled by the COPD bit in the mask option register.

#### 10.4.2 Data Format

Communication with the monitor ROM is in standard non-return-to-zero (NRZ) mark/space data format. (See Figure 10-2 and Figure 10-3.)

Figure 10-2. Monitor Data Format

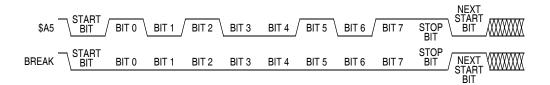

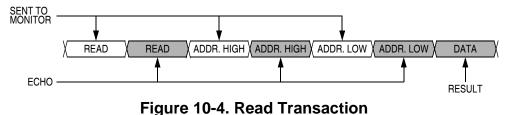

Figure 10-3. Sample Monitor Waveforms

The data transmit and receive rate can be anywhere from 4800 baud to 28.8 kbaud. Transmit and receive baud rates must be identical.

### 10.4.3 Echoing

As shown in **Figure 10-4**, the monitor ROM immediately echoes each received byte back to the PTA0 pin for error checking.

Tigalo to introdu transaction

Any result of a command appears after the echo of the last byte of the command.

### 10.4.4 Break Signal

A start bit followed by nine low bits is a break signal. (See **Figure 10-5**.) When the monitor receives a break signal, it drives the PTA0 pin high for the duration of two bits before echoing the break signal.

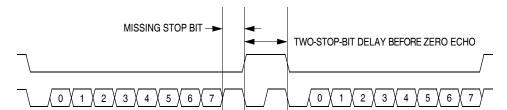

Figure 10-5. Break Transaction

### 10.4.5 Commands

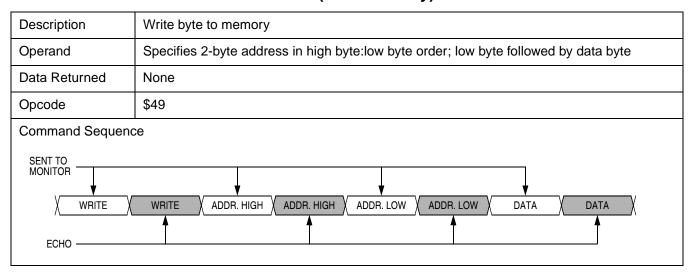

The monitor ROM uses the following commands:

- READ (read memory)
- WRITE (write memory)
- IREAD (indexed read)
- IWRITE (indexed write)
- READSP (read stack pointer)
- RUN (run user program)

### Table 10-3. READ (Read Memory) Command

### 10.4.6 Baud Rate

With a 4.9152-MHz crystal and the PTC2 pin at logic 1 during reset, data is transferred between the monitor and host at 4800 baud. If the PTC2 pin is at logic 0 during reset, the monitor baud rate is 9600. When the CGM output, CGMOUT, is driven by the PLL, the baud rate is determined by the MUL[7:4] bits in the PLL programming register (PPG). (See Section 8. Clock Generator Module (CGM).)

**Table 10-9. Monitor Baud Rate Selection** 

	VCO Frequency Multiplier (N)					
	1	2	3	4	5	6
Monitor Baud Rate	4800	9600	14,400	19,200	24,000	28,800

### 11.2 Introduction

This section describes the timer interface module (TIM2, Version B). The TIMA is a two-channel timer that provides a timing reference with input capture, output compare, and pulse-width-modulation functions. **Figure 11-1** is a block diagram of the TIM.

**NOTE:** 

Timer interface module A (TIMA) is only available in the 64-pin quad flat package.

### 11.3 Features

Features of the TIMA include the following:

- Two input capture/output compare channels
  - Rising-edge, falling-edge, or any-edge input capture trigger
  - Set, clear, or toggle output compare action
- Buffered and unbuffered pulse width modulation (PWM) signal generation
- Programmable TIMA clock input
  - Seven-frequency internal bus clock prescaler selection
  - External TIMA clock input (4-MHz maximum frequency)
- Free-running or modulo up-count operation
- Toggle any channel pin on overflow
- TIMA counter stop and reset bits
- Modular architecture expandable to eight channels

# 11.4 Functional Description

**Figure 11-1** shows the structure of the TIMA. The central component of the TIMA is the 16-bit TIMA counter that can operate as a free-running counter or a modulo up-counter. The TIMA counter provides the timing reference for the input capture and output compare functions. The TIMA counter modulo registers, TAMODH:TAMODL, control the modulo value

of the TIMA counter. Software can read the TIMA counter value at any time without affecting the counting sequence.

The two TIMA channels are programmable independently as input capture or output compare channels.

Figure 11-2. TIMA I/O Register Summary

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

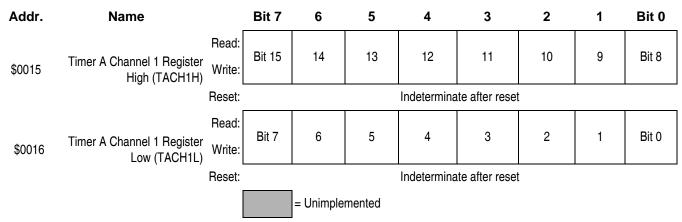

Figure 11-2. TIMA I/O Register Summary (Continued)

#### 11.4.1 TIMA Counter Prescaler

The TIMA clock source can be one of the seven prescaler outputs or the TIMA clock pin, PTE0/TCLKA. The prescaler generates seven clock rates from the internal bus clock. The prescaler select bits, PS[2:0], in the TIMA status and control register select the TIMA clock source.

### 11.4.2 Input Capture

With the input capture function, the TIMA can capture the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the TIMA latches the contents of the TIMA counter into the TIMA channel registers, TACHxH:TACHxL. The polarity of the active edge is programmable. Input captures can generate TIM CPU interrupt requests.

### 11.4.3 Output Compare

With the output compare function, the TIMA can generate a periodic pulse with a programmable polarity, duration, and frequency. When the counter reaches the value in the registers of an output compare channel, the TIMA can set, clear, or toggle the channel pin. Output compares can generate TIM CPU interrupt requests.

MC68HC708MP16 — Rev. 3.1

### 11.4.3.1 Unbuffered Output Compare

Any output compare channel can generate unbuffered output compare pulses as described in **11.4.3 Output Compare**. The pulses are unbuffered because changing the output compare value requires writing the new value over the old value currently in the TIMA channel registers.

An unsynchronized write to the TIMA channel registers to change an output compare value could cause incorrect operation for up to two counter overflow periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that counter overflow period. Also, using a TIMA overflow interrupt routine to write a new, smaller output compare value may cause the compare to be missed. The TIMA may pass the new value before it is written.

Use the following methods to synchronize unbuffered changes in the output compare value on channel x:

- When changing to a smaller value, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current output compare pulse. The interrupt routine has until the end of the counter overflow period to write the new value.
- When changing to a larger output compare value, enable channel x TIMA overflow interrupts and write the new value in the TIMA overflow interrupt routine. The TIMA overflow interrupt occurs at the end of the current counter overflow period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same counter overflow period.

### 11.4.3.2 Buffered Output Compare

Channels 0 and 1 can be linked to form a buffered output compare channel whose output appears on the PTE1/TCH0A pin. The TIMA channel registers of the linked pair alternately control the output.

Setting the MS0B bit in TIMA channel 0 status and control register (TASC0) links channel 0 and channel 1. The output compare value in the TIMA channel 0 registers initially controls the output on the PTE1/TCH0A pin. Writing to the TIMA channel 1 registers enables the TIMA channel 1 registers to synchronously control the output after the TIMA overflows. At each subsequent overflow, the TIMA channel registers (0 or 1) that control the output are the ones written to last. TASC0 controls and monitors the buffered output compare function, and TIMA channel 1 status and control register (TASC1) is unused. While the MS0B bit is set, the channel 1 pin, PTE2/TCH1A, is available as a general-purpose I/O pin.

#### **NOTE:**

In buffered output compare operation, do not write new output compare values to the currently active channel registers. Writing to the active channel registers is the same as generating unbuffered output compares.

### 11.4.4 Pulse Width Modulation (PWM)

By using the toggle-on-overflow feature with an output compare channel, the TIMA can generate a PWM signal. The value in the TIMA counter modulo registers determines the period of the PWM signal. The channel pin toggles when the counter reaches the value in the TIMA counter modulo registers. The time between overflows is the period of the PWM signal.

As **Figure 11-3** shows, the output compare value in the TIMA channel registers determines the pulse width of the PWM signal. The time between overflow and output compare is the pulse width. Program the TIMA to clear the channel pin on output compare if the state of the PWM pulse is logic 1. Program the TIMA to set the pin if the state of the PWM pulse is logic 0.

MC68HC708MP16 — Rev. 3.1

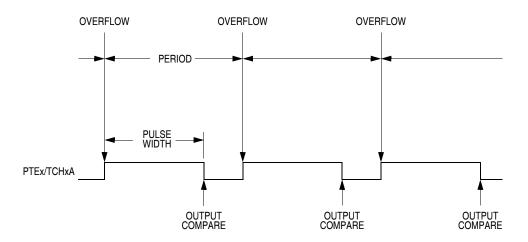

Figure 11-3. PWM Period and Pulse Width

The value in the TIMA counter modulo registers and the selected prescaler output determines the frequency of the PWM output. The frequency of an 8-bit PWM signal is variable in 256 increments. Writing \$00FF (255) to the TIMA counter modulo registers produces a PWM period of 256 times the internal bus clock period if the prescaler select value is 000 (see 11.9.1 TIMA Status and Control Register).

The value in the TIMA channel registers determines the pulse width of the PWM output. The pulse width of an 8-bit PWM signal is variable in 256 increments. Writing \$0080 (128) to the TIMA channel registers produces a duty cycle of 128/256 or 50%.

### 11.4.4.1 Unbuffered PWM Signal Generation

Any output compare channel can generate unbuffered PWM pulses as described in 11.4.4 Pulse Width Modulation (PWM). The pulses are unbuffered because changing the pulse width requires writing the new pulse width value over the old value currently in the TIMA channel registers.

An unsynchronized write to the TIMA channel registers to change a pulse width value could cause incorrect operation for up to two PWM periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that PWM period. Also, using a TIMA overflow interrupt routine to write a new, smaller pulse width value may cause the compare to be missed. The TIMA may pass the new value before it is written.

Use the following methods to synchronize unbuffered changes in the PWM pulse width on channel x:

- When changing to a shorter pulse width, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current pulse. The interrupt routine has until the end of the PWM period to write the new value.
- When changing to a longer pulse width, enable channel x TIMA overflow interrupts and write the new value in the TIMA overflow interrupt routine. The TIMA overflow interrupt occurs at the end of the current PWM period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same PWM period.

#### **NOTE:**

In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0% duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare also can cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.

MC68HC708MP16 — Rev. 3.1

### 11.4.4.2 Buffered PWM Signal Generation

Channels 0 and 1 can be linked to form a buffered PWM channel whose output appears on the PTE1/TCH0A pin. The TIMA channel registers of the linked pair alternately control the pulse width of the output.

Setting the MS0B bit in TIMA channel 0 status and control register (TASC0) links channel 0 and channel 1. The TIMA channel 0 registers initially control the pulse width on the PTE1/TCH0A pin. Writing to the TIMA channel 1 registers enables the TIMA channel 1 registers to synchronously control the pulse width at the beginning of the next PWM period. At each subsequent overflow, the TIMA channel registers (0 or 1) that control the pulse width are the ones written to last. TASC0 controls and monitors the buffered PWM function, and TIMA channel 1 status and control register (TASC1) is unused. While the MS0B bit is set, the channel 1 pin, PTE2/TCH1A, is available as a general-purpose I/O pin.

**NOTE:** 

In buffered PWM signal generation, do not write new pulse width values to the currently active channel registers. Writing to the active channel registers is the same as generating unbuffered PWM signals.

#### 11.4.4.3 PWM Initialization

To ensure correct operation when generating unbuffered or buffered PWM signals, use the following initialization procedure:

- 1. In the TIMA status and control register (TASC):
  - a. Stop the TIMA counter by setting the TIMA stop bit, TSTOP.
  - b. Reset the TIMA counter by setting the TIMA reset bit, TRST.
- 2. In the TIMA counter modulo registers (TAMODH:TAMODL), write the value for the required PWM period.
- 3. In the TIMA channel x registers (TACHxH:TACHxL), write the value for the required pulse width.

- 4. In TIMA channel x status and control register (TASCx):
  - a. Write 0:1 (for unbuffered output compare or PWM signals) or
     1:0 (for buffered output compare or PWM signals) to the mode select bits, MSxB:MSxA. (See Table 11-2.)
  - b. Write 1 to the toggle-on-overflow bit, TOVx.
  - c. Write 1:0 (to clear output on compare) or 1:1 (to set output on compare) to the edge/level select bits, ELSxB:ELSxA. The output action on compare must force the output to the complement of the pulse width level. (See Table 11-2.)

#### NOTE:

In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0% duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare can also cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.

5. In the TIMA status control register (TASC), clear the TIMA stop bit, TSTOP.

Setting MS0B links channels 0 and 1 and configures them for buffered PWM operation. The TIMA channel 0 registers (TACH0H:TACH0L) initially control the buffered PWM output. TIMA status control register 0 (TASCR0) controls and monitors the PWM signal from the linked channels. MS0B takes priority over MS0A.

Clearing the toggle-on-overflow bit, TOVx, inhibits output toggles on TIMA overflows. Subsequent output compares try to force the output to a state it is already in and have no effect. The result is a 0% duty cycle output.

Setting the channel x maximum duty cycle bit (CHxMAX) and clearing the TOVx bit generates a 100% duty cycle output. (See 11.9.4 TIMA Channel Status and Control Registers.)

### 11.5 Interrupts

The following TIMA sources can generate interrupt requests:

- TIMA overflow flag (TOF) The TOF bit is set when the TIMA counter value rolls over to \$0000 after matching the value in the TIMA counter modulo registers. The TIMA overflow interrupt enable bit, TOIE, enables TIMA overflow CPU interrupt requests. TOF and TOIE are in the TIMA status and control register.
- TIMA channel flags (CH1F:CH0F) The CHxF bit is set when an input capture or output compare occurs on channel x. Channel x TIM CPU interrupt requests are controlled by the channel x interrupt enable bit, CHxIE. Channel x TIM CPU interrupt requests are enabled when CHxIE = 1. CHxF and CHxIE are in the TIMA channel x status and control register.

### 11.6 Wait Mode

The WAIT instruction puts the MCU in low-power-consumption standby mode.

The TIMA remains active after the execution of a WAIT instruction. In wait mode the TIMA registers are not accessible by the CPU. Any enabled CPU interrupt request from the TIMA can bring the MCU out of wait mode.

If TIMA functions are not required during wait mode, reduce power consumption by stopping the TIMA before executing the WAIT instruction.

### 11.7 TIMA During Break Interrupts

A break interrupt stops the TIMA counter.

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. (See 7.7.4 SIM Break Flag Control Register.)

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a two-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

# 11.8 I/O Signals

Port E shares three of its pins with the TIMA. PTE0/TCLKA is an external clock input to the TIMA prescaler. The two TIMA channel I/O pins are PTE1/TCH0A and PTE2/TCH1A.

#### 11.8.1 TIMA Clock Pin (PTEO/TCLKA)

PTE0/TCLKA is an external clock input that can be the clock source for the TIMA counter instead of the prescaled internal bus clock. Select the PTE0/TCLKA input by writing logic 1s to the three prescaler select bits,

MC68HC708MP16 — Rev. 3.1

PS[2:0]. (See 11.9.1 TIMA Status and Control Register.) The minimum TCLK pulse width,  $TCLK_{LMIN}$  or  $TCLK_{HMIN}$ , is:

$$\frac{1}{\text{bus frequency}} + t_{SU}$$

The maximum TCLK frequency is:

bus frequency ÷ 2

PTE0/TCLKA is available as a general-purpose I/O pin when not used as the TIMA clock input. When the PTE0/TCLKA pin is the TIMA clock input, it is an input regardless of the state of the DDRE0 bit in data direction register E.

### 11.8.2 TIMA Channel I/O Pins (PTE1/TCH0A:PTE2/TCH1A)

Each channel I/O pin is programmable independently as an input capture pin or an output compare pin. PTE1/TCH0A and PTE2/TCH1A can be configured as buffered output compare or buffered PWM pins.

# 11.9 I/O Registers

The following I/O registers control and monitor operation of the TIM:

- TIMA status and control register (TASC)
- TIMA control registers (TACNTH:TACNTL)
- TIMA counter modulo registers (TAMODH:TAMODL)
- TIMA channel status and control registers (TASC0 and TASC1)
- TIMA channel registers (TACH0H:TACH0L and TACH1H:TACH1L)

### 11.9.1 TIMA Status and Control Register

The TIMA status and control register does the following:

- Enables TIMA overflow interrupts
- Flags TIMA overflows
- Stops the TIMA counter
- Resets the TIMA counter
- Prescales the TIMA counter clock

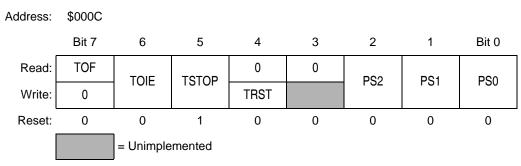

Figure 11-4. TIMA Status and Control Register (TASC)

### TOF — TIMA Overflow Flag Bit

This read/write flag is set when the TIMA counter resets to \$0000 after reaching the modulo value programmed in the TIMA counter modulo registers. Clear TOF by reading the TIMA status and control register when TOF is set and then writing a logic 0 to TOF. If another TIMA overflow occurs before the clearing sequence is complete, then writing logic 0 to TOF has no effect. Therefore, a TOF interrupt request cannot be lost due to inadvertent clearing of TOF. Reset clears the TOF bit. Writing a logic 1 to TOF has no effect.

- 1 = TIMA counter has reached modulo value
- 0 = TIMA counter has not reached modulo value

### TOIE — TIMA Overflow Interrupt Enable Bit

This read/write bit enables TIMA overflow interrupts when the TOF bit becomes set. Reset clears the TOIE bit.

- 1 = TIMA overflow interrupts enabled
- 0 = TIMA overflow interrupts disabled

MC68HC708MP16 — Rev. 3.1

TSTOP — TIMA Stop Bit

This read/write bit stops the TIMA counter. Counting resumes when TSTOP is cleared. Reset sets the TSTOP bit, stopping the TIMA counter until software clears the TSTOP bit.

1 = TIMA counter stopped

0 = TIMA counter active

**NOTE:** Do not set the TSTOP bit before entering wait mode if the TIMA is required to exit wait mode.

TRST — TIMA Reset Bit

Setting this write-only bit resets the TIMA counter and the TIMA prescaler. Setting TRST has no effect on any other registers. Counting resumes from \$0000. TRST is cleared automatically after the TIMA counter is reset and always reads as logic 0. Reset clears the TRST bit.

1 = Prescaler and TIMA counter cleared

0 = No effect

**NOTE:** Setting the TSTOP and TRST bits simultaneously stops the TIMA counter at a value of \$0000.

PS[2:0] — Prescaler Select Bits

These read/write bits select either the PTE0/TCLKA pin or one of the seven prescaler outputs as the input to the TIMA counter as **Table 11-1** shows. Reset clears the PS[2:0] bits.

**Table 11-1. Prescaler Selection** 

PS[2:0]	TIMA Clock Source			
000	Internal Bus Clock ÷1			
001	Internal Bus Clock ÷ 2			
010	Internal Bus Clock ÷ 4			
011	Internal Bus Clock ÷ 8			
100	Internal Bus Clock ÷ 16			
101	Internal Bus Clock ÷ 32			
110	Internal Bus Clock ÷ 64			
111	PTE0/TCLKA			

## 11.9.2 TIMA Counter Registers

The two read-only TIMA counter registers contain the high and low bytes of the value in the TIMA counter. Reading the high byte (TACNTH) latches the contents of the low byte (TACNTL) into a buffer. Subsequent reads of TACNTH do not affect the latched TACNTL value until TACNTL is read. Reset clears the TIMA counter registers. Setting the TIMA reset bit (TRST) also clears the TIMA counter registers.

#### **NOTE:**

If you read TACNTH during a break interrupt, be sure to unlatch TACNTL by reading TACNTL before exiting the break interrupt. Otherwise, TACNTL retains the value latched during the break.

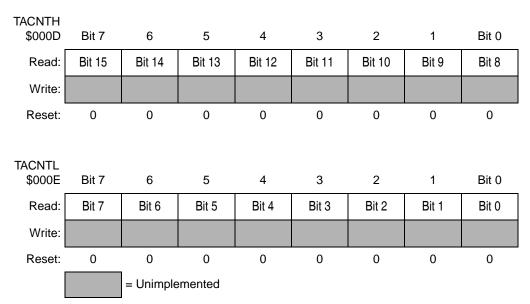

Figure 11-5. TIMA Counter Registers (TACNTH:TACNTL)

#### 11.9.3 TIMA Counter Modulo Registers

The read/write TIMA modulo registers contain the modulo value for the TIMA counter. When the TIMA counter reaches the modulo value, the overflow flag (TOF) becomes set, and the TIMA counter resumes counting from \$0000 at the next clock. Writing to the high byte (TAMODH) inhibits the TOF bit and overflow interrupts until the low byte (TAMODL) is written. Reset sets the TIMA counter modulo registers.

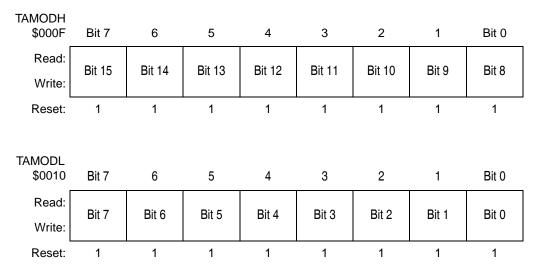

Figure 11-6. TIMA Counter Modulo Registers (TAMODH:TAMODL)

**NOTE:** Reset the TIMA counter before writing to the TIMA counter modulo registers.

#### 11.9.4 TIMA Channel Status and Control Registers

Each of the TIMA channel status and control registers does the following:

- Flags input captures and output compares
- Enables input capture and output compare interrupts
- Selects input capture, output compare, or PWM operation
- Selects high, low, or toggling output on output compare
- Selects rising edge, falling edge, or any edge as the active input capture trigger
- Selects output toggling on TIMA overflow
- Selects 100% PWM duty cycle
- Selects buffered or unbuffered output compare/PWM operation

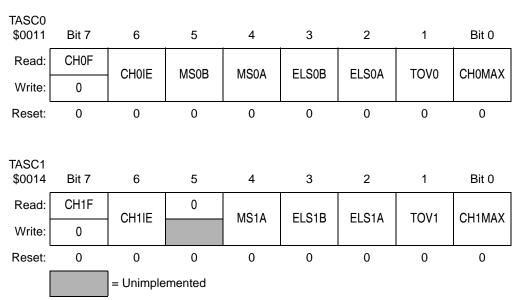

Figure 11-7. TIMA Channel Status and Control Registers (TASC0:TASC1)

## CHxF — Channel x Flag Bit

When channel x is an input capture channel, this read/write bit is set when an active edge occurs on the channel x pin. When channel x is an output compare channel, CHxF is set when the value in the TIMA counter registers matches the value in the TIMA channel x registers.

When TIMA CPU interrupt requests are enabled (CHxIE=1), clear CHxF by reading the TIMA channel x status and control register with CHxF set and then writing a logic 0 to CHxF. If another interrupt request occurs before the clearing sequence is complete, then writing logic 0 to CHxF has no effect. Therefore, an interrupt request cannot be lost due to inadvertent clearing of CHxF.

Reset clears the CHxF bit. Writing a logic 1 to CHxF has no effect.

- 1 = Input capture or output compare on channel x
- 0 = No input capture or output compare on channel x

#### CHxIE — Channel x Interrupt Enable Bit

This read/write bit enables TIMA CPU interrupt service requests on channel x. Reset clears the CHxIE bit.

- 1 = Channel x CPU interrupt requests enabled
- 0 = Channel x CPU interrupt requests disabled

#### MSxB — Mode Select Bit B

This read/write bit selects buffered output compare/PWM operation. MSxB exists only in the TIMA channel 0 status and control register.

Setting MS0B disables the channel 1 status and control register and reverts TCH1 to general-purpose I/O.

Reset clears the MSxB bit.

- 1 = Buffered output compare/PWM operation enabled
- 0 = Buffered output compare/PWM operation disabled

#### MSxA — Mode Select Bit A

When ELSxB:A  $\neq$  00, this read/write bit selects either input capture operation or unbuffered output compare/PWM operation.

See Table 11-2.

- 1 = Unbuffered output compare/PWM operation
- 0 = Input capture operation

When ELSxB:A = 00, this read/write bit selects the initial output level of the TCHx pin. (See Table 11-2.). Reset clears the MSxA bit.

1 = Initial output level low

0 = Initial output level high

NOTE: Before changing a channel function by writing to the MSxB or MSxA bit, set the TSTOP and TRST bits in the TIMA status and control register (TSC).

#### ELSxB and ELSxA — Edge/Level Select Bits

When channel x is an input capture channel, these read/write bits control the active edge-sensing logic on channel x.

When channel x is an output compare channel, ELSxB and ELSxA control the channel x output behavior when an output compare occurs.

When ELSxB and ELSxA are both clear, channel x is not connected to port E, and pin PTEx/TCHxA is available as a general-purpose I/O pin. Table 11-2 shows how ELSxB and ELSxA work. Reset clears the ELSxB and ELSxA bits.

Table 11-2. Mode, Edge, and Level Selection

MSxB:MSxA	ELSxB:ELSxA	Mode	Configuration		
X0	00	Output	Pin under Port Control; Initial Output Level High		
X1	00	Preset	Pin under Port Control; Initial Output Level Low		
00	01	_	Capture on Rising Edge Only		
00	10	Input Capture	Capture on Falling Edge Only		
00	11	o ap tai o	Capture on Rising or Falling Edge		
01	01	Output	Toggle Output on Compare		
01	10	Compare	Clear Output on Compare		
01	11	or PWM	Set Output on Compare		
1X	01	Buffered	Toggle Output on Compare		
1X	10	Output Compare or	Clear Output on Compare		
1X	11	Buffered PWM	Set Output on Compare		

MC68HC708MP16 — Rev. 3.1

**NOTE:** Before enabling a TIMA channel register for input capture operation, make sure that the PTEx/TACHx pin is stable for at least two bus clocks.

TOVx — Toggle-On-Overflow Bit

When channel x is an output compare channel, this read/write bit controls the behavior of the channel x output when the TIMA counter overflows. When channel x is an input capture channel, TOVx has no effect. Reset clears the TOVx bit.

- 1 = Channel x pin toggles on TIMA counter overflow.
- 0 = Channel x pin does not toggle on TIMA counter overflow.

**NOTE:** When TOVx is set, a TIMA counter overflow takes precedence over a channel x output compare if both occur at the same time.

CHxMAX — Channel x Maximum Duty Cycle Bit

When the TOVx bit is at logic 0, setting the CHxMAX bit forces the duty cycle of buffered and unbuffered PWM signals to 100%. As **Figure 11-8** shows, the CHxMAX bit takes effect in the cycle after it is set or cleared. The output stays at the 100% duty cycle level until the cycle after CHxMAX is cleared.

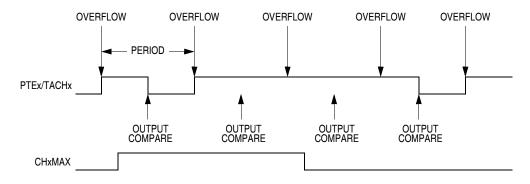

Figure 11-8. CHxMAX Latency

## 11.9.5 TIMA Channel Registers

These read/write registers contain the captured TIMA counter value of the input capture function or the output compare value of the output compare function. The state of the TIMA channel registers after reset is unknown.

In input capture mode (MSxB:MSxA = 0:0), reading the high byte of the TIMA channel x registers (TACHxH) inhibits input captures until the low byte (TACHxL) is read.

In output compare mode (MSxB:MSxA  $\neq$  0:0), writing to the high byte of the TIMA channel x registers (TACHxH) inhibits output compares until the low byte (TACHxL) is written.

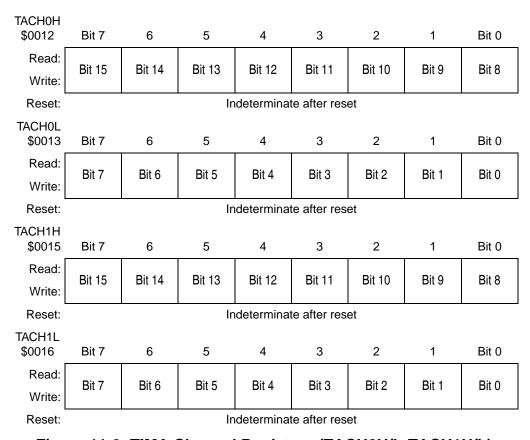

Figure 11-9. TIMA Channel Registers (TACH0H/L:TACH1H/L)

#### 12.2 Introduction

This section describes the timer interface module (TIM4, Version B). The TIMB is a four-channel timer that provides a timing reference with input capture, output compare, and pulse-width-modulation functions.

Figure 12-1 is a block diagram of the TIMB.

#### 12.3 Features

#### Features of the TIMB include:

- Four input capture/output compare channels
  - Rising-edge, falling-edge, or any-edge input capture trigger
  - Set, clear, or toggle output compare action
- Buffered and unbuffered pulse width modulation (PWM) signal generation
- Programmable TIMB clock input
  - Seven-frequency internal bus clock prescaler selection
  - External TIMB clock input (4-MHz maximum frequency)
- Free-running or modulo up-count operation
- Toggle any channel pin on overflow
- TIMB counter stop and reset bits
- Modular architecture expandable to eight channels

## 12.4 Functional Description

Figure 12-1 shows the structure of the TIMB. The central component of the TIMB is the 16-bit TIMB counter that can operate as a free-running counter or a modulo up-counter. The TIMB counter provides the timing reference for the input capture and output compare functions. The TIMB counter modulo registers, TBMODH:TBMODL, control the modulo value of the TIMB counter. Software can read the TIMB counter value at any time without affecting the counting sequence.

The four TIMB channels are programmable independently as input capture or output compare channels.

Figure 12-2. TIMB I/O Register Summary

MC68HC708MP16 — Rev. 3.1

#### 12.4.1 TIMB Counter Prescaler

The TIMB clock source can be one of the seven prescaler outputs or the TIMB clock pin, PTE3/TCLKB. The prescaler generates seven clock rates from the internal bus clock. The prescaler select bits, PS[2:0], in the TIMB status and control register select the TIMB clock source.

#### 12.4.2 Input Capture

With the input capture function, the TIMB can capture the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the TIMB latches the contents of the TIMB counter into the TIMB channel registers, TBCHxH:TBCHxL. The polarity of the active edge is programmable. Input captures can generate TIM CPU interrupt requests.

## 12.4.3 Output Compare

With the output compare function, the TIMB can generate a periodic pulse with a programmable polarity, duration, and frequency. When the counter reaches the value in the registers of an output compare channel, the TIMB can set, clear, or toggle the channel pin. Output compares can generate TIM CPU interrupt requests.

## 12.4.3.1 Unbuffered Output Compare

Any output compare channel can generate unbuffered output compare pulses as described in **12.4.3 Output Compare**. The pulses are unbuffered because changing the output compare value requires writing the new value over the old value currently in the TIMB channel registers.

An unsynchronized write to the TIMB channel registers to change an output compare value could cause incorrect operation for up to two counter overflow periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that counter overflow period. Also, using a TIMB overflow interrupt routine to write a new, smaller output

compare value may cause the compare to be missed. The TIMB may pass the new value before it is written.

Use the following methods to synchronize unbuffered changes in the output compare value on channel x:

- When changing to a smaller value, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current output compare pulse. The interrupt routine has until the end of the counter overflow period to write the new value.
- When changing to a larger output compare value, enable channel x TIMB overflow interrupts and write the new value in the TIMB overflow interrupt routine. The TIMB overflow interrupt occurs at the end of the current counter overflow period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same counter overflow period.

## 12.4.3.2 Buffered Output Compare

Channels 0 and 1 can be linked to form a buffered output compare channel whose output appears on the PTE4/TCH0B pin. The TIMB channel registers of the linked pair alternately control the output.

Setting the MS0B bit in TIMB channel 0 status and control register (TBSC0) links channel 0 and channel 1. The output compare value in the TIMB channel 0 registers initially controls the output on the PTE4/TCH0B pin. Writing to the TIMB channel 1 registers enables the TIMB channel 1 registers to synchronously control the output after the TIMB overflows. At each subsequent overflow, the TIMB channel registers (0 or 1) that control the output are the ones written to last. TBSC0 controls and monitors the buffered output compare function, and TIMB channel 1 status and control register (TBSC1) is unused. While the MS0B bit is set, the channel 1 pin, PTE5/TCH1B, is available as a general-purpose I/O pin.

MC68HC708MP16 — Rev. 3.1

Channels 2 and 3 can be linked to form a buffered output compare channel whose output appears on the PTE6/TCH2B pin. The TIMB channel registers of the linked pair alternately control the output.

Setting the MS2B bit in TIMB channel 2 status and control register (TBSC2) links channel 2 and channel 3. The output compare value in the TIMB channel 2 registers initially controls the output on the PTE6/TCH2B pin. Writing to the TIMB channel 3 registers enables the TIMB channel 3 registers to synchronously control the output after the TIMB overflows. At each subsequent overflow, the TIMB channel registers (2 or 3) that control the output are the ones written to last. TBSC2 controls and monitors the buffered output compare function, and TIMB channel 3 status and control register (TBSC3) is unused. While the MS2B bit is set, the channel 3 pin, PTE7/TCH3B, is available as a general-purpose I/O pin.

#### **NOTE:**

In buffered output compare operation, do not write new output compare values to the currently active channel registers. Writing to the active channel registers is the same as generating unbuffered output compares.

#### 12.4.4 Pulse Width Modulation (PWM)

By using the toggle-on-overflow feature with an output compare channel, the TIMB can generate a PWM signal. The value in the TIMB counter modulo registers determines the period of the PWM signal. The channel pin toggles when the counter reaches the value in the TIMB counter modulo registers. The time between overflows is the period of the PWM signal.

As Figure 12-3 shows, the output compare value in the TIMB channel registers determines the pulse width of the PWM signal. The time between overflow and output compare is the pulse width. Program the TIMB to clear the channel pin on output compare if the state of the PWM pulse is logic 1. Program the TIMB to set the pin if the state of the PWM pulse is logic 0.

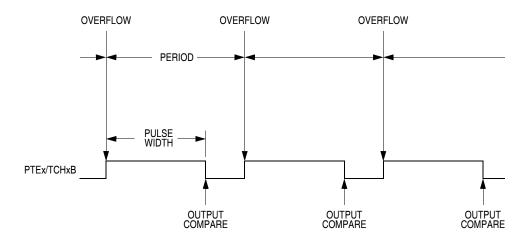

Figure 12-3. PWM Period and Pulse Width

The value in the TIMB counter modulo registers and the selected prescaler output determines the frequency of the PWM output. The frequency of an 8-bit PWM signal is variable in 256 increments. Writing \$00FF (255) to the TIMB counter modulo registers produces a PWM period of 256 times the internal bus clock period if the prescaler select value is \$000 (see 12.9.1 TIMB Status and Control Register).

The value in the TIMB channel registers determines the pulse width of the PWM output. The pulse width of an 8-bit PWM signal is variable in 256 increments. Writing \$0080 (128) to the TIMB channel registers produces a duty cycle of 128/256 or 50%.

#### 12.4.4.1 Unbuffered PWM Signal Generation

Any output compare channel can generate unbuffered PWM pulses as described in **12.4.4 Pulse Width Modulation (PWM)**. The pulses are unbuffered because changing the pulse width requires writing the new pulse width value over the old value currently in the TIMB channel registers.

An unsynchronized write to the TIMB channel registers to change a pulse width value could cause incorrect operation for up to two PWM periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that PWM period. Also, using a TIMB overflow interrupt

MC68HC708MP16 — Rev. 3.1

routine to write a new, smaller pulse width value can cause the compare to be missed. The TIMB may pass the new value before it is written.

Use the following methods to synchronize unbuffered changes in the PWM pulse width on channel x:

- When changing to a shorter pulse width, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current pulse. The interrupt routine has until the end of the PWM period to write the new value.
- When changing to a longer pulse width, enable channel x TIMB overflow interrupts and write the new value in the TIMB overflow interrupt routine. The TIMB overflow interrupt occurs at the end of the current PWM period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same PWM period.

NOTE:

In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0% duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare also can cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.

### 12.4.4.2 Buffered PWM Signal Generation

Channels 0 and 1 can be linked to form a buffered PWM channel whose output appears on the PTE4/TCH0B pin. The TIMB channel registers of the linked pair alternately control the pulse width of the output.

Setting the MS0B bit in TIMB channel 0 status and control register (TBSC0) links channel 0 and channel 1. The TIMB channel 0 registers initially control the pulse width on the PTE4/TCH0B pin. Writing to the TIMB channel 1 registers enables the TIMB channel 1 registers to synchronously control the pulse width at the beginning of the next PWM period. At each subsequent overflow, the TIMB channel registers (0 or 1) that control the pulse width are the ones written to last. TBSC0 controls and monitors the buffered PWM function, and TIMB channel 1

**Technical Data** 

234

status and control register (TBSC1) is unused. While the MS0B bit is set, the channel 1 pin, PTE5/TCH1B, is available as a general-purpose I/O pin.

Channels 2 and 3 can be linked to form a buffered PWM channel whose output appears on the PTE6/TCH2B pin. The TIMB channel registers of the linked pair alternately control the pulse width of the output.

Setting the MS2B bit in TIMB channel 2 status and control register (TBSC2) links channel 2 and channel 3. The TIMB channel 2 registers initially control the pulse width on the PTE6/TCH2B pin. Writing to the TIMB channel 3 registers enables the TIMB channel 3 registers to synchronously control the pulse width at the beginning of the next PWM period. At each subsequent overflow, the TIMB channel registers (2 or 3) that control the pulse width are the ones written to last. TBSC2 controls and monitors the buffered PWM function, and TIMB channel 3 status and control register (TBSC3) is unused. While the MS2B bit is set, the channel 3 pin, PTE7/TCH3B, is available as a general-purpose I/O pin.

#### **NOTE:**

In buffered PWM signal generation, do not write new pulse width values to the currently active channel registers. Writing to the active channel registers is the same as generating unbuffered PWM signals.

#### 12.4.4.3 PWM Initialization

To ensure correct operation when generating unbuffered or buffered PWM signals, use the following initialization procedure:

- 1. In the TIMB status and control register (TBSC):
  - a. Stop the TIMB counter by setting the TIMB stop bit, TSTOP.
  - b. Reset the TIMB counter by setting the TIMB reset bit, TRST.
- 2. In the TIMB counter modulo registers (TBMODH:TBMODL), write the value for the required PWM period.
- 3. In the TIMB channel x registers (TBCHxH:TBCHxL), write the value for the required pulse width.

MC68HC708MP16 — Rev. 3.1

- 4. In TIMB channel x status and control register (TBSCx):
  - a. Write 0:1 (for unbuffered output compare or PWM signals) or
     1:0 (for buffered output compare or PWM signals) to the mode select bits, MSxB:MSxA. (See Table 12-2.)
  - b. Write 1 to the toggle-on-overflow bit, TOVx.
  - c. Write 1:0 (to clear output on compare) or 1:1 (to set output on compare) to the edge/level select bits, ELSxB:ELSxA. The output action on compare must force the output to the complement of the pulse width level. (See Table 12-2.)

#### NOTE:

In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0% duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare can also cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.

5. In the TIMB status control register (TBSC), clear the TIMB stop bit, TSTOP.

Setting MS0B links channels 0 and 1 and configures them for buffered PWM operation. The TIMB channel 0 registers (TBCH0H:TBCH0L) initially control the buffered PWM output. TIMB status control register 0 (TBSCR0) controls and monitors the PWM signal from the linked channels. MS0B takes priority over MS0A.

Setting MS2B links channels 2 and 3 and configures them for buffered PWM operation. The TIMB channel 2 registers (TBCH2H:TBCH2L) initially control the PWM output. TIMB status control register 2 (TBSCR2) controls and monitors the PWM signal from the linked channels. MS2B takes priority over MS2A.

Clearing the toggle-on-overflow bit, TOVx, inhibits output toggles on TIMB overflows. Subsequent output compares try to force the output to a state it is already in and have no effect. The result is a 0% duty cycle output.

Setting the channel x maximum duty cycle bit (CHxMAX) and clearing the TOVx bit generates a 100% duty cycle output. (See **12.9.4 TIMB Channel Status and Control Registers**.)

## 12.5 Interrupts

The following TIMB sources can generate interrupt requests:

- TIMB overflow flag (TOF) The TOF bit is set when the TIMB counter value rolls over to \$0000 after matching the value in the TIMB counter modulo registers. The TIMB overflow interrupt enable bit, TOIE, enables TIMB overflow CPU interrupt requests. TOF and TOIE are in the TIMB status and control register.
- TIMB channel flags (CH3F–CH0F) The CHxF bit is set when an input capture or output compare occurs on channel x. Channel x TIM CPU interrupt requests are controlled by the channel x interrupt enable bit, CHxIE. Channel x TIM CPU interrupt requests are enabled when CHxIE= 1.
- CHxF and CHxIE are in the TIMB channel x status and control register.

#### 12.6 Wait Mode

The WAIT instruction puts the MCU in low-power-consumption standby mode.

The TIMB remains active after the execution of a WAIT instruction. In wait mode the TIMB registers are not accessible by the CPU. Any enabled CPU interrupt request from the TIMB can bring the MCU out of wait mode.

If TIMB functions are not required during wait mode, reduce power consumption by stopping the TIMB before executing the WAIT instruction.

MC68HC708MP16 — Rev. 3.1

## 12.7 TIMB During Break Interrupts

A break interrupt stops the TIMB counter.

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. (See 7.7.4 SIM Break Flag Control Register.)

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a two-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

## 12.8 I/O Signals

Port E shares five of its pins with the TIM. PTE3/TCLKB is an external clock input to the TIMB prescaler. The four TIMB channel I/O pins are PTE4/TCH0B, PTE5/TCH1B, PTE6/TCH2B, and PTE7/TCH3B.

#### 12.8.1 TIMB Clock Pin (PTE3/TCLKB)

PTE3/TCLKB is an external clock input that can be the clock source for the TIMB counter instead of the prescaled internal bus clock. Select the PTE3/TCLKB input by writing logic 1s to the three prescaler select bits, PS[2:0]. (See 12.9.1 TIMB Status and Control Register.)

The minimum TCLK pulse width, TCLK<sub>LMIN</sub> or TCLK<sub>HMIN</sub>, is:

$$\frac{1}{\text{bus frequency}} + t_{SU}$$

The maximum TCLK frequency is:

bus frequency ÷ 2

PTE3/TCLKB is available as a general-purpose I/O pin when not used as the TIMB clock input. When the PTE3/TCLKB pin is the TIMB clock input, it is an input regardless of the state of the DDRE3 bit in data direction register E.

#### 12.8.2 TIMB Channel I/O Pins (PTE4/TCH0B:PTE7/TCH3B)

Each channel I/O pin is programmable independently as an input capture pin or an output compare pin. PTE4/TCH0B and PTE6/TCH2B can be configured as buffered output compare or buffered PWM pins.

## 12.9 I/O Registers

The following I/O registers control and monitor operation of the TIMB:

- TIMB status and control register (TBSC)
- TIMB control registers (TBCNTH:TBCNTL)
- TIMB counter modulo registers (TBMODH:TBMODL)
- TIMB channel status and control registers (TBSC0, TBSC1, TBSC2, and TBSC3)
- TIMB channel registers (TBCH0H:TBCH0L, TBCH1H:TBCH1L, TBCH2H:TBCH2L, and TBCH3H:TBCH3L)

#### 12.9.1 TIMB Status and Control Register

The TIMB status and control register does the following:

- Enables TIMB overflow interrupts
- Flags TIMB overflows
- Stops the TIMB counter
- Resets the TIMB counter
- Prescales the TIMB counter clock

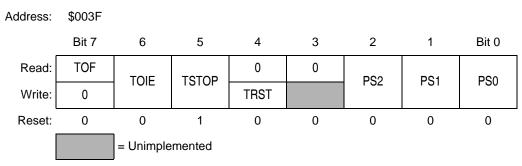

Figure 12-4. TIMB Status and Control Register (TBSC)

#### TOF — TIMB Overflow Flag Bit

This read/write flag is set when the TIMB counter resets to \$0000 after reaching the modulo value programmed in the TIMB counter modulo registers. Clear TOF by reading the TIMB status and control register when TOF is set and then writing a logic 0 to TOF. If another TIMB overflow occurs before the clearing sequence is complete, then writing logic 0 to TOF has no effect. Therefore, a TOF interrupt request cannot be lost due to inadvertent clearing of TOF. Reset clears the TOF bit. Writing a logic 1 to TOF has no effect.

- 1 = TIMB counter has reached modulo value
- 0 = TIMB counter has not reached modulo value

#### TOIE — TIMB Overflow Interrupt Enable Bit

This read/write bit enables TIMB overflow interrupts when the TOF bit becomes set. Reset clears the TOIE bit.

- 1 = TIMB overflow interrupts enabled
- 0 = TIMB overflow interrupts disabled

#### TSTOP — TIMB Stop Bit

This read/write bit stops the TIMB counter. Counting resumes when TSTOP is cleared. Reset sets the TSTOP bit, stopping the TIMB counter until software clears the TSTOP bit.

1 = TIMB counter stopped

0 = TIMB counter active

**NOTE:** Do not set the TSTOP bit before entering wait mode if the TIMB is required to exit wait mode.

#### TRST — TIMB Reset Bit

Setting this write-only bit resets the TIMB counter and the TIMB prescaler. Setting TRST has no effect on any other registers. Counting resumes from \$0000. TRST is cleared automatically after the TIMB counter is reset and always reads as logic 0. Reset clears the TRST bit.

1 = Prescaler and TIMB counter cleared

0 = No effect

**NOTE:** Setting the TSTOP and TRST bits simultaneously stops the TIMB counter at a value of \$0000.

#### PS[2:0] — Prescaler Select Bits

These read/write bits select either the PTE3/TCLKB pin or one of the seven prescaler outputs as the input to the TIMB counter as **Table 12-1** shows. Reset clears the PS[2:0] bits.

**Table 12-1. Prescaler Selection** 

PS[2:0]	TIMB Clock Source
000	Internal Bus Clock ÷1
001	Internal Bus Clock ÷ 2
010	Internal Bus Clock ÷ 4
011	Internal Bus Clock ÷ 8
100	Internal Bus Clock ÷ 16
101	Internal Bus Clock ÷ 32
110	Internal Bus Clock ÷ 64
111	PTE3/TCLKB

MC68HC708MP16 - Rev. 3.1

#### 12.9.2 TIMB Counter Registers

The two read-only TIMB counter registers contain the high and low bytes of the value in the TIMB counter. Reading the high byte (TBCNTH) latches the contents of the low byte (TBCNTL) into a buffer. Subsequent reads of TBCNTH do not affect the latched TBCNTL value until TBCNTL is read. Reset clears the TIMB counter registers. Setting the TIMB reset bit (TRST) also clears the TIMB counter registers.

**NOTE:** 

If you read TBCNTH during a break interrupt, be sure to unlatch TBCNTL by reading TBCNTL before exiting the break interrupt. Otherwise, TBCNTL retains the value latched during the break.

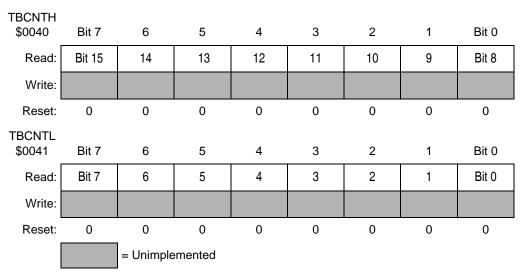

Figure 12-5. TIMB Counter Registers (TBCNTH:TBCNTL)

#### 12.9.3 TIMB Counter Modulo Registers

The read/write TIMB modulo registers contain the modulo value for the TIMB counter. When the TIMB counter reaches the modulo value, the overflow flag (TOF) becomes set, and the TIMB counter resumes counting from \$0000 at the next clock. Writing to the high byte (TBMODH) inhibits the TOF bit and overflow interrupts until the low byte (TBMODL) is written. Reset sets the TIMB counter modulo registers.

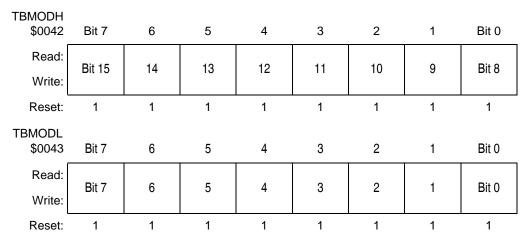

Figure 12-6. TIMB Counter Modulo Registers (TBMODH:TBMODL)

**NOTE:** Reset the TIMB counter before writing to the TIMB counter modulo registers.

## 12.9.4 TIMB Channel Status and Control Registers

Each of the TIMB channel status and control registers does the following:

- Flags input captures and output compares
- Enables input capture and output compare interrupts
- Selects input capture, output compare, or PWM operation
- Selects high, low, or toggling output on output compare
- Selects rising edge, falling edge, or any edge as the active input capture trigger
- Selects output toggling on TIMB overflow
- Selects 100% PWM duty cycle
- Selects buffered or unbuffered output compare/PWM operation

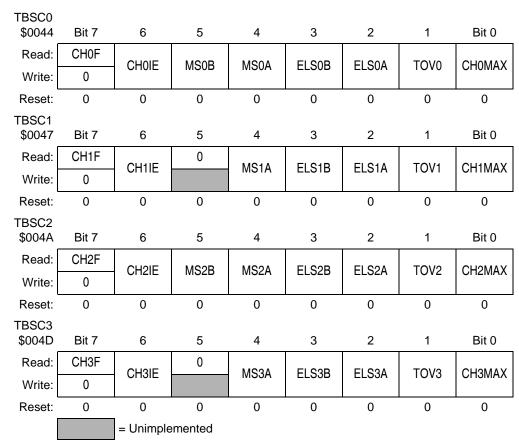

Figure 12-7. TIMB Channel Status and Control Registers (TBSC0:TBSC3)

#### CHxF — Channel x Flag Bit

When channel x is an input capture channel, this read/write bit is set when an active edge occurs on the channel x pin. When channel x is an output compare channel, CHxF is set when the value in the TIMB counter registers matches the value in the TIMB channel x registers.

When TIM CPU interrupt requests are enabled (CHxIE = 1), clear CHxF by reading TIMB channel x status and control register with CHxF set and then writing a logic 0 to CHxF. If another interrupt request occurs before the clearing sequence is complete, then writing logic 0 to CHxF has no effect. Therefore, an interrupt request cannot be lost due to inadvertent clearing of CHxF.

Reset clears the CHxF bit. Writing a logic 1 to CHxF has no effect.

- 1 = Input capture or output compare on channel x
- 0 = No input capture or output compare on channel x

#### CHxIE — Channel x Interrupt Enable Bit

This read/write bit enables TIMB CPU interrupts on channel x.

Reset clears the CHxIE bit.

- 1 = Channel x CPU interrupt requests enabled
- 0 = Channel x CPU interrupt requests disabled

#### MSxB — Mode Select Bit B

This read/write bit selects buffered output compare/PWM operation. MSxB exists only in the TIMB channel 0 and TIMB channel 2 status and control registers.

Setting MS0B disables the channel 1 status and control register and reverts TCH1B to general-purpose I/O.

Setting MS2B disables the channel 3 status and control register and reverts TCH3B to general-purpose I/O.

Reset clears the MSxB bit.

- 1 = Buffered output compare/PWM operation enabled
- 0 = Buffered output compare/PWM operation disabled

MSxA — Mode Select Bit A

When ELSxB:A  $\neq$  00, this read/write bit selects either input capture operation or unbuffered output compare/PWM operation. (See **Table 12-2**.)

- 1 = Unbuffered output compare/PWM operation
- 0 = Input capture operation

When ELSxB:A = 00, this read/write bit selects the initial output level of the TCHxB pin. (See **Table 12-2**.) Reset clears the MSxA bit.

- 1 = Initial output level low
- 0 = Initial output level high

**NOTE:** Before changing a channel function by writing to the MSxB or MSxA bit, set the TSTOP and TRST bits in the TIMB status and control register (TBSC).

ELSxB and ELSxA — Edge/Level Select Bits

When channel x is an input capture channel, these read/write bits control the active edge-sensing logic on channel x.

When channel x is an output compare channel, ELSxB and ELSxA control the channel x output behavior when an output compare occurs.

When ELSxB and ELSxA are both clear, channel x is not connected to port E, and pin PTEx/TCHxB is available as a general-purpose I/O pin. **Table 12-2** shows how ELSxB and ELSxA work. Reset clears the ELSxB and ELSxA bits.

**NOTE:** Before enabling a TIMB channel register for input capture operation, make sure that the PTE/TCHxB pin is stable for at least two bus clocks.

#### TOVx — Toggle-On-Overflow Bit

10

11

01

10

11

01

01 1X

1X

1X

When channel x is an output compare channel, this read/write bit controls the behavior of the channel x output when the TIMB counter overflows. When channel x is an input capture channel, TOVx has no effect. Reset clears the TOVx bit.

- 1 = Channel x pin toggles on TIMB counter overflow.
- 0 = Channel x pin does not toggle on TIMB counter overflow.

# **NOTE:** When TOVx is set, a TIMB counter overflow takes precedence over a channel x output compare if both occur at the same time.

#### CHxMAX — Channel x Maximum Duty Cycle Bit

When the TOVx bit is at logic 0, setting the CHxMAX bit forces the duty cycle of buffered and unbuffered PWM signals to 100%. As **Figure 12-8** shows, the CHxMAX bit takes effect in the cycle after it is set or cleared. The output stays at the 100% duty cycle level until the cycle after CHxMAX is cleared.

MC68HC708MP16 — Rev. 3.1

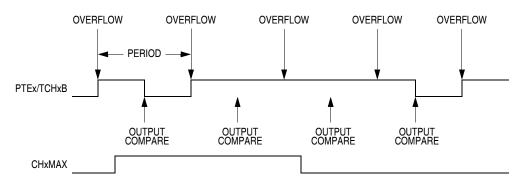

Figure 12-8. CHxMAX Latency

#### 12.9.5 TIMB Channel Registers

These read/write registers contain the captured TIMB counter value of the input capture function or the output compare value of the output compare function. The state of the TIMB channel registers after reset is unknown.

In input capture mode (MSxB:MSxA = 0:0), reading the high byte of the TIMB channel x registers (TBCHxH) inhibits input captures until the low byte (TBCHxL) is read.

In output compare mode (MSxB:MSxA  $\neq$  0:0), writing to the high byte of the TIMB channel x registers (TBCHxH) inhibits output compares until the low byte (TBCHxL) is written.

## Serial Peripheral Interface Module (SPI)

13.14 I/C	Registers	276
13.14.1	SPI Control Register	277
13.14.2	SPI Status and Control Register	279
13.14.3	SPI Data Register	282

#### 13.2 Introduction

The SPI allows full-duplex, synchronous, serial communications with peripheral devices.

#### 13.3 Features

Features of the SPI module include the following:

- Full-duplex operation
- Master and slave modes
- Double-buffered operation with separate transmit and receive registers
- Four master mode frequencies (maximum = bus frequency ÷ 2)
- Maximum slave mode frequency = bus frequency
- Clock ground for reduced radio frequency (RF) interference
- Serial clock with programmable polarity and phase
- Two separately enabled interrupts with CPU service:
  - SPRF (SPI receiver full)
  - SPTE (SPI transmitter empty)
- Mode fault error flag with cpu interrupt capability
- Overflow error flag with CPU interrupt capability
- Programmable wired-OR mode
- I<sup>2</sup>C (inter-integrated circuit) compatibility

## 13.4 Pin Name Conventions

The generic names of the SPI I/O pins are:

- SS (slave select)
- SPSCK (SPI serial clock)
- CGND (clock ground)
- MOSI (master out slave in)
- MISO (master in slave out)

SPI pins are shared by parallel I/O ports or have alternate functions. The full name of an SPI pin reflects the name of the shared port pin or the name of an alternate pin function. The generic pin names appear in the text that follows. **Table 13-1** shows the full names of the SPI I/O pins.

**Table 13-1. Pin Name Conventions** 

Generic Pin Names:	MISO	MOSI	SPSCK	SS	CGND
Full Pin Names:	PF3/MISO	PF2/MOSI	PF0/SPSCK	PF1/SS	CGND/EV <sub>SS</sub>

# 13.5 Functional Description

**Figure 13-1** shows the structure of the SPI module and **Figure 13-2** shows the locations and contents of the SPI I/O registers.

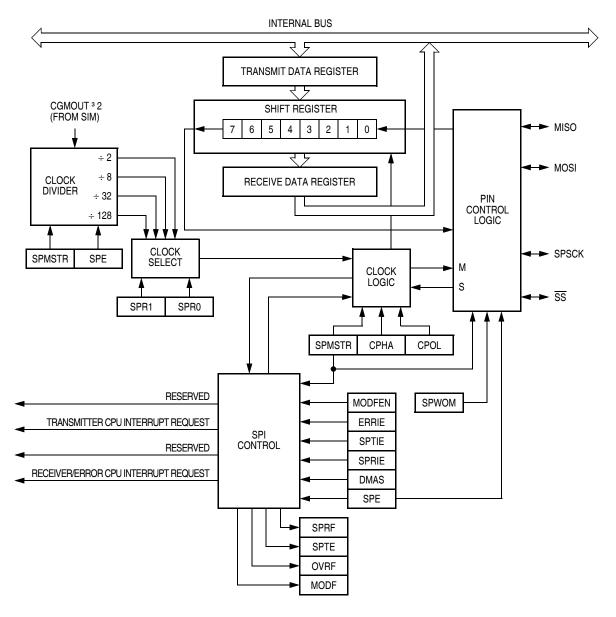

Figure 13-1. SPI Module Block Diagram

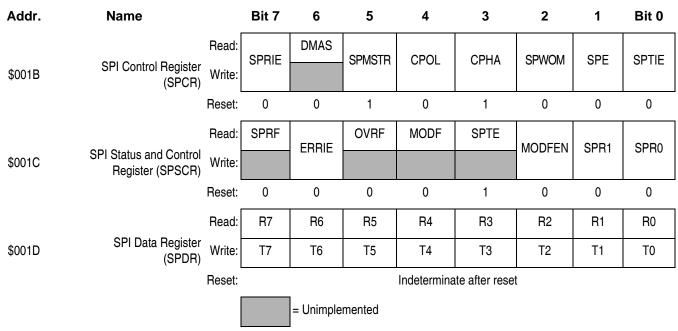

Figure 13-2. SPI I/O Register Summary

The SPI module allows full-duplex, synchronous, serial communication between the MCU and peripheral devices, including other MCUs. Software can poll the SPI status flags or SPI operation can be interrupt-driven. All SPI interrupts can be serviced by the CPU.

The following paragraphs describe the operation of the SPI module.

#### 13.5.1 Master Mode

The SPI operates in master mode when the SPI master bit, SPMSTR, is set.

#### NOTE:

Configure the SPI modules as master or slave before enabling them. Enable the master SPI before enabling the slave SPI. Disable the slave SPI before disabling the master SPI. (See 13.14.1 SPI Control Register.)

MC68HC708MP16 — Rev. 3.1

Only a master SPI module can initiate transmissions. Software begins the transmission from a master SPI module by writing to the transmit data register. If the shift register is empty, the byte immediately transfers to the shift register, setting the SPI transmitter empty bit, SPTE. The byte begins shifting out on the MOSI pin under the control of the serial clock. See **Figure 13-3**.

The SPR1 and SPR0 bits control the baud rate generator and determine the speed of the shift register. (See 13.14.2 SPI Status and Control Register.) Through the SPSCK pin, the baud rate generator of the master also controls the shift register of the slave peripheral.

As the byte shifts out on the MOSI pin of the master, another byte shifts in from the slave on the master's MISO pin. The transmission ends when the receiver full bit, SPRF, becomes set. At the same time that SPRF becomes set, the byte from the slave transfers to the receive data register. In normal operation, SPRF signals the end of a transmission. Software clears SPRF by reading the SPI status and control register with SPRF set and then reading the SPI data register. Writing to the SPI data register clears the SPTE bit.

When the DMAS bit is set, the SPI status and control register does not have to be read to clear the SPRF bit. A read of the SPI data register by the CPU clears the SPRF bit. A write to the SPI data register by the CPU clears the SPTE bit.

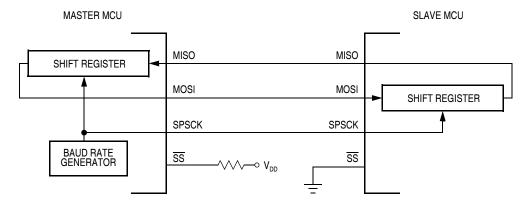

Figure 13-3. Full-Duplex Master-Slave Connections

#### 13.5.2 Slave Mode

The SPI operates in slave mode when the SPMSTR bit is clear. In slave mode the SPSCK pin is the input for the serial clock from the master MCU. Before a data transmission occurs, the SS pin of the slave SPI must be at logic 0. SS must remain low until the transmission is complete. (See 13.8.2 Mode Fault Error.)

In a slave SPI module, data enters the shift register under the control of the serial clock from the master SPI module. After a byte enters the shift register of a slave SPI, it transfers to the receive data register, and the SPRF bit is set. To prevent an overflow condition, slave software then must read the receive data register before another full byte enters the shift register.

The maximum frequency of the SPSCK for an SPI configured as a slave is the bus clock speed (which is twice as fast as the fastest master SPSCK clock that can be generated). The frequency of the SPSCK for an SPI configured as a slave does not have to correspond to any SPI baud rate. The baud rate only controls the speed of the SPSCK generated by an SPI configured as a master. Therefore, the frequency of the SPSCK for an SPI configured as a slave can be any frequency less than or equal to the bus speed.

When the master SPI starts a transmission, the data in the slave shift register begins shifting out on the MISO pin. The slave can load its shift register with a new byte for the next transmission by writing to its transmit data register. The slave must write to its transmit data register at least one bus cycle before the master starts the next transmission. Otherwise the byte already in the slave shift register shifts out on the MISO pin. Data written to the slave shift register during a transmission remains in a buffer until the end of the transmission.

When the clock phase bit (CPHA) is set, the first edge of SPSCK starts a transmission. When CPHA is clear, the falling edge of  $\overline{SS}$  starts a transmission. (See 13.6 Transmission Formats.)

**NOTE:** SPSCK must be in the proper idle state before the slave is enabled to prevent SPSCK from appearing as a clock edge.

MC68HC708MP16 - Rev. 3.1

## 13.6 Transmission Formats

During an SPI transmission, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). A serial clock synchronizes shifting and sampling on the two serial data lines. A slave select line allows selection of an individual slave SPI device; slave devices that are not selected do not interfere with SPI bus activities. On a master SPI device, the slave select line can optionally be used to indicate multiple-master bus contention.

## 13.6.1 Clock Phase and Polarity Controls

Software can select any of four combinations of serial clock (SPSCK) phase and polarity using two bits in the SPI control register (SPCR). The clock polarity is specified by the CPOL control bit, which selects an active high or low clock and has no significant effect on the transmission format.

The clock phase (CPHA) control bit selects one of two fundamentally different transmission formats. The clock phase and polarity should be identical for the master SPI device and the communicating slave device. In some cases, the phase and polarity are changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

**NOTE:** Before writing to the CPOL bit or the CPHA bit, disable the SPI by clearing the SPI enable bit (SPE).

## 13.6.2 Transmission Format When CPHA = 0

Figure 13-4 shows an SPI transmission in which CPHA is logic 0. The figure should not be used as a replacement for data sheet parametric information. Two waveforms are shown for SPSCK: one for CPOL = 0 and another for CPOL = 1. The diagram may be interpreted as a master or slave timing diagram since the serial clock (SPSCK), master in/slave out (MISO), and master out/slave in (MOSI) pins are directly connected between the master and the slave. The MISO signal is the output from the slave, and the MOSI signal is the output from the master. The  $\overline{\rm SS}$  line

is the slave select input to the slave. The slave SPI drives its MISO output only when its slave select input  $(\overline{SS})$  is at logic 0, so that only the selected slave drives to the master. The  $\overline{SS}$  pin of the master is not shown but is assumed to be inactive. The  $\overline{SS}$  pin of the master must be high or must be reconfigured as general-purpose I/O not affecting the SPI. (See 13.8.2 Mode Fault Error.) When CPHA = 0, the first SPSCK edge is the MSB capture strobe. Therefore the slave must begin driving its data before the first SPSCK edge, and a falling edge on the  $\overline{SS}$  pin is used to start the slave data transmission. The slave's  $\overline{SS}$  pin must be toggled back to high and then low again between each byte transmitted as shown in Figure 13-5.

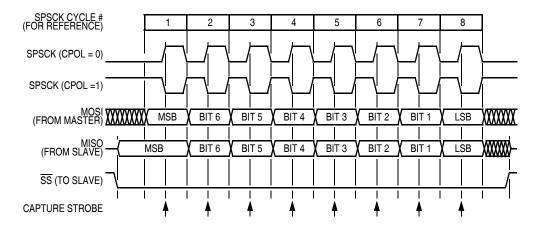

Figure 13-4. Transmission Format (CPHA = 0)

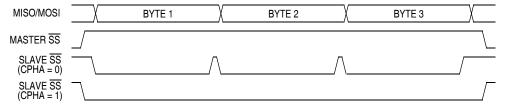

Figure 13-5. CPHA/SS Timing

When CPHA = 0 for a slave, the falling edge of  $\overline{SS}$  indicates the beginning of the transmission. This causes the SPI to leave its idle state and begin driving the MISO pin with the MSB of its data. Once the transmission begins, no new data is allowed into the shift register from the transmit data register. Therefore, the SPI data register of the slave

MC68HC708MP16 — Rev. 3.1

must be loaded with transmit data before the falling edge of  $\overline{SS}$ . Any data written after the falling edge is stored in the transmit data register and transferred to the shift register after the current transmission.

#### 13.6.3 Transmission Format When CPHA = 1

Figure 13-6 shows an SPI transmission in which CPHA is logic 1. The figure should not be used as a replacement for data sheet parametric information. Two waveforms are shown for SPSCK: one for CPOL = 0 and another for CPOL = 1. The diagram may be interpreted as a master or slave timing diagram since the serial clock (SPSCK), master in/slave out (MISO), and master out/slave in (MOSI) pins are directly connected between the master and the slave. The MISO signal is the output from the slave, and the MOSI signal is the output from the master. The SS line is the slave select input to the slave. The slave SPI drives its MISO output only when its slave select input  $(\overline{SS})$  is at logic 0, so that only the selected slave drives to the master. The  $\overline{SS}$  pin of the master is not shown but is assumed to be inactive. The SS pin of the master must be high or must be reconfigured as general-purpose I/O not affecting the SPI. (See 13.8.2 Mode Fault Error.) When CPHA = 1, the master begins driving its MOSI pin on the first SPSCK edge. Therefore the slave uses the first SPSCK edge as a start transmission signal. The SS pin can remain low between transmissions. This format may be preferable in systems having only one master and only one slave driving the MISO data line.

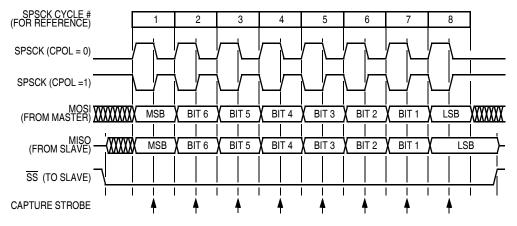

Figure 13-6. Transmission Format (CPHA = 1)

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

When CPHA = 1 for a slave, the first edge of the SPSCK indicates the beginning of the transmission. This causes the SPI to leave its idle state and begin driving the MISO pin with the MSB of its data. Once the transmission begins, no new data is allowed into the shift register from the transmit data register. Therefore, the SPI data register of the slave must be loaded with transmit data before the first edge of SPSCK. Any data written after the first edge is stored in the transmit data register and transferred to the shift register after the current transmission.

## 13.6.4 Transmission Initiation Latency

When the SPI is configured as a master (SPMSTR = 1), writing to the SPDR starts a transmission. CPHA has no effect on the delay to the start of the transmission, but it does affect the initial state of the SPSCK signal. When CPHA = 0, the SPSCK signal remains inactive for the first half of the first SPSCK cycle. When CPHA = 1, the first SPSCK cycle begins with an edge on the SPSCK line from its inactive to its active level. The SPI clock rate (selected by SPR1:SPR0) affects the delay from the write to SPDR and the start of the SPI transmission. (See Figure 13-7.) The internal SPI clock in the master is a free-running derivative of the internal MCU clock. To conserve power, it is enabled only when both the SPE and SPMSTR bits are set. SPSCK edges occur halfway through the low time of the internal MCU clock. Since the SPI clock is free-running, it is uncertain where the write to the SPDR occurs relative to the slower SPSCK. This uncertainty causes the variation in the initiation delay shown in Figure 13-7. This delay is no longer than a single SPI bit time. That is, the maximum delay is two MCU bus cycles for DIV2, eight MCU bus cycles for DIV8, 32 MCU bus cycles for DIV32, and 128 MCU bus cycles for DIV128.

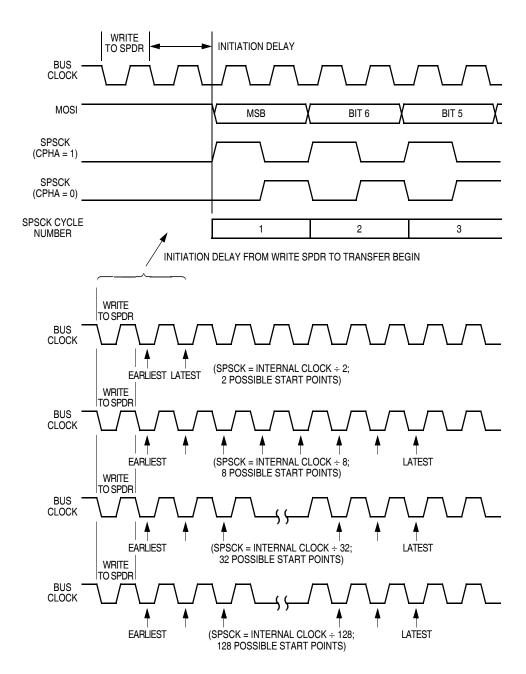

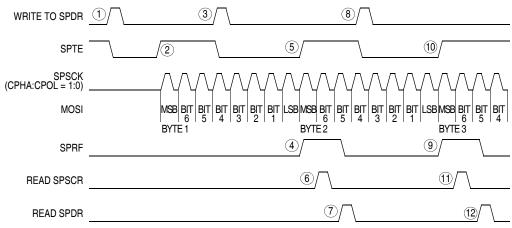

Figure 13-7. Transmission Start Delay (Master)

# 13.7 Queuing Transmission Data

The double-buffered transmit data register allows a data byte to be queued and transmitted. For an SPI configured as a master, a queued data byte is transmitted immediately after the previous transmission has completed. The SPI transmitter empty flag (SPTE) indicates when the transmit data buffer is ready to accept new data. Write to the transmit data register only when the SPTE bit is high. **Figure 13-8** shows the timing associated with doing back-to-back transmissions with the SPI (SPSCK has CPHA: CPOL = 1:0).

- (1) CPU WRITES BYTE 1 TO SPDR, CLEARING SPTE BIT.
- (2) BYTE 1 TRANSFERS FROM TRANSMIT DATA REGISTER TO SHIFT REGISTER, SETTING SPTE BIT.
- ③ CPU WRITES BYTE 2 TO SPDR, QUEUEING BYTE 2 AND CLEARING SPTE BIT.
- FIRST INCOMING BYTE TRANSFERS FROM SHIFT REGISTER TO RECEIVE DATA REGISTER, SETTING SPRF BIT.
- (5) BYTE 2 TRANSFERS FROM TRANSMIT DATA REGISTER TO SHIFT REGISTER, SETTING SPTE BIT.
- (6) CPU READS SPSCR WITH SPRF BIT SET.

- (7) CPU READS SPDR, CLEARING SPRF BIT.
- 8 CPU WRITES BYTE 3 TO SPDR, QUEUEING BYTE 3 AND CLEARING SPTE BIT.
- 9 SECOND INCOMING BYTE TRANSFERS FROM SHIFT REGISTER TO RECEIVE DATA REGISTER, SETTING SPRF BIT.
- BYTE 3 TRANSFERS FROM TRANSMIT DATA REGISTER TO SHIFT REGISTER, SETTING SPTE BIT.
- (1) CPU READS SPSCR WITH SPRF BIT SET.
- (12) CPU READS SPDR, CLEARING SPRF BIT.

Figure 13-8. SPRF/SPTE CPU Interrupt Timing

The transmit data buffer allows back-to-back transmissions without the slave precisely timing its writes between transmissions as in a system with a single data buffer. Also, if no new data is written to the data buffer, the last value contained in the shift register is the next data word to be transmitted.

MC68HC708MP16 - Rev. 3.1

For an idle master or idle slave that has no data loaded into its transmit buffer, the SPTE is set again no more than two bus cycles after the transmit buffer empties into the shift register. This allows the user to queue up a 16-bit value to send. For an already active slave, the load of the shift register cannot occur until the transmission is completed. This implies that a back-to-back write to the transmit data register is not possible. The SPTE indicates when the next write can occur.

## 13.8 Error Conditions

The following flags signal SPI error conditions:

- Overflow (OVRF) Failing to read the SPI data register before the next full byte enters the shift register sets the OVRF bit. The new byte does not transfer to the receive data register, and the unread byte still can be read. OVRF is in the SPI status and control register.
- Mode fault error (MODF) The MODF bit indicates that the voltage on the slave select pin (SS) is inconsistent with the mode of the SPI. MODF is in the SPI status and control register.

#### 13.8.1 Overflow Error

The overflow flag (OVRF) becomes set if the receive data register still has unread data from a previous transmission when the capture strobe of bit 1 of the next transmission occurs. The bit 1 capture strobe occurs in the middle of SPSCK cycle 7. (See Figure 13-4 and Figure 13-6.) If an overflow occurs, all data received after the overflow and before the OVRF bit is cleared does not transfer to the receive data register and does not set the SPI receiver full bit (SPRF). The unread data that transferred to the receive data register before the overflow occurred can still be read. Therefore, an overflow error always indicates the loss of data. Clear the overflow flag by reading the SPI status and control register and then reading the SPI data register.

OVRF generates a receiver/error CPU interrupt request if the error interrupt enable bit (ERRIE) is also set. When the DMAS bit is low, the SPRF, MODF, and OVRF interrupts share the same CPU interrupt vector. (See **Figure 13-11**.) It is not possible to enable MODF or OVRF individually to generate a receiver/error CPU interrupt request. However, leaving MODFEN low prevents MODF from being set.

If the CPU SPRF interrupt is enabled and the OVRF interrupt is not, watch for an overflow condition. **Figure 13-9** shows how it is possible to miss an overflow. The first part of **Figure 13-9** shows how it is possible to read the SPSCR and SPDR to clear the SPRF without problems. However, as illustrated by the second transmission example, the OVRF bit can be set in between the time that SPSCR and SPDR are read.

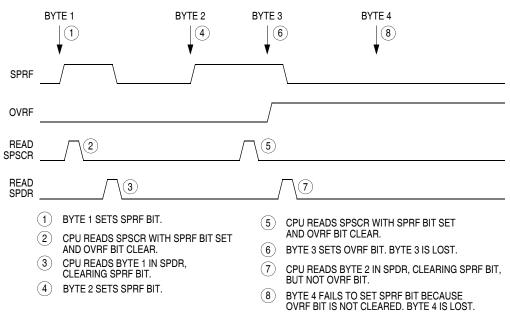

Figure 13-9. Missed Read of Overflow Condition

In this case, an overflow can easily be missed. Since no more SPRF interrupts can be generated until this OVRF is serviced, it is not obvious that bytes are being lost as more transmissions are completed. To prevent this, either enable the OVRF interrupt or do another read of the SPSCR following the read of the SPDR. This ensures that the OVRF was not set before the SPRF was cleared and that future transmissions can set the SPRF bit. Figure 13-10 illustrates this process. Generally, to avoid this second SPSCR read, enable the OVRF to the CPU by setting the ERRIE bit.

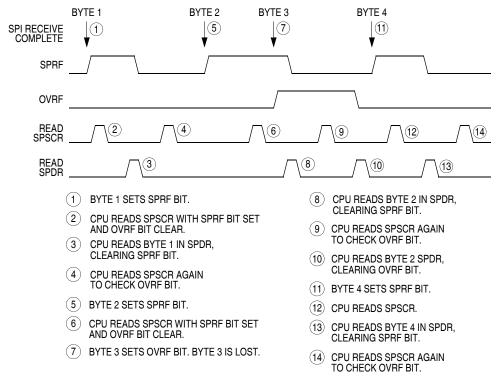

Figure 13-10. Clearing SPRF When OVRF Interrupt Is Not Enabled

#### 13.8.2 Mode Fault Error

Setting the SPMSTR bit selects master mode and configures the SPSCK and MOSI pins as outputs and the MISO pin as an input. Clearing SPMSTR selects slave mode and configures the SPSCK and MOSI pins as inputs and the MISO pin as an output. The mode fault bit, MODF, becomes set any time the state of the slave select pin,  $\overline{SS}$ , is inconsistent with the mode selected by SPMSTR. To prevent SPI pin contention and damage to the MCU, a mode fault error occurs if:

- The SS pin of a slave SPI goes high during a transmission
- The SS pin of a master SPI goes low at any time.

For the MODF flag to be set, the mode fault error enable bit (MODFEN) must be set. Clearing the MODFEN bit does not clear the MODF flag but does prevent MODF from being set again after MODF is cleared.

MODF generates a receiver/error CPU interrupt request if the error interrupt enable bit (ERRIE) is also set. When the DMAS bit is low, the SPRF, MODF, and OVRF interrupts share the same CPU interrupt vector. (See **Figure 13-11**.) It is not possible to enable MODF or OVRF individually to generate a receiver/error CPU interrupt request. However, leaving MODFEN low prevents MODF from being set.

In a master SPI with the mode fault enable bit (MODFEN) set, the mode fault flag (MODF) is set if SS goes to logic 0. A mode fault in a master SPI causes the following events to occur:

- If ERRIE = 1, the SPI generates an SPI receiver/error CPU interrupt request.
- The SPE bit is cleared.
- The SPTE bit is set.
- The SPI state counter is cleared.
- The data direction register of the shared I/O port regains control of port drivers.

**NOTE:** To prevent bus contention with another master SPI after a mode fault error, clear all SPI bits of the data direction register of the shared I/O port before enabling the SPI.

MC68HC708MP16 — Rev. 3.1

When configured as a slave (SPMSTR = 0), the MODF flag is set if  $\overline{SS}$  goes high during a transmission. When CPHA = 0, a transmission begins when  $\overline{SS}$  goes low and ends once the incoming SPSCK goes back to its idle level following the shift of the eighth data bit. When CPHA = 1, the transmission begins when the SPSCK leaves its idle level and  $\overline{SS}$  is already low. The transmission continues until the SPSCK returns to its idle level following the shift of the last data bit. (See **13.6 Transmission Formats**.)

**NOTE:** 

Setting the MODF flag does not clear the SPMSTR bit. The SPMSTR bit has no function when SPE = 0. Reading SPMSTR when MODF = 1 shows the difference between a MODF occurring when the SPI is a master and when it is a slave.

When CPHA = 0, a MODF occurs if a slave is selected ( $\overline{SS}$  is at logic 0) and later unselected ( $\overline{SS}$  is at logic 1) even if no SPSCK is sent to that slave. This happens because  $\overline{SS}$  at logic 0 indicates the start of the transmission (MISO driven out with the value of MSB) for CPHA = 0. When CPHA = 1, a slave can be selected and then later unselected with no transmission occurring. Therefore, MODF does not occur since a transmission was never begun.

In a slave SPI (MSTR = 0), the MODF bit generates an SPI receiver/error CPU interrupt request if the ERRIE bit is set. The MODF bit does not clear the SPE bit or reset the SPI in any way. Software can abort the SPI transmission by clearing the SPE bit of the slave.

**NOTE:** 

A logic 1 voltage on the SS pin of a slave SPI puts the MISO pin in a high impedance state. Also, the slave SPI ignores all incoming SPSCK clocks, even if it was already in the middle of a transmission.

To clear the MODF flag, read the SPSCR with the MODF bit set and then write to the SPCR register. This entire clearing mechanism must occur with no MODF condition existing or else the flag is not cleared.

# 13.9 Interrupts

Four SPI status flags can be enabled to generate CPU interrupt requests:

Table 13-2. SPI Interrupts

Flag	Request
SPTE (Transmitter Empty)	SPI Transmitter CPU Interrupt Request (DMAS = 0, SPTIE = 1,SPE = 1)
SPRF (ReceiverFull)	SPI Receiver CPU Interrupt Request (DMAS = 0, SPRIE = 1)
OVRF (Overflow)	SPI Receiver/Error Interrupt Request (ERRIE = 1)
MODF (Mode Fault)	SPI Receiver/Error Interrupt Request (ERRIE = 1)

Reading the SPI status and control register with SPRF set and then reading the receive data register clears SPRF. The clearing mechanism for the SPTE flag is always just a write to the transmit data register.

The SPI transmitter interrupt enable bit (SPTIE) enables the SPTE flag to generate transmitter CPU interrupt requests, provided that the SPI is enabled (SPE = 1).

The SPI receiver interrupt enable bit (SPRIE) enables the SPRF bit to generate receiver CPU interrupt requests, regardless of the state of the SPE bit. (See Figure 13-11.)

The error interrupt enable bit (ERRIE) enables both the MODF and OVRF bits to generate a receiver/error CPU interrupt request.

The mode fault enable bit (MODFEN) can prevent the MODF flag from being set so that only the OVRF bit is enabled by the ERRIE bit to generate receiver/error CPU interrupt requests.

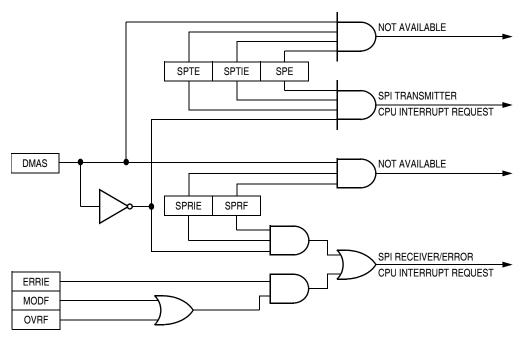

Figure 13-11. SPI Interrupt Request Generation

The following sources in the SPI status and control register can generate CPU interrupt requests:

- SPI receiver full bit (SPRF) The SPRF bit becomes set every time a byte transfers from the shift register to the receive data register. If the SPI receiver interrupt enable bit, SPRIE, is also set, SPRF generates an SPI receiver/error CPU interrupt request.
- SPI transmitter empty (SPTE) The SPTE bit becomes set every time a byte transfers from the transmit data register to the shift register. If the SPI transmit interrupt enable bit, SPTIE, is also set, SPTE generates an SPTE CPU interrupt request.

# 13.10 Resetting the SPI

Any system reset completely resets the SPI. Partial resets occur whenever the SPI enable bit (SPE) is low. Whenever SPE is low, the following occurs:

- The SPTE flag is set
- Any transmission currently in progress is aborted
- The shift register is cleared
- The SPI state counter is cleared, making it ready for a new complete transmission
- All the SPI port logic is defaulted back to being general purpose I/O.

The following items are reset only by a system reset:

- All control bits in the SPCR register
- All control bits in the SPSCR register (MODFEN, ERRIE, SPR1, and SPR0)
- The status flags SPRF, OVRF, and MODF

By not resetting the control bits when SPE is low, the user can clear SPE between transmissions without having to set all control bits again when SPE is set back high for the next transmission.

By not resetting the SPRF, OVRF, and MODF flags, the user can still service these interrupts after the SPI has been disabled. The user can disable the SPI by writing 0 to the SPE bit. The SPI can also be disabled by a mode fault occurring in an SPI that was configured as a master with the MODFEN bit set.

## 13.11 Low-Power Mode

The WAIT instruction puts the MCU in a low-power-consumption standby mode.

The SPI module remains active after the execution of a WAIT instruction. In wait mode the SPI module registers are not accessible by the CPU. Any enabled CPU interrupt request from the SPI module can bring the MCU out of wait mode.

If SPI module functions are not required during wait mode, reduce power consumption by disabling the SPI module before executing the WAIT instruction.

## 13.12 SPI During Break Interrupts

The system integration module (SIM) controls whether status bits in other modules can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state. (See Section 7. System Integration Module (SIM).)

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a two-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

Since the SPTE bit cannot be cleared during a break with the BCFE bit cleared, a write to the transmit data register in break mode does not initiate a transmission, nor is this data transferred into the shift register. Therefore, a write to the SPDR in break mode with the BCFE bit cleared has no effect.

# 13.13 I/O Signals

The SPI module has five I/O pins and shares four of them with a parallel I/O port.

- MISO Data received
- MOSI Data transmitted
- SPSCK Serial clock
- SS Slave select
- CGND Clock ground

The SPI has limited inter-integrated circuit ( $I^2C$ ) capability (requiring software support) as a master in a single-master environment. To communicate with  $I^2C$  peripherals, MOSI becomes an open-drain output when the SPWOM bit in the SPI control register is set. In  $I^2C$  communication, the MOSI and MISO pins are connected to a bidirectional pin from the  $I^2C$  peripheral and through a pullup resistor to  $V_{DD}$ .

## 13.13.1 MISO (Master In/Slave Out)

MISO is one of the two SPI module pins that transmits serial data. In full duplex operation, the MISO pin of the master SPI module is connected to the MISO pin of the slave SPI module. The master SPI simultaneously receives data on its MISO pin and transmits data from its MOSI pin.

Slave output data on the MISO pin is enabled only when the SPI is configured as a slave. The SPI is configured as a slave when its SPMSTR bit is logic 0 and its  $\overline{SS}$  pin is at logic 0. To support a multiple-slave system, a logic 1 on the  $\overline{SS}$  pin puts the MISO pin in a high-impedance state.

When enabled, the SPI controls data direction of the MISO pin regardless of the state of the data direction register of the shared I/O port.

MC68HC708MP16 — Rev. 3.1

## 13.13.2 MOSI (Master Out/Slave In)

MOSI is one of the two SPI module pins that transmits serial data. In full duplex operation, the MOSI pin of the master SPI module is connected to the MOSI pin of the slave SPI module. The master SPI simultaneously transmits data from its MOSI pin and receives data on its MISO pin.

When enabled, the SPI controls data direction of the MOSI pin regardless of the state of the data direction register of the shared I/O port.

## 13.13.3 SPSCK (Serial Clock)

The serial clock synchronizes data transmission between master and slave devices. In a master MCU, the SPSCK pin is the clock output. In a slave MCU, the SPSCK pin is the clock input. In full duplex operation, the master and slave MCUs exchange a byte of data in eight serial clock cycles.

When enabled, the SPI controls data direction of the SPSCK pin regardless of the state of the data direction register of the shared I/O port.

# 13.13.4 **SS** (Slave Select)

The  $\overline{SS}$  pin has various functions depending on the current state of the SPI. For an SPI configured as a slave, the  $\overline{SS}$  is used to select a slave. For CPHA = 0, the  $\overline{SS}$  is used to define the start of a transmission. (See 13.6 Transmission Formats.) Since it is used to indicate the start of a transmission, the  $\overline{SS}$  must be toggled high and low between each byte transmitted for the CPHA = 0 format. However, it can remain low between transmissions for the CPHA = 1 format. See Figure 13-12.

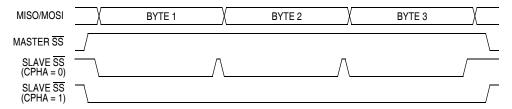

Figure 13-12. CPHA/SS Timing

When an SPI is configured as a slave, the  $\overline{SS}$  pin is always configured as an input. It cannot be used as a general purpose I/O regardless of the state of the MODFEN control bit. However, the MODFEN bit can still prevent the state of the  $\overline{SS}$  from creating a MODF error. (See 13.14.2 SPI Status and Control Register.)

NOTE:

A logic 1 voltage on the  $\overline{SS}$  pin of a slave SPI puts the MISO pin in a high-impedance state. The slave SPI ignores all incoming SPSCK clocks, even if it was already in the middle of a transmission.

When an SPI is configured as a master, the  $\overline{SS}$  input can be used in conjunction with the MODF flag to prevent multiple masters from driving MOSI and SPSCK. (See 13.8.2 Mode Fault Error.) For the state of the  $\overline{SS}$  pin to set the MODF flag, the MODFEN bit in the SPSCK register must be set. If the MODFEN bit is low for an SPI master, the  $\overline{SS}$  pin can be used as a general purpose I/O under the control of the data direction register of the shared I/O port. With MODFEN high, it is an input-only pin to the SPI regardless of the state of the data direction register of the shared I/O port.

The CPU can always read the state of the  $\overline{SS}$  pin by configuring the appropriate pin as an input and reading the port data register. (See **Table 13-3**.)

			J	
SPE	SPMSTR	MODFEN	SPI Configuration	State of SS Logic
0	X <sup>(1)</sup>	Х	Not Enabled	General-purpose I/O; SS ignored by SPI
1	0	X	Slave	Input-only to SPI
1	1	0	Master without MODF	General-purpose I/O; SS ignored by SPI
1	1	1	Master with MODF	Input-only to SPI

Table 13-3. SPI Configuration

## 13.13.5 CGND (Clock Ground)

CGND is the ground return for the serial clock pin, SPSCK, and the ground for the port output buffers. To reduce the ground return path loop and minimize radio frequency (RF) emissions, connect the ground pin of the slave to the CGND pin of the master.

## 13.14 I/O Registers

Three registers control and monitor SPI operation:

- SPI control register (SPCR)
- SPI status and control register (SPSCR)
- SPI data register (SPDR)

<sup>1.</sup> X = don't care

## 13.14.1 SPI Control Register

The SPI control register does the following:

- Enables SPI module interrupt requests
- Selects CPU interrupt requests
- Configures the SPI module as master or slave
- Selects serial clock polarity and phase
- Configures the SPSCK, MOSI, and MISO pins as open-drain outputs
- Enables the SPI module

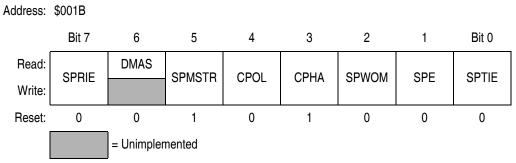

Figure 13-13. SPI Control Register (SPCR)

#### SPRIE — SPI Receiver Interrupt Enable Bit

This read/write bit enables CPU interrupt requests generated by the SPRF bit. The SPRF bit is set when a byte transfers from the shift register to the receive data register. Reset clears the SPRIE bit.

- 1 = SPRF CPU interrupt requests
- 0 = SPRF CPU interrupt requests

## DMAS — DMA Select Bit

This read-only bit has no effect on this version of the SPI. This bit always reads as a 0.

0 = SPRF DMA and SPTE DMA service requests disabled (SPRF CPU and SPTE CPU interrupt requests enabled)

SPMSTR — SPI Master Bit

MC68HC708MP16 - Rev. 3.1

This read/write bit selects master mode operation or slave mode operation. Reset sets the SPMSTR bit.

- 1 = Master mode
- 0 = Slave mode

## CPOL — Clock Polarity Bit

This read/write bit determines the logic state of the SPSCK pin between transmissions. (Figure 13-4 and Figure 13-6.) To transmit data between SPI modules, the SPI modules must have identical CPOL values. Reset clears the CPOL bit.

#### CPHA — Clock Phase Bit

This read/write bit controls the timing relationship between the serial clock and SPI data. (See **Figure 13-4** and **Figure 13-6**.) To transmit data between SPI modules, the SPI modules must have identical CPHA values. When CPHA = 0, the  $\overline{SS}$  pin of the slave SPI module must be set to logic 1 between bytes. (See **Figure 13-12**.) Reset sets the CPHA bit.

#### SPWOM — SPI Wired-OR Mode Bit

This read/write bit disables the pull-up devices on pins SPSCK, MOSI, and MISO so that those pins become open-drain outputs.

- 1 = Wired-OR SPSCK, MOSI, and MISO pins
- 0 = Normal push-pull SPSCK, MOSI, and MISO pins

#### SPE — SPI Enable

This read/write bit enables the SPI module. Clearing SPE causes a partial reset of the SPI. (See 13.10 Resetting the SPI.) Reset clears the SPE bit.

- 1 = SPI module enabled
- 0 = SPI module disabled

#### SPTIE— SPI Transmit Interrupt Enable

This read/write bit enables CPU interrupt requests generated by the SPTE bit. SPTE is set when a byte transfers from the transmit data register to the shift register. Reset clears the SPTIE bit.

- 1 = SPTE CPU interrupt requests enabled
- 0 = SPTE CPU interrupt requests disabled

## 13.14.2 SPI Status and Control Register

The SPI status and control register contains flags to signal the following conditions:

- Receive data register full
- Failure to clear SPRF bit before next byte is received (overflow error)
- Inconsistent logic level on SS pin (mode fault error)
- Transmit data register empty

The SPI status and control register also contains bits that perform the following functions:

- Enable error interrupts
- Enable mode fault error detection
- Select master SPI baud rate

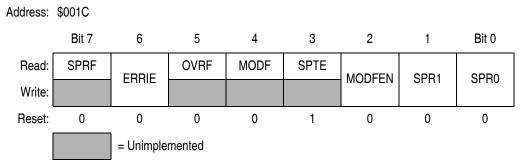

Figure 13-14. SPI Status and Control Register (SPSCR)

#### SPRF — SPI Receiver Full Bit

This clearable, read-only flag is set each time a byte transfers from the shift register to the receive data register. SPRF generates a CPU interrupt request if the SPRIE bit in the SPI control register is set also.

During an SPRF CPU interrupt, the CPU clears SPRF by reading the SPI status and control register with SPRF set and then reading the SPI data register.

Reset clears the SPRF bit.

- 1 = Receive data register full
- 0 = Receive data register not full

MC68HC708MP16 — Rev. 3.1

## ERRIE — Error Interrupt Enable Bit

This read/write bit enables the MODF and OVRF bits to generate CPU interrupt requests. Reset clears the ERRIE bit.

- 1 = MODF and OVRF can generate CPU interrupt requests
- 0 = MODF and OVRF cannot generate CPU interrupt requests

#### OVRF — Overflow Bit

This clearable, read-only flag is set if software does not read the byte in the receive data register before the next full byte enters the shift register. In an overflow condition, the byte already in the receive data register is unaffected, and the byte that shifted in last is lost. Clear the OVRF bit by reading the SPI status and control register with OVRF set and then reading the receive data register. Reset clears the OVRF bit.

- 1 = Overflow
- 0 = No overflow

#### MODF — Mode Fault Bit

This clearable, read-only flag is set in a slave SPI if the  $\overline{SS}$  pin goes high during a transmission with the MODFEN bit set. In a master SPI, the MODF flag is set if the  $\overline{SS}$  pin goes low at any time with the MODFEN bit set. Clear the MODF bit by reading the SPI status and control register (SPSCR) with MODF set and then writing to the SPI control register (SPCR). Reset clears the MODF bit.

- $1 = \overline{SS}$  pin at inappropriate logic level
- $0 = \overline{SS}$  pin at appropriate logic level

#### SPTE — SPI Transmitter Empty Bit

This clearable, read-only flag is set each time the transmit data register transfers a byte into the shift register. SPTE generates an SPTE CPU interrupt request if the SPTIE bit in the SPI control register is set also.

# **NOTE:** Do not write to the SPI data register unless the SPTE bit is high.

During an SPTE CPU interrupt, the CPU clears the SPTE bit by writing to the transmit data register.

Reset sets the SPTE bit.

- 1 = Transmit data register empty
- 0 = Transmit data register not empty

#### MODFEN — Mode Fault Enable Bit

This read/write bit, when set to 1, allows the MODF flag to be set. If the MODF flag is set, clearing the MODFEN does not clear the MODF flag. If the SPI is enabled as a master and the MODFEN bit is low, then the  $\overline{SS}$  pin is available as a general purpose I/O.

If the MODFEN bit is set, then this pin is not available as a general purpose I/O. When the SPI is enabled as a slave, the SS pin is not available as a general purpose I/O regardless of the value of MODFEN. (See 13.13.4 SS (Slave Select).)

If the MODFEN bit is low, the level of the  $\overline{SS}$  pin does not affect the operation of an enabled SPI configured as a master. For an enabled SPI configured as a slave, having MODFEN low only prevents the MODF flag from being set. It does not affect any other part of SPI operation. (See 13.8.2 Mode Fault Error.)

#### SPR1 and SPR0 — SPI Baud Rate Select Bits

In master mode, these read/write bits select one of four baud rates as shown in **Table 13-4**. SPR1 and SPR0 have no effect in slave mode. Reset clears SPR1 and SPR0.

**Table 13-4. SPI Master Baud Rate Selection** 

SPR1:SPR0	Baud Rate Divisor (BD)
00	2
01	8
10	32
11	128

Use the following formula to calculate the SPI baud rate:

Baud rate = 
$$\frac{CGMOUT}{2 \times BD}$$

where:

CGMOUT = base clock output of the clock generator module (CGM) BD = baud rate divisor

MC68HC708MP16 — Rev. 3.1

## 13.14.3 SPI Data Register

The SPI data register consists of the read-only receive data register and the write-only transmit data register. Writing to the SPI data register writes data into the transmit data register. Reading the SPI data register reads data from the receive data register. The transmit data and receive data registers are separate registers that can contain different values. (See Figure 13-1.)

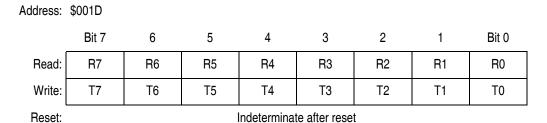

Figure 13-15. SPI Data Register (SPDR)

R7:R0/T7:T0 — Receive/Transmit Data Bits

**NOTE:** Do not use read-modify-write instructions on the SPI data register since the register read is not the same as the register written.

## 14.2 Introduction

This section describes the serial communications interface module (SCI, Version D), which allows high-speed asynchronous communications with peripheral devices and other MCUs.

## 14.3 Features

Features of the SCI module include:

- Full duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- 32 programmable baud rates
- Programmable 8-bit or 9-bit character length
- Separately enabled transmitter and receiver
- Separate receiver and transmitter cpu interrupt requests
- Separate receiver and transmitter
- Programmable transmitter output polarity
- Two receiver wake-up methods:
  - Idle line wake-up
  - Address mark wake-up

- Interrupt-driven operation with eight interrupt flags:
  - Transmitter empty
  - Transmission complete
  - Receiver full
  - Idle receiver input
  - Receiver overrun
  - Noise error
  - Framing error
  - Parity error
- Receiver framing error detection
- Hardware parity checking
- 1/16 bit-time noise detection

## 14.4 Functional Description

Figure 14-1 shows the structure of the SCI module. The SCI allows full-duplex, asynchronous, NRZ serial communication among the MCU and remote devices, including other MCUs. The transmitter and receiver of the SCI operate independently, although they use the same baud rate generator. During normal operation, the CPU monitors the status of the SCI, writes the data to be transmitted, and processes received data.

# Serial Communications Interface Module (SCI)

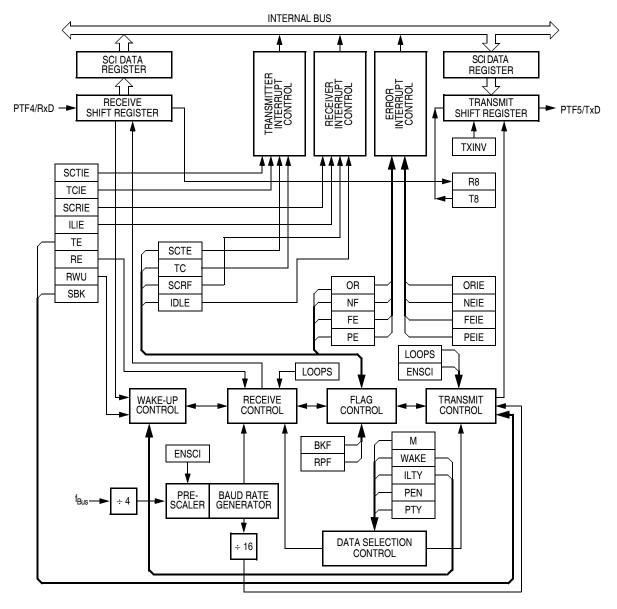

Figure 14-1. SCI Module Block Diagram

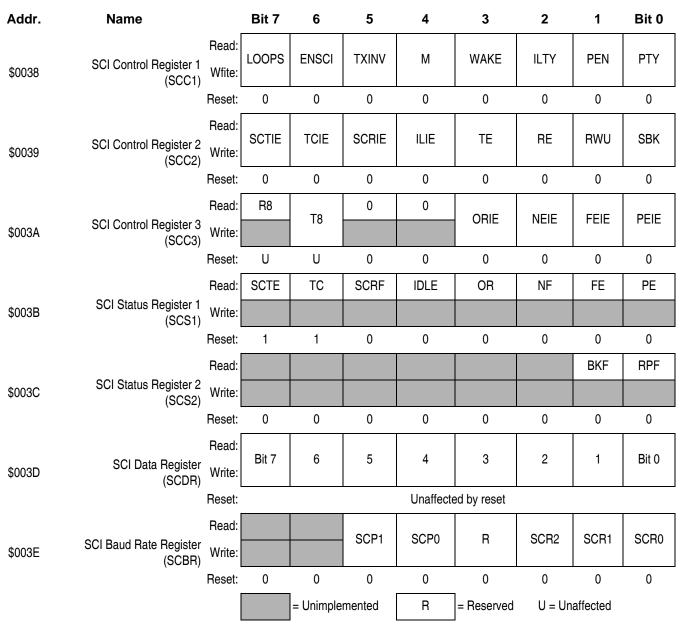

Figure 14-2. SCI I/O Register Summary

# **Serial Communications Interface Module (SCI)**

#### 14.4.1 Data Format

The SCI uses the standard non-return-to-zero mark/space data format illustrated in **Figure 14-3**.

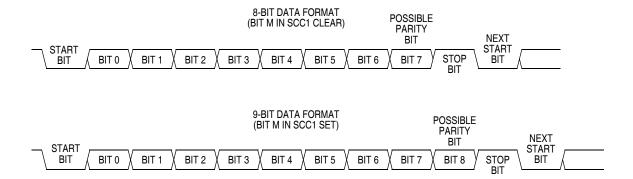

Figure 14-3. SCI Data Formats

#### 14.4.2 Transmitter

Figure 14-4 shows the structure of the SCI transmitter.

## 14.4.2.1 Character Length

The transmitter can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCC1) determines character length. When transmitting 9-bit data, bit T8 in SCI control register 3 (SCC3) is the ninth bit (bit 8).

#### 14.4.2.2 Character Transmission

During an SCI transmission, the transmit shift register shifts a character out to the PTF5/TxD pin. The SCI data register (SCDR) is the write-only buffer between the internal data bus and the transmit shift register. To initiate an SCI transmission:

- 1. Enable the SCI by writing a logic 1 to the enable SCI bit (ENSCI) in SCI control register 1 (SCC1).
- 2. Enable the transmitter by writing a logic 1 to the transmitter enable bit (TE) in SCI control register 2 (SCC2).
- 3. Clear the SCI transmitter empty bit by first reading SCI status register 1 (SCS1) and then writing to the SCDR.
- 4. Repeat step 3 for each subsequent transmission.

At the start of a transmission, transmitter control logic automatically loads the transmit shift register with a preamble of logic 1s. After the preamble shifts out, control logic transfers the SCDR data into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit position of the transmit shift register. A logic 1 stop bit goes into the most significant bit position.

The SCI transmitter empty bit, SCTE, in SCS1 becomes set when the SCDR transfers a byte to the transmit shift register. The SCTE bit indicates that the SCDR can accept new data from the internal data bus. If the SCI transmit interrupt enable bit, SCTIE, in SCC2 is also set, the SCTE bit generates a transmitter CPU interrupt request.

When the transmit shift register is not transmitting a character, the PTF5/TxD pin goes to the idle condition, logic 1. If at any time software clears the ENSCI bit in SCI control register 1 (SCC1), the transmitter and receiver relinquish control of the port F pins.

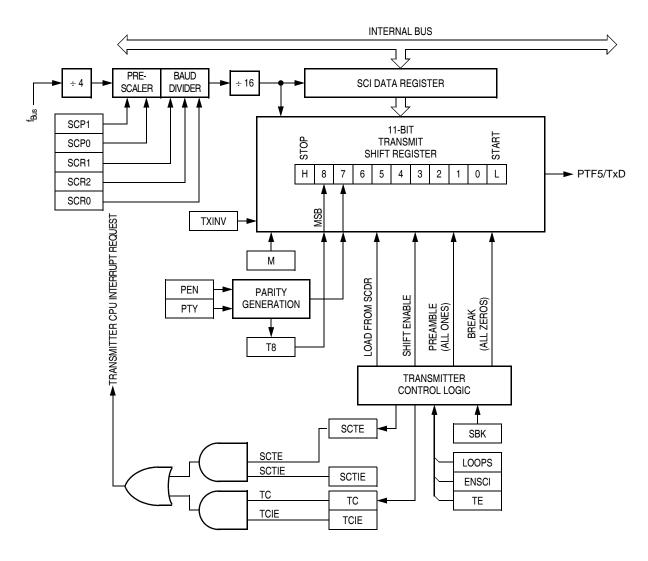

Figure 14-4. SCI Transmitter

#### 14.4.2.3 Break Characters

Writing a logic 1 to the send break bit, SBK, in SCC2 loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on the M bit in SCC1. As long as SBK is at logic 1, transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next character.

The SCI recognizes a break character when a start bit is followed by 8 or 9 logic 0 data bits and a logic 0 where the stop bit should be. Receiving a break character has the following effects on SCI registers:

- Sets the framing error bit (FE) in SCS1
- Sets the SCI receiver full bit (SCRF) in SCS1
- Clears the SCI data register (SCDR)
- Clears the R8 bit in SCC3
- Sets the break flag bit (BKF) in SCS2
- May set the overrun (OR), noise flag (NF), parity error (PE), or reception in progress flag (RPF) bits

#### 14.4.2.4 Idle Characters

An idle character contains all logic 1s and has no start, stop, or parity bit. Idle character length depends on the M bit in SCC1. The preamble is a synchronizing idle character that begins every transmission.

If the TE bit is cleared during a transmission, the PTF5/TxD pin becomes idle after completion of the transmission in progress. Clearing and then setting the TE bit during a transmission queues an idle character to be sent after the character currently being transmitted.

NOTE:

When queueing an idle character, return the TE bit to logic 1 before the stop bit of the current character shifts out to the PTF5/TxD pin. Setting

MC68HC708MP16 — Rev. 3.1

TE after the stop bit appears on PTF5/TxD causes data previously written to the SCDR to be lost.

A good time to toggle the TE bit is when the SCTE bit becomes set and just before writing the next byte to the SCDR.

#### 14.4.2.5 Inversion of Transmitted Output

The transmit inversion bit (TXINV) in SCI control register 1 (SCC1) reverses the polarity of transmitted data. All transmitted values, including idle, break, start, and stop bits, are inverted when TXINV is at logic 1. (See 14.8.1 SCI Control Register 1.)

#### 14.4.2.6 Transmitter Interrupts

The following conditions can generate CPU interrupt requests from the SCI transmitter:

- SCI transmitter empty (SCTE) The SCTE bit in SCS1 indicates
  that the SCDR has transferred a character to the transmit shift
  register. SCTE can generate a transmitter CPU interrupt request.
  Setting the SCI transmit interrupt enable bit, SCTIE, in SCC2
  enables the SCTE bit to generate transmitter CPU interrupt
  requests.
- Transmission complete (TC) The TC bit in SCS1 indicates that
  the transmit shift register and the SCDR are empty and that no
  break or idle character has been generated. The transmission
  complete interrupt enable bit, TCIE, in SCC2 enables the TC bit to
  generate transmitter CPU interrupt requests.

#### 14.4.3 Receiver

Figure 14-5 shows the structure of the SCI receiver.

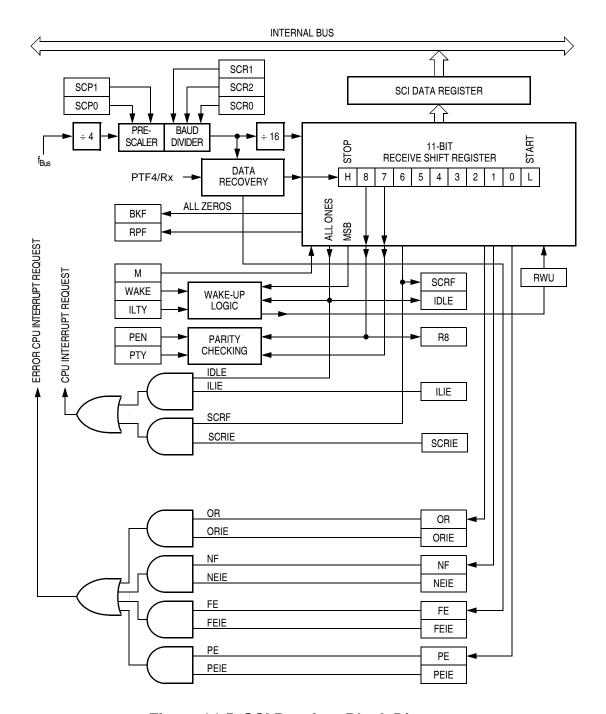

Figure 14-5. SCI Receiver Block Diagram

MC68HC708MP16 - Rev. 3.1

#### 14.4.3.1 Character Length

The receiver can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCC1) determines character length. When receiving 9-bit data, bit R8 in SCI control register 2 (SCC2) is the ninth bit (bit 8). When receiving 8-bit data, bit R8 is a copy of the eighth bit (bit 7).

#### 14.4.3.2 Character Reception

During an SCI reception, the receive shift register shifts characters in from the PTF4/RxD pin. The SCI data register (SCDR) is the read-only buffer between the internal data bus and the receive shift register.

After a complete character shifts into the receive shift register, the data portion of the character transfers to the SCDR. The SCI receiver full bit, SCRF, in SCI status register 1 (SCS1) becomes set, indicating that the received byte can be read. If the SCI receive interrupt enable bit, SCRIE, in SCC2 is also set, the SCRF bit generates a receiver CPU interrupt request.

# 14.4.3.3 Data Sampling

The receiver samples the PTF4/RxD pin at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock is resynchronized at the following times (see **Figure 14-6**):

- After every start bit
- After the receiver detects a data bit change from logic 1 to logic 0
  (after the majority of data bit samples at RT8, RT9, and RT10
  return a valid logic 1 and the majority of the next RT8, RT9, and
  RT10 samples return a valid logic 0)

To locate the start bit, data recovery logic does an asynchronous search for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

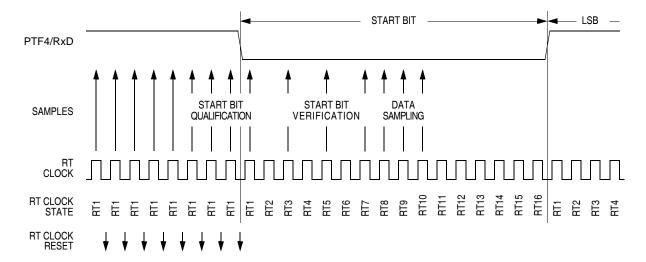

Figure 14-6. Receiver Data Sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7. **Table 14-1** summarizes the results of the start bit verification samples.

**Table 14-1. Start Bit Verification** 

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

MC68HC708MP16 - Rev. 3.1

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. **Table 14-2** summarizes the results of the data bit samples.

Table 14-2. Data Bit Recovery

RT8, RT9, and RT10 Samples	Data Bit Determination	Noise Flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

NOTE:

The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (NF) is set and the receiver assumes that the bit is a start bit.

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. **Table 14-3** summarizes the results of the stop bit samples.

Table 14-3. Stop Bit Recovery

RT8, RT9, and RT10 Samples	Framing Error Flag	Noise Flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

#### 14.4.3.4 Framing Errors

If the data recovery logic does not detect a logic 1 where the stop bit should be in an incoming character, it sets the framing error bit, FE, in SCS1. The FE flag is set at the same time that the SCRF bit is set. A break character that has no stop bit also sets the FE bit.

#### 14.4.3.5 Receiver Wake-Up

So that the MCU can ignore transmissions intended only for other receivers in multiple-receiver systems, the receiver can be put into a standby state. Setting the receiver wake-up bit, RWU, in SCC2 puts the receiver into a standby state during which receiver interrupts are disabled.

Depending on the state of the WAKE bit in SCC1, either of two conditions on the PTF4/RxD pin can bring the receiver out of the standby state:

- Address mark An address mark is a logic 1 in the most significant bit position of a received character. When the WAKE bit is set, an address mark wakes the receiver from the standby state by clearing the RWU bit. The address mark also sets the SCI receiver full bit, SCRF. Software can then compare the character containing the address mark to the user-defined address of the receiver. If they are the same, the receiver remains awake and processes the characters that follow. If they are not the same, software can set the RWU bit and put the receiver back into the standby state.
- Idle input line condition When the WAKE bit is clear, an idle character on the PTF4/RxD pin wakes the receiver from the standby state by clearing the RWU bit. The idle character that wakes the receiver does not set the receiver idle bit, IDLE, or the SCI receiver full bit, SCRF. The idle line type bit, ILTY, determines whether the receiver begins counting logic 1s as idle character bits after the start bit or after the stop bit.

**NOTE:** Clearing the WAKE bit after the PTF4/RxD pin has been idle can cause the receiver to wake up immediately.

MC68HC708MP16 - Rev. 3.1

#### 14.4.3.6 Receiver Interrupts

The following sources can generate CPU interrupt requests from the SCI receiver:

- SCI receiver full (SCRF) The SCRF bit in SCS1 indicates that
  the receive shift register has transferred a character to the SCDR.
  SCRF can generate a receiver CPU interrupt request. Setting the
  SCI receive interrupt enable bit, SCRIE, in SCC2 enables the
  SCRF bit to generate receiver CPU interrupts.
- Idle input (IDLE) The IDLE bit in SCS1 indicates that 10 or 11 consecutive logic 1s shifted in from the PTF4/RxD pin. The idle line interrupt enable bit, ILIE, in SCC2 enables the IDLE bit to generate CPU interrupt requests.

#### 14.4.3.7 Error Interrupts

The following receiver error flags in SCS1 can generate CPU interrupt requests:

- Receiver overrun (OR) The OR bit indicates that the receive shift register shifted in a new character before the previous character was read from the SCDR. The previous character remains in the SCDR, and the new character is lost. The overrun interrupt enable bit, ORIE, in SCC3 enables OR to generate SCI error CPU interrupt requests.
- Noise flag (NF) The NF bit is set when the SCI detects noise on incoming data or break characters, including start, data, and stop bits. The noise error interrupt enable bit, NEIE, in SCC3 enables NF to generate SCI error CPU interrupt requests.
- Framing error (FE) The FE bit in SCS1 is set when a logic 0 occurs where the receiver expects a stop bit. The framing error interrupt enable bit, FEIE, in SCC3 enables FE to generate SCI error CPU interrupt requests.
- Parity error (PE) The PE bit in SCS1 is set when the SCI detects a parity error in incoming data. The parity error interrupt enable bit, PEIE, in SCC3 enables PE to generate SCI error CPU interrupt requests.

#### 14.5 Wait Mode

The WAIT and STOP instructions put the MCU in low-power-consumption standby modes.

The SCI module remains active after the execution of a WAIT instruction. In wait mode the SCI module registers are not accessible by the CPU. Any enabled CPU interrupt request from the SCI module can bring the MCU out of wait mode.

If SCI module functions are not required during wait mode, reduce power consumption by disabling the module before executing the WAIT instruction.

# 14.6 SCI During Break Module Interrupts

The system integration module (SIM) controls whether status bits in other modules can be cleared during interrupts generated by the break module. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state.

To allow software to clear status bits during a break interrupt, write a logic 1 to the BCFE bit. If a status bit is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect status bits during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), software can read and write I/O registers during the break state without affecting status bits. Some status bits have a two-step read/write clearing procedure. If software does the first step on such a bit before the break, the bit cannot change during the break state as long as BCFE is at logic 0. After the break, doing the second step clears the status bit.

# 14.7 I/O Signals

Port F shares two of its pins with the SCI module. The two SCI I/O pins are:

- PTF5/TxD Transmit data
- PTF4/RxD Receive data

#### 14.7.1 PTF5/TxD (Transmit Data)

The PTF5/TxD pin is the serial data output from the SCI transmitter. The SCI shares the PTF5/TxD pin with port F. When the SCI is enabled, the PTF5/TxD pin is an output regardless of the state of the DDRF5 bit in data direction register F (DDRF).

#### 14.7.2 PTF4/RxD (Receive Data)

The PTF4/RxD pin is the serial data input to the SCI receiver. The SCI shares the PTF4/RxD pin with port F. When the SCI is enabled, the PTF4/RxD pin is an input regardless of the state of the DDRF4 bit in data direction register F (DDRF).

# 14.8 I/O Registers

The following I/O registers control and monitor SCI operation:

- SCI control register 1 (SCC1)
- SCI control register 2 (SCC2)
- SCI control register 3 (SCC3)
- SCI status register 1 (SCS1)
- SCI status register 2 (SCS2)
- SCI data register (SCDR)
- SCI baud rate register (SCBR)

#### 14.8.1 SCI Control Register 1

SCI control register 1:

- Enables loop mode operation
- Enables the SCI
- Controls output polarity
- Controls character length
- Controls SCI wake-up method
- Controls idle character detection
- Enables parity function
- Controls parity type

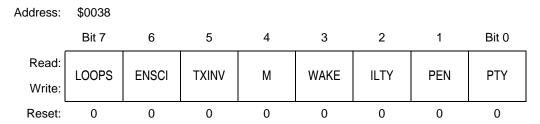

Figure 14-7. SCI Control Register 1 (SCC1)

#### LOOPS — Loop Mode Select Bit

This read/write bit enables loop mode operation. In loop mode the PTE6/RxD pin is disconnected from the SCI, and the transmitter output goes into the receiver input. Both the transmitter and the receiver must be enabled to use loop mode. Reset clears the LOOPS bit.

1 = Loop mode enabled

0 = Normal operation enabled

#### ENSCI — Enable SCI Bit

This read/write bit enables the SCI and the SCI baud rate generator. Clearing ENSCI sets the SCTE and TC bits in SCI status register 1 and disables transmitter interrupts. Reset clears the ENSCI bit.

1 = SCI enabled

0 = SCI disabled

MC68HC708MP16 — Rev. 3.1

#### TXINV — Transmit Inversion Bit

This read/write bit reverses the polarity of transmitted data. Reset clears the TXINV bit.

- 1 = Transmitter output inverted
- 0 = Transmitter output not inverted

# **NOTE:** Setting the TXINV bit inverts all transmitted values, including idle, break, start, and stop bits.

#### M — Mode (Character Length) Bit

This read/write bit determines whether SCI characters are eight or nine bits long. (See **Table 14-4**.) The ninth bit can serve as an extra stop bit, as a receiver wake-up signal, or as a parity bit. Reset clears the M bit.

- 1 = 9-bit SCI characters
- 0 = 8-bit SCI characters

#### WAKE — Wake-Up Condition Bit

This read/write bit determines which condition wakes up the SCI: a logic 1 (address mark) in the most significant bit position of a received character or an idle condition on the PTE6/RxD pin. Reset clears the WAKE bit.

- 1 = Address mark wake-up
- 0 = Idle line wake-up

#### ILTY — Idle Line Type Bit

This read/write bit determines when the SCI starts counting logic 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit may cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. Reset clears the ILTY bit.

- 1 = Idle character bit count begins after stop bit
- 0 = Idle character bit count begins after start bit

#### PEN — Parity Enable Bit

This read/write bit enables the SCI parity function. (See **Table 14-4**.) When enabled, the parity function inserts a parity bit in the most significant bit position. (See **Figure 14-3**.) Reset clears the PEN bit.

- 1 = Parity function enabled
- 0 = Parity function disabled

#### PTY — Parity Bit

This read/write bit determines whether the SCI generates and checks for odd parity or even parity. (See **Table 14-4**.) Reset clears the PTY bit.

- 1 = Odd parity
- 0 = Even parity

# **NOTE:** Changing the PTY bit in the middle of a transmission or reception can generate a parity error.

**Control Bits Character Format** Start Data Stop Character PEN:PTY М **Parity Bits Bits** Bits Length 0 ΩX 1 8 None 1 10 bits 1 0X 1 9 None 1 11 bits 0 7 10 1 Even 1 10 bits 7 0 1 1 11 Odd 10 bits 1 10 1 8 1 11 bits Even 1 8 1 11 Odd 1 11 bits

**Table 14-4. Character Format Selection** 

#### 14.8.2 SCI Control Register 2

SCI control register 2:

- Enables the following CPU interrupt requests:
  - Enables the SCTE bit to generate transmitter CPU interrupt requests
  - Enables the TC bit to generate transmitter CPU interrupt requests
  - Enables the SCRF bit to generate receiver CPU interrupt requests
  - Enables the IDLE bit to generate receiver CPU interrupt requests
- Enables the transmitter
- Enables the receiver
- Enables SCI wake-up
- Transmits SCI break characters

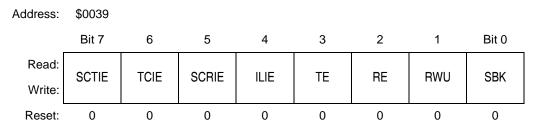

Figure 14-8. SCI Control Register 2 (SCC2)

SCTIE — SCI Transmit Interrupt Enable Bit

This read/write bit enables the SCTE bit to generate SCI transmitter CPU interrupt requests. Setting the SCTIE bit in SCC3 enables SCTE CPU interrupt requests. Reset clears the SCTIE bit.

1 = SCTE enabled to generate CPU interrupt

0 = SCTE not enabled to generate CPU interrupt

#### TCIE — Transmission Complete Interrupt Enable Bit

This read/write bit enables the TC bit to generate SCI transmitter CPU interrupt requests. Reset clears the TCIE bit.

- 1 = TC enabled to generate CPU interrupt requests
- 0 = TC not enabled to generate CPU interrupt requests

#### SCRIE — SCI Receive Interrupt Enable Bit

This read/write bit enables the SCRF bit to generate SCI receiver CPU interrupt requests. Setting the SCRIE bit in SCC3 enables the SCRF bit to generate CPU interrupt requests. Reset clears the SCRIE bit.

- 1 = SCRF enabled to generate CPU interrupt
- 0 = SCRF not enabled to generate CPU interrupt

#### ILIE — Idle Line Interrupt Enable Bit

This read/write bit enables the IDLE bit to generate SCI receiver CPU interrupt requests. Reset clears the ILIE bit.

- 1 = IDLE enabled to generate CPU interrupt requests
- 0 = IDLE not enabled to generate CPU interrupt requests

#### TE — Transmitter Enable Bit

Setting this read/write bit begins the transmission by sending a preamble of ten or eleven logic 1s from the transmit shift register to the PTF5/TxD pin. If software clears the TE bit, the transmitter completes any transmission in progress before the PTF5/TxD returns to the idle condition (logic 1). Clearing and then setting TE during a transmission queues an idle character to be sent after the character currently being transmitted. Reset clears the TE bit.

- 1 = Transmitter enabled
- 0 = Transmitter disabled

# **NOTE:** Writing to the TE bit is not allowed when the enable SCI bit (ENSCI) is clear. ENSCI is in SCI control register 1.

#### RE — Receiver Enable Bit

Setting this read/write bit enables the receiver. Clearing the RE bit disables the receiver but does not affect receiver interrupt flag bits. Reset clears the RE bit.

- 1 = Receiver enabled
- 0 = Receiver disabled

# **NOTE:** Writing to the RE bit is not allowed when the enable SCI bit (ENSCI) is clear. ENSCI is in SCI control register 1.

#### RWU — Receiver Wake-Up Bit

This read/write bit puts the receiver in a standby state during which receiver interrupts are disabled. The WAKE bit in SCC1 determines whether an idle input or an address mark brings the receiver out of the standby state and clears the RWU bit. Reset clears the RWU bit.

- 1 = Standby state
- 0 = Normal operation

#### SBK — Send Break Bit

Setting and then clearing this read/write bit transmits a break character followed by a logic 1. The logic 1 after the break character guarantees recognition of a valid start bit. If SBK remains set, the transmitter continuously transmits break characters with no logic 1s between them. Reset clears the SBK bit.

- 1 = Transmit break characters
- 0 = No break characters being transmitted

# **NOTE:** Do not toggle the SBK bit immediately after setting the SCTE bit. Toggling SBK too early causes the SCI to send a break character instead of a preamble.

#### 14.8.3 SCI Control Register 3

#### SCI control register 3:

- Stores the ninth SCI data bit received and the ninth SCI data bit to be transmitted
- Enables SCI receiver full (SCRF)
- Enables SCI transmitter empty (SCTE)
- Enables the following interrupts:
  - Receiver overrun interrupts
  - Noise error interrupts
  - Framing error interrupts
  - Parity error interrupts

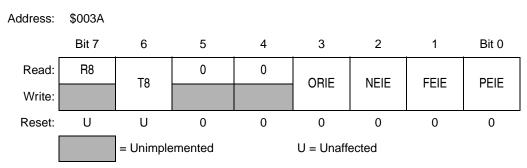

Figure 14-9. SCI Control Register 3 (SCC3)

#### R8 — Received Bit 8

When the SCI is receiving 9-bit characters, R8 is the read-only ninth bit (bit 8) of the received character. R8 is received at the same time that the SCDR receives the other 8 bits.

When the SCI is receiving 8-bit characters, R8 is a copy of the eighth bit (bit 7). Reset has no effect on the R8 bit.

#### T8 — Transmitted Bit 8

When the SCI is transmitting 9-bit characters, T8 is the read/write ninth bit (bit 8) of the transmitted character. T8 is loaded into the transmit shift register at the same time that the SCDR is loaded into the transmit shift register. Reset has no effect on the T8 bit.

MC68HC708MP16 — Rev. 3.1

ORIE — Receiver Overrun Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the receiver overrun bit, OR.

- 1 = SCI error CPU interrupt requests from OR bit enabled
- 0 = SCI error CPU interrupt requests from OR bit disabled

#### NEIE — Receiver Noise Error Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the noise error bit, NE. Reset clears NEIE.

- 1 = SCI error CPU interrupt requests from NE bit enabled
- 0 = SCI error CPU interrupt requests from NE bit disabled

#### FEIE — Receiver Framing Error Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the framing error bit, FE. Reset clears FEIE.

- 1 = SCI error CPU interrupt requests from FE bit enabled
- 0 = SCI error CPU interrupt requests from FE bit disabled

#### PEIE — Receiver Parity Error Interrupt Enable Bit

This read/write bit enables SCI receiver CPU interrupt requests generated by the parity error bit, PE. (See 14.8.4 SCI Status Register 1.) Reset clears PEIE.

- 1 = SCI error CPU interrupt requests from PE bit enabled
- 0 = SCI error CPU interrupt requests from PE bit disabled

## 14.8.4 SCI Status Register 1

SCI status register 1 contains flags to signal these conditions:

- Transfer of SCDR data to transmit shift register complete
- Transmission complete
- Transfer of receive shift register data to SCDR complete
- Receiver input idle
- Receiver overrun
- Noisy data
- Framing error
- Parity error

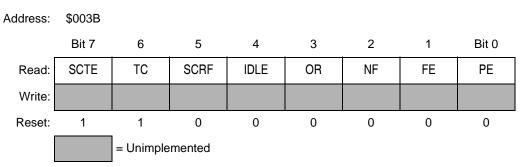

Figure 14-10. SCI Status Register 1 (SCS1)

#### SCTE — SCI Transmitter Empty Bit

This clearable, read-only bit is set when the SCDR transfers a character to the transmit shift register. SCTE can generate an SCI transmitter CPU interrupt request. When the SCTIE bit in SCC2 is set, SCTE generates an SCI transmitter CPU interrupt request. In normal operation, clear the SCTE bit by reading SCS1 with SCTE set and then writing to SCDR. Reset sets the SCTE bit.

- 1 = SCDR data transferred to transmit shift register
- 0 = SCDR data not transferred to transmit shift register

MC68HC708MP16 — Rev. 3.1

#### TC — Transmission Complete Bit

This read-only bit is set when the SCTE bit is set, and no data, preamble, or break character is being transmitted. TC generates an SCI transmitter CPU interrupt request if the TCIE bit in SCC2 is also set. TC is automatically cleared when data, preamble or break is queued and ready to be sent. There may be up to 1.5 transmitter clocks of latency between queueing data, preamble, and break and the transmission actually starting. Reset sets the TC bit.

- 1 = No transmission in progress
- 0 = Transmission in progress

#### SCRF — SCI Receiver Full Bit

This clearable, read-only bit is set when the data in the receive shift register transfers to the SCI data register. SCRF can generate an SCI receiver CPU interrupt request. When the SCRIE bit in SCC2 is set, SCRF generates a CPU interrupt request. In normal operation, clear the SCRF bit by reading SCS1 with SCRF set and then reading the SCDR. Reset clears SCRF.

- 1 = Received data available in SCDR
- 0 = Data not available in SCDR

#### IDLE — Receiver Idle Bit

This clearable, read-only bit is set when ten or eleven consecutive logic 1s appear on the receiver input. IDLE generates an SCI error CPU interrupt request if the ILIE bit in SCC2 is also set. Clear the IDLE bit by reading SCS1 with IDLE set and then reading the SCDR. After the receiver is enabled, it must receive a valid character that sets the SCRF bit before an idle condition can set the IDLE bit. Also, after the IDLE bit has been cleared, a valid character must again set the SCRF bit before an idle condition can set the IDLE bit. Reset clears the IDLE bit.

- 1 = Receiver input idle
- 0 = Receiver input active (or idle since the IDLE bit was cleared)

#### OR — Receiver Overrun Bit

This clearable, read-only bit is set when software fails to read the SCDR before the receive shift register receives the next character. The OR bit generates an SCI error CPU interrupt request if the ORIE bit in SCC3 is also set. The data in the shift register is lost, but the data already in the SCDR is not affected. Clear the OR bit by reading SCS1 with OR set and then reading the SCDR. Reset clears the OR bit.

- 1 = Receive shift register full and SCRF = 1
- 0 = No receiver overrun

Software latency may allow an overrun to occur between reads of SCS1 and SCDR in the flag-clearing sequence. Figure 14-11 shows the normal flag-clearing sequence and an example of an overrun caused by a delayed flag-clearing sequence. The delayed read of SCDR does not clear the OR bit because OR was not set when SCS1 was read. Byte 2 caused the overrun and is lost. The next flag-clearing sequence reads byte 3 in the SCDR instead of byte 2.

In applications that are subject to software latency or in which it is important to know which byte is lost due to an overrun, the flag-clearing routine can check the OR bit in a second read of SCS1 after reading the data register.

#### NF — Receiver Noise Flag Bit

This clearable, read-only bit is set when the SCI detects noise on the PTF4/RxD pin. NF generates an NF CPU interrupt request if the NEIE bit in SCC3 is also set. Clear the NF bit by reading SCS1 and then reading the SCDR. Reset clears the NF bit.

- 1 = Noise detected
- 0 = No noise detected

#### FE — Receiver Framing Error Bit

This clearable, read-only bit is set when a logic 0 is accepted as the stop bit. FE generates an SCI error CPU interrupt request if the FEIE bit in SCC3 also is set. Clear the FE bit by reading SCS1 with FE set and then reading the SCDR. Reset clears the FE bit.

- 1 = Framing error detected
- 0 = No framing error detected

MC68HC708MP16 — Rev. 3.1

## PE — Receiver Parity Error Bit

This clearable, read-only bit is set when the SCI detects a parity error in incoming data. PE generates a PE CPU interrupt request if the PEIE bit in SCC3 is also set. Clear the PE bit by reading SCS1 with PE set and then reading the SCDR. Reset clears the PE bit.

- 1 = Parity error detected
- 0 = No parity error detected

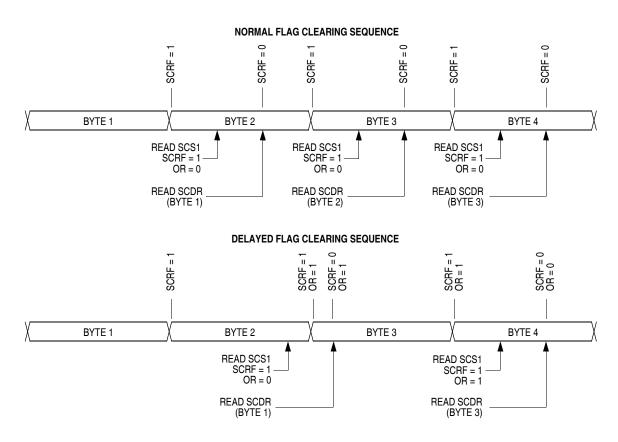

Figure 14-11. Flag Clearing Sequence

#### 14.8.5 SCI Status Register 2

SCI status register 2 contains flags to signal these conditions:

- Break character detected
- Incoming data

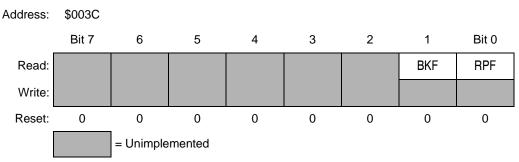

Figure 14-12. SCI Status Register 2 (SCS2)

#### BKF — Break Flag Bit

This clearable, read-only bit is set when the SCI detects a break character on the PTF4/RxD pin. In SCS1, the FE and SCRF bits are also set. In 9-bit character transmissions, the R8 bit in SCC3 is cleared. BKF does not generate a CPU interrupt request. Clear BKF by reading SCS2 with BKF set and then reading the SCDR. Once cleared, BKF can become set again only after logic 1s again appear on the PTF4/RxD pin followed by another break character. Reset clears the BKF bit.

- 1 = Break character detected
- 0 = No break character detected

#### RPF —Reception in Progress Flag Bit

This read-only bit is set when the receiver detects a logic 0 during the RT1 time period of the start bit search. RPF does not generate an interrupt request. RPF is reset after the receiver detects false start bits (usually from noise or a baud rate mismatch, or when the receiver detects an idle character. Polling RPF before disabling the SCI module or entering stop mode can show whether a reception is in progress.

- 1 = Reception in progress
- 0 = No reception in progress

MC68HC708MP16 — Rev. 3.1

#### 14.8.6 SCI Data Register

The SCI data register is the buffer between the internal data bus and the receive and transmit shift registers. Reset has no effect on data in the SCI data register.

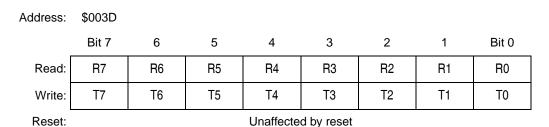

Figure 14-13. SCI Data Register (SCDR)

R7/T7:R0/T0 — Receive/Transmit Data Bits

Reading address \$003D accesses the read-only received data bits, R7:R0. Writing to address \$003D writes the data to be transmitted, T7:T0. Reset has no effect on the SCI data register.

#### 14.8.7 SCI Baud Rate Register

The baud rate register selects the baud rate for both the receiver and the transmitter.

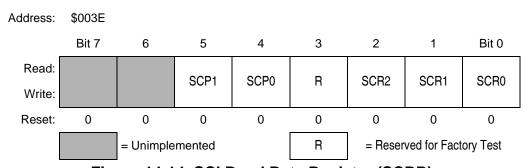

Figure 14-14. SCI Baud Rate Register (SCBR)

SCP1 and SCP0 — SCI Baud Rate Prescaler Bits

These read/write bits select the baud rate prescaler divisor as shown in **Table 14-5**. Reset clears SCP1 and SCP0.

Technical Data

MC68HC708MP16 — Rev. 3.1

Table 14-5. SCI Baud Rate Prescaling

SCP1:SCP0	Prescaler Divisor (PD)
00	1
01	3
10	4
11	13

SCR2-SCR0 — SCI Baud Rate Select Bits

These read/write bits select the SCI baud rate divisor as shown in **Table 14-6**. Reset clears SCR2–SCR0.

Table 14-6. SCI Baud Rate Selection

SCR2:SCR1:SCR0	Baud Rate Divisor (BD)
000	1
001	2
010	4
011	8
100	16
101	32
110	64
111	128

Use this formula to calculate the SCI baud rate:

Baud rate = 
$$\frac{f_{Bus}}{64 \times PD \times BD}$$

where:

f<sub>Bus</sub> = bus frequency

PD = prescaler divisor

BD = baud rate divisor

**Table 14-7** shows the SCI baud rates that can be generated with a 4.9152-MHz crystal.

MC68HC708MP16 - Rev. 3.1

**Table 14-7. SCI Baud Rate Selection Examples**

#### 15.2 Introduction

Thirty-seven bidirectional input-output (I/O) pins and seven input pins form eight parallel ports. All I/O pins are programmable as inputs or outputs.

NOTE:

Connect any unused I/O pins to an appropriate logic level, either  $V_{DD}$  or  $V_{SS}$ . Although the I/O ports do not require termination for proper operation, termination reduces excess current consumption and the possibility of electrostatic damage.

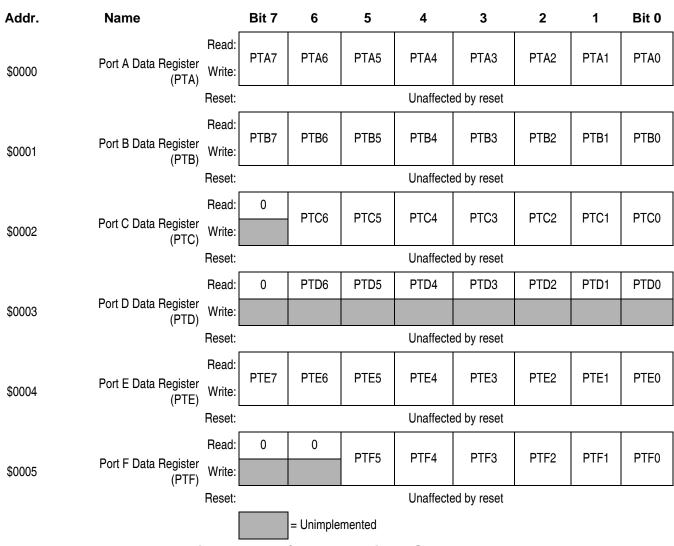

Figure 15-1. I/O Port Register Summary

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

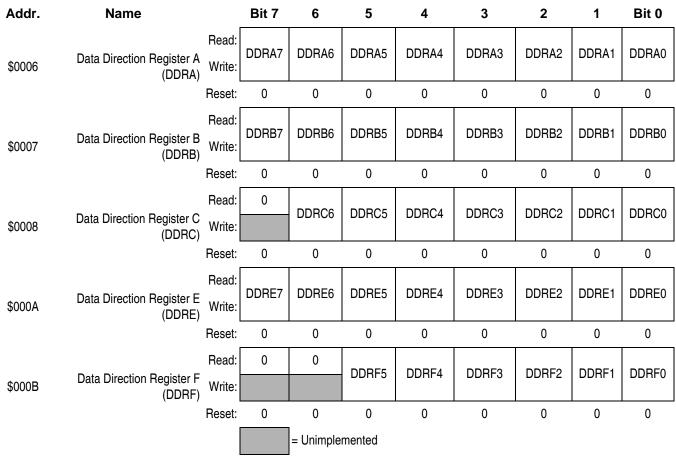

Figure 15-1. I/O Port Register Summary (Continued)

## 15.3 Port A

Port A is an 8-bit general-purpose bidirectional I/O port.

#### 15.3.1 Port A Data Register

The port A data register (PTA) contains a data latch for each of the eight port A pins.

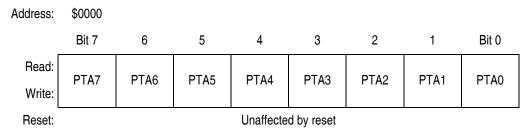

Figure 15-2. Port A Data Register (PTA)

#### PTA[7:0] — Port A Data Bits

These read/write bits are software programmable. Data direction of each port A pin is under the control of the corresponding bit in data direction register A. Reset has no effect on port A data.

#### 15.3.2 Data Direction Register A

Data direction register A (DDRA) determines whether each port A pin is an input or an output. Writing a logic 1 to a DDRA bit enables the output buffer for the corresponding port A pin; a logic 0 disables the output buffer.

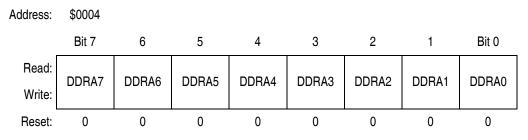

Figure 15-3. Data Direction Register A (DDRA)

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

#### DDRA[7:0] — Data Direction Register A Bits

These read/write bits control port A data direction. Reset clears DDRA[7:0], configuring all port A pins as inputs.

- 1 = Corresponding port A pin configured as output
- 0 = Corresponding port A pin configured as input

# **NOTE:** Avoid glitches on port A pins by writing to the port A data register before changing data direction register A bits from 0 to 1.

Figure 15-4 shows the port A I/O logic.

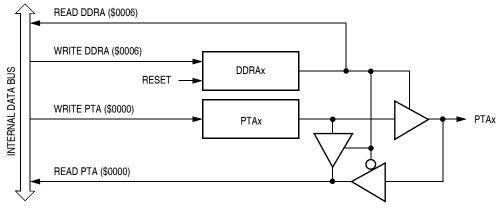

Figure 15-4. Port A I/O Circuit

When bit DDRAx is a logic 1, reading address \$0000 reads the PTAx data latch. When bit DDRAx is a logic 0, reading address \$0000 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. **Table 15-1** summarizes the operation of the port A pins.

**Accesses Accesses to PTA DDRA** I/O Pin to DDRA **PTA Bit** Bit Mode Read/Write Write Read  $\chi^{(1)}$ Input, Hi-Z<sup>(2)</sup> PTA[7:0]<sup>(3)</sup> 0 DDRA[7:0] Pin PTA[7:0] 1 Χ Output DDRA[7:0] PTA[7:0]

MC68HC708MP16 — Rev. 3.1

#### 15.4 Port B

Port B is an 8-bit general-purpose bidirectional I/O port that shares its pins with the analog-to-digital convertor module (ADC).

#### 15.4.1 Port B Data Register

The port B data register (PTB) contains a data latch for each of the eight port B pins.

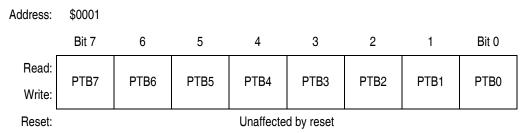

Figure 15-5. Port B Data Register (PTB)

#### PTB[7:0] — Port B Data Bits

These read/write bits are software-programmable. Data direction of each port B pin is under the control of the corresponding bit in data direction register B. Reset has no effect on port B data.

#### 15.4.2 Data Direction Register B

Data direction register B (DDRB) determines whether each port B pin is an input or an output. Writing a logic 1 to a DDRB bit enables the output buffer for the corresponding port B pin; a logic 0 disables the output buffer.

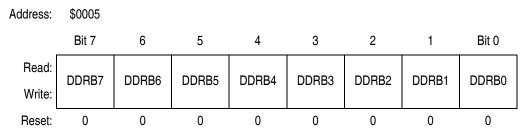

Figure 15-6. Data Direction Register B (DDRB)

Technical Data MC68HC708MP16 — Rev. 3.1

#### DDRB[7:0] — Data Direction Register B Bits

These read/write bits control port B data direction. Reset clears DDRB[7:0], configuring all port B pins as inputs.

- 1 = Corresponding port B pin configured as output
- 0 = Corresponding port B pin configured as input

# **NOTE:** Avoid glitches on port B pins by writing to the port B data register before changing data direction register B bits from 0 to 1.

Figure 15-7 shows the port B I/O logic.

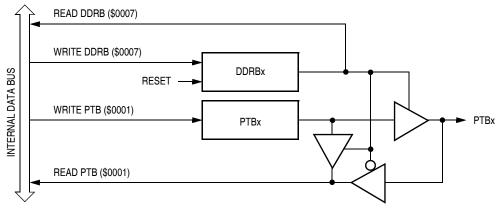

Figure 15-7. Port B I/O Circuit

When bit DDRBx is a logic 1, reading address \$0001 reads the PTBx data latch. When bit DDRBx is a logic 0, reading address \$0001 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. **Table 15-2** summarizes the operation of the port B pins.

Accesses to **Accesses to PTB DDRB DDRB PTB Bit** I/O Pin Mode Bit Read/Write Read Write  $X^{(1)}$ Input, Hi-Z<sup>(2)</sup> PTB[7:0]<sup>(3)</sup> 0 DDRB[7:0] Pin PTB[7:0] 1 Χ Output DDRB[7:0] PTB[7:0]

- 1. X = don't care
- 2. Hi-Z = high impedance
- 3. Writing affects data register, but does not affect input.

MC68HC708MP16 — Rev. 3.1

#### 15.5 Port C

Port C is a 7-bit general-purpose bidirectional I/O port that shares two of its pins with the analog-to-digital convertor module (ADC).

#### 15.5.1 Port C Data Register

The port C data register (PTC) contains a data latch for each of the seven port C pins.

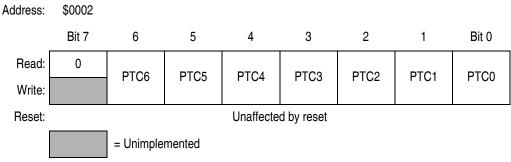

Figure 15-8. Port C Data Register (PTC)

# PTC[6:0] — Port C Data Bits

These read/write bits are software-programmable. Data direction of each port C pin is under the control of the corresponding bit in data direction register C. Reset has no effect on port C data.

### 15.5.2 Data Direction Register C

Data direction register C (DDRC) determines whether each port C pin is an input or an output. Writing a logic 1 to a DDRC bit enables the output buffer for the corresponding port C pin; a logic 0 disables the output buffer.

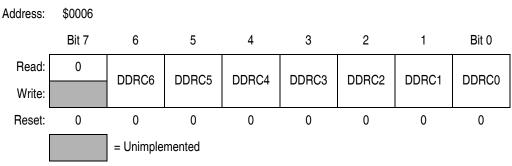

Figure 15-9. Data Direction Register C (DDRC)

DDRC[6:0] — Data Direction Register C Bits

These read/write bits control port C data direction. Reset clears DDRC[6:0], configuring all port C pins as inputs.

- 1 = Corresponding port C pin configured as output
- 0 = Corresponding port C pin configured as input

**NOTE:** Avoid glitches on port C pins by writing to the port C data register before changing data direction register C bits from 0 to 1.

Figure 15-10 shows the port C I/O logic.

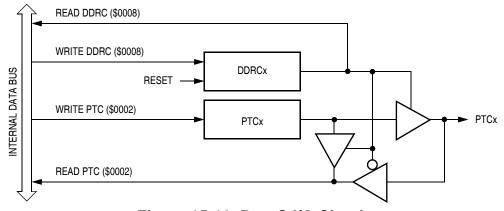

Figure 15-10. Port C I/O Circuit

MC68HC708MP16 — Rev. 3.1

When bit DDRCx is a logic 1, reading address \$0002 reads the PTCx data latch. When bit DDRCx is a logic 0, reading address \$0002 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. **Table 15-3** summarizes the operation of the port C pins.

DDRC Bit	PTC Bit	I/O Pin Mode	Accesses to DDRC	Accesses to PTC	
			Read/Write	Read	Write
0	X <sup>(1)</sup>	Input, Hi-Z <sup>(2)</sup>	DDRC[6:0]	Pin	PTC[6:0] <sup>(3)</sup>
1	Х	Output	DDRC[6:0]	PTC[6:0]	PTC[6:0]

Table 15-3. Port C Pin Functions

#### 15.6 Port D

Port D is a 7-bit input only port that shares its pins with the pulse width modulator for motor control module (PWMMC).

The port D data register (PTD) contains a data latch for each of the seven port pins.

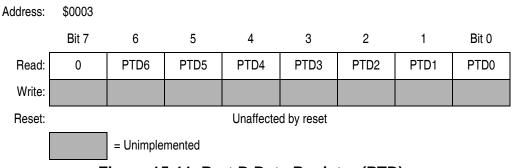

Figure 15-11. Port D Data Register (PTD)

PTD[6:0] — Port D Data Bits

These read/write bits are software programmable. Reset has no effect on port D data.

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

<sup>1.</sup> X = don't care

<sup>2.</sup> Hi-Z = high impedance

<sup>3.</sup> Writing affects data register, but does not affect input.

Figure 15-12 shows the port D input logic.

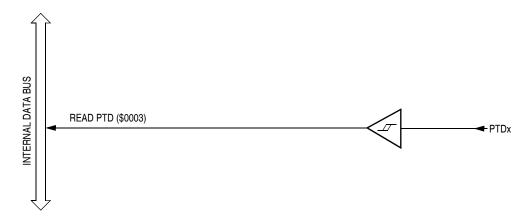

Figure 15-12. Port D Input Circuit

Reading address \$0003 reads the voltage level on the pin. **Table 15-1** summarizes the operation of the port D pins.

**Table 15-4. Port D Pin Functions** 

PTD Bit	Pin Mode	Accesses to PTD		
	FIII WOULE	Read	Write	
X <sup>(1)</sup>	Input, Hi-Z <sup>(2)</sup>	Pin	PTD[6:0] <sup>(3)</sup>	

- 1. X = don't care
- 2. Hi-Z = high impedance
- 3. Writing affects data register, but does not affect input.

## 15.7 Port E

Port E is an 8-bit special function port that shares three of its pins with the timer A interface module (TIMA) and five of its pins with the timer B interface module (TIMB).

#### 15.7.1 Port E Data Register

The port E data register (PTE) contains a data latch for each of the eight port E pins.

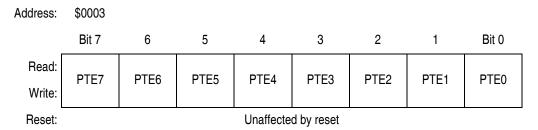

Figure 15-13. Port E Data Register (PTE)

PTE[7:0] — Port E Data Bits

PTE[7:0] are read/write, software-programmable bits. Data direction of each port E pin is under the control of the corresponding bit in data direction register E.

**NOTE:** 

Data direction register E (DDRE) does not affect the data direction of port E pins that are being used by the TIMA or TIMB. However, the DDRE bits always determine whether reading port E returns the states of the latches or the states of the pins.

#### 15.7.2 Data Direction Register E

Data direction register E (DDRE) determines whether each port E pin is an input or an output. Writing a logic 1 to a DDRE bit enables the output buffer for the corresponding port E pin; a logic 0 disables the output buffer.

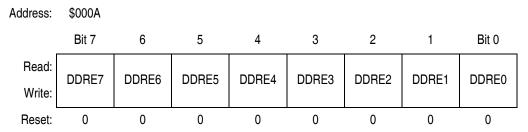

Figure 15-14. Data Direction Register E (DDRE)

DDRE[7:0] — Data Direction Register E Bits

These read/write bits control port E data direction. Reset clears DDRE[7:0], configuring all port E pins as inputs.

- 1 = Corresponding port E pin configured as output
- 0 = Corresponding port E pin configured as input

**NOTE:** Avoid glitches on port E pins by writing to the port E data register before changing data direction register E bits from 0 to 1.

Figure 15-15 shows the port E I/O logic.

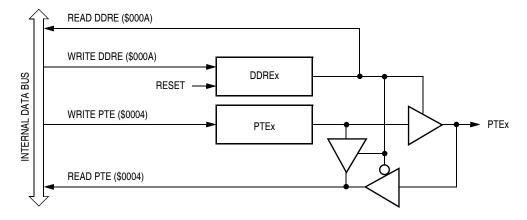

Figure 15-15. Port E I/O Circuit

MC68HC708MP16 - Rev. 3.1

When bit DDREx is a logic 1, reading address \$0004 reads the PTEx data latch. When bit DDREx is a logic 0, reading address \$0004 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. Table 15-3 summarizes the operation of the port E pins.

DDRE Bit	PTE Bit	I/O Pin Mode	Accesses to DDRE	Accesses to PTE	
			Read/Write	Read	Write
0	X <sup>(1)</sup>	Input, Hi-Z <sup>(2)</sup>	DDRE[7:0]	Pin	PTE[7:0] <sup>(3)</sup>
1	Х	Output	DDRE[7:0]	PTE[7:0]	PTE[7:0]

Table 15-5. Port E Pin Functions

#### 15.8 Port F

Port F is a 6-bit special function port that shares four of its pins with the serial peripheral interface module (SPI) and two pins with the serial communications interface (SCI).

#### 15.8.1 Port F Data Register

The port F data register (PTF) contains a data latch for each of the six port F pins.

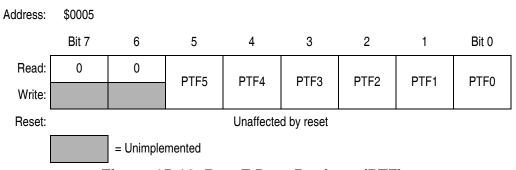

Figure 15-16. Port F Data Register (PTF)

<sup>1.</sup> X = don't care

<sup>2.</sup> Hi-Z = high impedance

<sup>3.</sup> Writing affects data register, but does not affect input.

#### PTF[5:0] — Port F Data Bits

These read/write bits are software programmable. Data direction of each port F pin is under the control of the corresponding bit in data direction register F. Reset has no effect on PTF[5:0].

NOTE:

Data direction register F (DDRF) does not affect the data direction of port F pins that are being used by the SPI or SCI module. However, the DDRF bits always determine whether reading port F returns the states of the latches or the states of the pins.

#### 15.8.2 Data Direction Register F

Data direction register F (DDRF) determines whether each port F pin is an input or an output. Writing a logic 1 to a DDRF bit enables the output buffer for the corresponding port F pin; a logic 0 disables the output buffer.

Figure 15-17. Data Direct Register F (DDRF)

#### DDRF[5:0] — Data Direction Register F Bits

These read/write bits control port F data direction. Reset clears DDRF[5:0], configuring all port F pins as inputs.

- 1 = Corresponding port F pin configured as output
- 0 = Corresponding port F pin configured as input

#### NOTE:

Avoid glitches on port F pins by writing to the port F data register before changing data direction register F bits from 0 to 1.

Figure 15-18 shows the port F I/O logic.

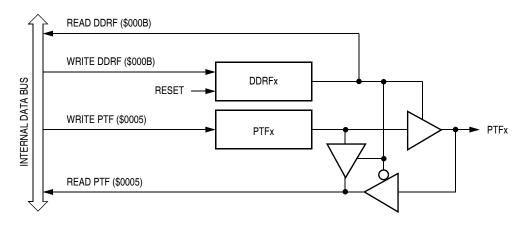

Figure 15-18. Port F I/O Circuit

When bit DDRFx is a logic 1, reading address \$0005 reads the PTFx data latch. When bit DDRFx is a logic 0, reading address \$0005 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. **Table 15-3** summarizes the operation of the port F pins.

**Table 15-6. Port F Pin Functions** 

DDRF Bit	PTF Bit	I/O Pin Mode	Accesses to DDRF	Accesses to PTF	
			Read/Write	Read	Write
0	X <sup>(1)</sup>	Input, Hi-Z <sup>(2)</sup>	DDRF[6:0]	Pin	PTF[6:0] <sup>(3)</sup>
1	Х	Output	DDRF[6:0]	PTF[6:0]	PTF[6:0]

- 1. X = don't care
- 2. Hi-Z = high impedance
- 3. Writing affects data register, but does not affect input.

16.9	COP Module During Break Mode

## 16.2 Introduction

This section describes the computer operating properly module (COP, Version B), a free-running counter that generates a reset if allowed to overflow. The COP module helps software recover from runaway code. Prevent a COP reset by periodically clearing the COP counter.

# 16.3 Functional Description

Figure 16-1 shows the structure of the COP module.

NOTE: See 7.4.2 Active Resets from Internal Sources.

Figure 16-1. COP Block Diagram

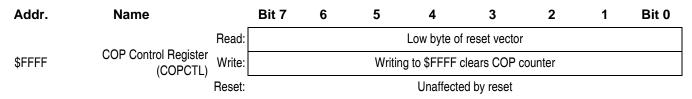

Figure 16-2. COP I/O Register Summary

The COP counter is a free-running 6-bit counter preceded by the 13-bit system integration module (SIM) counter. If not cleared by software, the COP counter overflows and generates an asynchronous reset after  $2^{18} - 2^4$  CGMXCLK cycles. With a 4.9152-MHz crystal, the COP timeout period is 53.3 ms. Writing any value to location \$FFFF before overflow occurs clears the COP counter and prevents reset.

A COP reset pulls the RST pin low for 32 CGMXCLK cycles and sets the COP bit in the SIM reset status register (SRSR) (see **7.7.3 SIM Reset Status Register**).

#### NOTE:

Place COP clearing instructions in the main program and not in an interrupt subroutine. Such an interrupt subroutine could keep the COP from generating a reset even while the main program is not working properly.

# 16.4 I/O Signals

The following paragraphs describe the signals shown in **Figure 16-1**.

#### 16.4.1 CGMXCLK

CGMXCLK is the crystal oscillator output signal. CGMXCLK frequency is equal to the crystal frequency.

#### 16.4.2 COPCTL Write

Writing any value to the COP control register (COPCTL) (see 16.5 COP Control Register) clears the COP counter and clears bits 12 through 4 of the SIM counter. Reading the COP control register returns the reset vector.

#### 16.4.3 Power-On Reset

The power-on reset (POR) circuit in the SIM clears the SIM counter 4096 CGMXCLK cycles after power-up.

MC68HC708MP16 — Rev. 3.1

# **Computer Operating Properly (COP)**

#### 16.4.4 Internal Reset

An internal reset clears the SIM counter and the COP counter.

#### 16.4.5 Reset Vector Fetch

A reset vector fetch occurs when the vector address appears on the data bus. A reset vector fetch clears the SIM counter.

#### 16.4.6 COPD (COP Disable)

The COPD signal reflects the state of the COP disable bit (COPD) in the configuration register (CONFIG). (See Section 5. Configuration Register (CONFIG).)

# 16.5 COP Control Register

The COP control register is located at address \$FFFF and overlaps the reset vector. Writing any value to \$FFFF clears the COP counter and starts a new timeout period. Reading location \$FFFF returns the low byte of the reset vector.

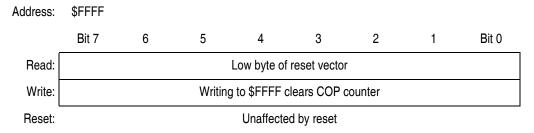

Figure 16-3. COP Control Register (COPCTL)

# 16.6 Interrupts

The COP does not generate CPU interrupt requests.

#### 16.7 Monitor Mode

The COP is disabled in monitor mode when  $V_{DD} + V_{HI}$  is present on the  $\overline{IRQ1}/V_{PP}$  pin or on the  $\overline{RST}$  pin.

#### 16.8 Wait Mode

The WAIT instruction puts the MCU in low-power-consumption standby mode.

The COP continues to operate during wait mode.

# 16.9 COP Module During Break Mode

The COP is disabled during a break interrupt when  $V_{DD} + V_{HI}$  is present on the  $\overline{RST}$  pin.

# Section 17. External Interrupt (IRQ)

## 17.1 Contents

17.2	Introduction	.339
17.3	Features	. 339

17.5	ĪRQ1/V <sub>PP</sub> Pin	.343
17.6	IRQ Module During Break Mode	. 344
17.7	IRQ Status and Control Register	.345

## 17.2 Introduction

This section describes the external interrupt module (IRQEPM, Version B), which supports external interrupt functions.

#### 17.3 Features

Features of the IRQ module include:

- A dedicated External Interrupt Pin (IRQ1/V<sub>PP</sub>)
- Hysteresis Buffers

# 17.4 Functional Description

A logic 0 applied to any of the external interrupt pins can latch a CPU interrupt request. Figure 17-1 shows the structure of the IRQ module.

Interrupt signals on the  $\overline{IRQ1}/V_{PP}$  pin are latched into the IRQ1 latch. An interrupt latch remains set until one of the following actions occurs:

- Vector fetch A vector fetch automatically generates an interrupt acknowledge signal that clears the latch that caused the vector fetch.
- Software clear Software can clear an interrupt latch by writing to the appropriate acknowledge bit in the interrupt status and control register (ISCR). Writing a logic 1 to the ACK1 bit clears the IRQ1 latch.
- Reset A reset automatically clears both interrupt latches.

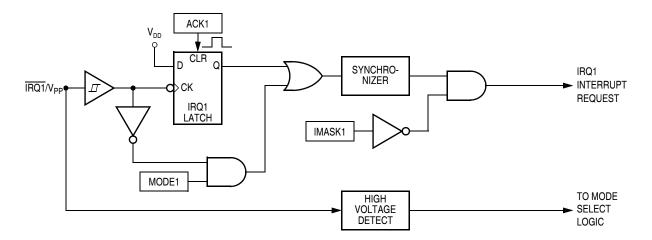

Figure 17-1. IRQ Module Block Diagram

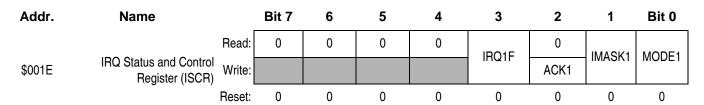

Figure 17-2. IRQ I/O Register Summary

**Technical Data** 

MC68HC708MP16 — Rev. 3.1

The external interrupt pins are falling-edge-triggered and are software-configurable to be both falling-edge and low-level-triggered. The MODE1 bit in the ISCR controls the triggering sensitivity of the IRQ1/V<sub>PP</sub> pin.

When the interrupt pin is edge-triggered only, the interrupt latch remains set until a vector fetch, software clear, or reset occurs.

When the interrupt pin is both falling-edge and low-level-triggered, the interrupt latch remains set until both of the following occur:

- Vector fetch, software clear, or reset
- Return of the interrupt pin to logic 1

The vector fetch or software clear can occur before or after the interrupt pin returns to logic 1. As long as the pin is low, the interrupt request remains pending.

When set, the IMASK1 bit in the ISCR mask all external interrupt requests. A latched interrupt request is not presented to the interrupt priority logic unless the IMASK bit is clear.

**NOTE:** 

The interrupt mask (I) in the condition code register (CCR) masks all interrupt requests, including external interrupt requests.

(See Figure 17-3.)

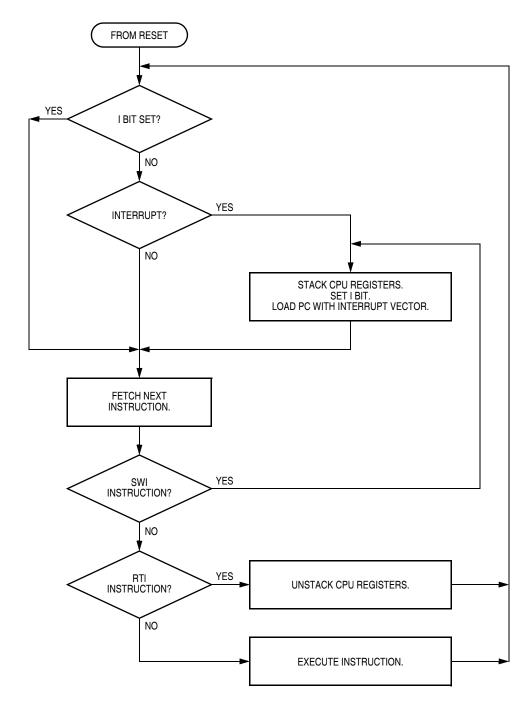

Figure 17-3. IRQ Interrupt Flowchart

# 17.5 IRQ1/V<sub>PP</sub> Pin

A logic 0 on the  $\overline{IRQ1}/V_{PP}$  pin can latch an interrupt request into the IRQ1 latch. A vector fetch, software clear, or reset clears the IRQ1 latch.

If the MODE1 bit is set, the IRQ1/V<sub>PP</sub> pin is both falling-edge-sensitive and low-level-sensitive. With MODE1 set, both of the following actions must occur to clear the IRQ1 latch:

- Vector fetch, software clear, or reset A vector fetch generates an interrupt acknowledge signal to clear the latch. Software can generate the interrupt acknowledge signal by writing a logic 1 to the ACK1 bit in the interrupt status and control register (ISCR). The ACK1 bit is useful in applications that poll the IRQ1/V<sub>PP</sub> pin and require software to clear the IRQ1 latch. Writing to the ACK1 bit can also prevent spurious interrupts due to noise. Setting ACK1 does not affect subsequent transitions on the IRQ1/V<sub>PP</sub> pin. A falling edge that occurs after writing to the ACK1 bit latches another interrupt request. If the IRQ1 mask bit, IMASK1, is clear, the CPU loads the program counter with the vector address at locations \$FFFA and \$FFFB.
- Return of the IRQ1/V<sub>PP</sub> pin to logic 1 As long as the IRQ1/V<sub>PP</sub> pin is at logic 0, the IRQ1 latch remains set.

The vector fetch or software clear and the return of the IRQ1/ $V_{PP}$  pin to logic 1 can occur in any order. The interrupt request remains pending as long as the  $\overline{IRQ1}/V_{PP}$  pin is at logic 0.

If the MODE1 bit is clear, the  $\overline{IRQ1}/V_{PP}$  pin is falling-edge-sensitive only. With MODE1 clear, a vector fetch or software clear immediately clears the IRQ1 latch.

Use the BIH or BIL instruction to read the logic level on the  $\overline{IRQ1}/V_{PP}$  pin.

**NOTE:** When using the level-sensitive interrupt trigger, avoid false interrupts by masking interrupt requests in the interrupt routine.

# 17.6 IRQ Module During Break Mode

The system integration module (SIM) controls whether the IRQ1 interrupt latch can be cleared during the break state. The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear the latches during the break state. (See 7.7.4 SIM Break Flag Control Register.)

To allow software to clear the IRQ1 latch during a break interrupt, write a logic 1 to the BCFE bit. If a latch is cleared during the break state, it remains cleared when the MCU exits the break state.

To protect the latches during the break state, write a logic 0 to the BCFE bit. With BCFE at logic 0 (its default state), writing to the ACK1 bit in the IRQ status and control register during the break state has no effect on the IRQ latches. (See 17.7 IRQ Status and Control Register.)

# 17.7 IRQ Status and Control Register

The IRQ status and control register (ISCR) has these functions:

- Clears the IRQ1 interrupt latch
- Masks IRQ1 interrupt requests
- Controls triggering sensitivity of the IRQ1/V<sub>PP</sub> interrupt pin

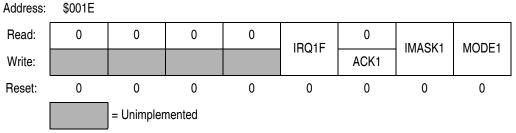

Figure 17-4. IRQ Status and Control Register (ISCR)

#### ACK1 — IRQ1 Interrupt Request Acknowledge Bit

Writing a logic 1 to this write-only bit clears the IRQ1 latch. ACK1 always reads as logic 0. Reset clears ACK1.

#### IMASK1 — IRQ1 Interrupt Mask Bit

Writing a logic 1 to this read/write bit disables IRQ1 interrupt requests. Reset clears IMASK1.

- 1 = IRQ1 interrupt requests disabled
- 0 = IRQ1 interrupt requests enabled

#### MODE1 — IRQ1 Edge/Level Select Bit

This read/write bit controls the triggering sensitivity of the IRQ1/V<sub>PP</sub> pin. Reset clears MODE1.

- $1 = \overline{IRQ1}/V_{PP}$  interrupt requests on falling edges and low levels
- $0 = \overline{IRQ1}/V_{PP}$  interrupt requests on falling edges only

#### IRQ1F — IRQ1 Flag

This read-only bit acts as a status flag, indicating an IRQ1 event occurred.

- 1 = External IRQ1 event occurred
- 0 = External IRQ1 event did not occur

MC68HC708MP16 — Rev. 3.1

18.5	LVI Status Register	350
18.6	LVI Interrupts	351
18.7	Wait Mode	351

#### 18.2 Introduction

This section describes the low-voltage inhibit module (LVI47, Version A), which monitors the voltage on the  $V_{DD}$  pin and can force a reset when the  $V_{DD}$  voltage falls to the LVI trip voltage.

#### 18.3 Features

Features of the LVI module include:

- Programmable LVI Reset
- Programmable Power Consumption
- Digital Filtering of V<sub>DD</sub> pin level

MC68HC708MP16 - Rev. 3.1

# 18.4 Functional Description

Figure 18-1 shows the structure of the LVI module. The LVI is enabled out of reset. The LVI module contains a bandgap reference circuit and comparator. The LVI power bit, LVIPWR, enables the LVI to monitor  $V_{DD}$  voltage. The LVI reset bit, LVIRST, enables the LVI module to generate a reset when  $V_{DD}$  falls below a voltage, LVI<sub>TRIPF</sub>, and remains at or below that level for nine or more consecutive CPU cycles. LVIPWR and LVIRST are in the configuration register (CONFIG). (See Section 5. Configuration Register (CONFIG).) Once an LVI reset occurs, the MCU remains in reset until  $V_{DD}$  rises above a voltage, LVI<sub>TRIPR</sub>.  $V_{DD}$  must be above LVI<sub>TRIPR</sub> for only one CPU cycle to bring the MCU out of reset. (See 7.4.2.5 Low-Voltage Inhibit (LVI) Reset.) The output of the comparator controls the state of the LVIOUT flag in the LVI status register (LVISR).

An LVI reset also drives the  $\overline{RST}$  pin low to provide low-voltage protection to external peripheral devices.

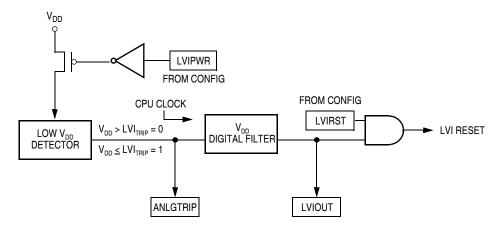

Figure 18-1. LVI Module Block Diagram

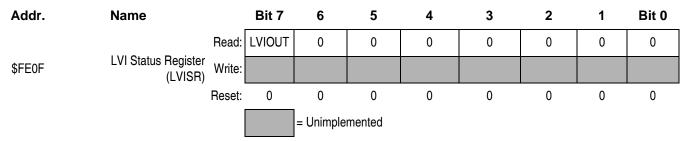

Figure 18-2. LVI I/O Register Summary

#### 18.4.1 Polled LVI Operation

In applications that can operate at  $V_{DD}$  levels below the LVI<sub>TRIPF</sub> level, software can monitor  $V_{DD}$  by polling the LVIOUT bit. In the configuration register, the LVIPWR bit must be at logic 0 to enable the LVI module, and the LVIRST bit must be at logic 1 to disable LVI resets.

#### **18.4.2 Forced Reset Operation**

In applications that require  $V_{DD}$  to remain above the LVI<sub>TRIPF</sub> level, enabling LVI resets allows the LVI module to reset the MCU when  $V_{DD}$  falls to the LVI<sub>TRIPF</sub> level and remains at or below that level for nine or more consecutive CPU cycles. In the configuration register, the LVIPWR and LVIRST bits must be at logic 0 to enable the LVI module and to enable LVI resets.

#### 18.4.3 False Reset Protection

The  $V_{DD}$  pin level is digitally filtered to reduce false resets due to power supply noise. In order for the LVI module to reset the MCU,  $V_{DD}$  must remain at or below the LVI<sub>TRIPF</sub> level for nine or more consecutive CPU cycles.  $V_{DD}$  must be above LVI<sub>TRIPR</sub> for only one CPU cycle to bring the MCU out of reset.

MC68HC708MP16 — Rev. 3.1

# 18.5 LVI Status Register

The LVI status register (LVISR) flags V<sub>DD</sub> voltages below the LVI<sub>TRIPF</sub> level.

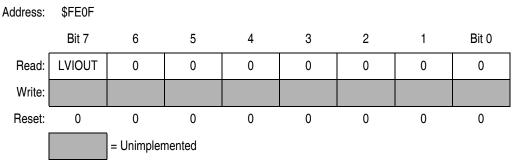

Figure 18-3. LVI Status Register (LVISR)

#### LVIOUT — LVI Output Bit

This read-only flag becomes set when the  $V_{DD}$  voltage falls below the  $LVI_{TRIPF}$  voltage for 32 to 40 CGMXCLK cycles. (See **Table 18-1**.) Reset clears the LVIOUT bit.

 $V_{DD}$ **LVIOUT** For Number of At Level: **CGMXCLK Cycles:** V<sub>DD</sub> > LVI<sub>TRIPR</sub> ANY 0  $V_{DD} < LVI_{TRIPF}$ < 32 CGMXCLK cycles 0 between 32 & 40 CGMXCLK  $V_{DD} < LVI_{TRIPF}$ 0 or 1 cycles > 40 CGMXCLK cycles 1 V<sub>DD</sub> < LVI<sub>TRIPF</sub>  $LVI_{TRIPF} < V_{DD} <$ ANY Previous Value LVITRIPR

Table 18-1. LVIOUT Bit Indication

# 18.6 LVI Interrupts

The LVI module does not generate interrupt requests.

## 18.7 Wait Mode

The WAIT instruction puts the MCU in low-power-consumption standby mode.

With the LVIPWR bit in the configuration register programmed to logic 0, the LVI module is active after a WAIT instruction.

With the LVIRST bit in the configuration register programmed to logic 0, the LVI module can generate a reset and bring the MCU out of wait mode.

# Low-Voltage Inhibit (LVI)

# Section 19. Analog-to-Digital Converter (ADC)

# 19.1 Contents

MC68HC708MP16 — Rev. 3.1

# **Analog-to-Digital Converter (ADC)**

#### 19.2 Introduction

This section describes the analog-to-digital convertor. The ADC is an 8-bit analog-to-digital convertor.

#### 19.3 Features

Features of the ADC module include:

- 10 channels with multiplexed input
- Linear successive approximation
- 8-bit resolution
- Single or continous conversion
- Conversion complete flag or conversion complete interrupt
- Selectable ADC Clock

## 19.4 Functional Description

Ten ADC channels are available for sampling external sources at pins PTC1/ATD9:PTC0/ATD8 and PTB7/ATD7:PTB0/ATD0. An analog multiplexer allows the single ADC converter to select one of the 10 ADC channels as ADC voltage IN (ADCVIN). ADCVIN is converted by the successive approximation register based counter. When the conversion is completed, the ADC places the result in the ADC data register and sets a flag or generates an interrupt. (See Figure 19-1.)

**NOTE:** 

DMA section and associated functions are only valid if the MCU has a DMA module.

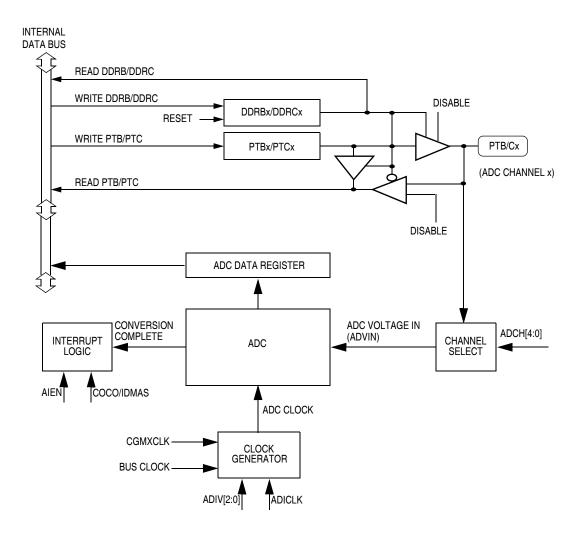

Figure 19-1. ADC Block Diagram

# **Analog-to-Digital Converter (ADC)**

#### 19.4.1 ADC Port I/O Pins

PTC1/ATD9:PTC0/ATD8 and PTB7/ATD7:PTB0/ATD0 are general-purpose I/O pins that are shared with the ADC channels.

The channel select bits define which ADC channel/port pin will be used as the input signal. The ADC overrides the port I/O logic by forcing that pin as input to the ADC. The remaining ADC channels/port pins are controlled by the port I/O logic and can be used as general-purpose I/O. Writes to the port register or DDR will not have any affect on the port pin that is selected by the ADC. Read of a port pin which is in use by the ADC will return a logic 0.

#### 19.4.2 Voltage Conversion

When the input voltage to the ADC equals  $V_{DDAD}$ , the ADC converts the signal to \$FF (full scale). If the input voltage equals  $V_{SSAD}$ , the ADC converts it to \$00. Input voltages between  $V_{DDAD}$  and  $V_{SSAD}$  are straight-line linear conversions. All other input voltages will result in \$FF if greater than  $V_{DDAD}$  and \$00 if less than  $V_{SSAD}$ .

**NOTE:** Input voltage should not exceed the analog supply voltages.

#### 19.4.3 Conversion Time

Conversion starts after a write to the ADSCR. Conversion time in terms of the number of bus cycles is a function of oscillator frequency, bus frequency, and ADIV prescaler bits. For example, with an oscillator frequency of 8 MHz, a bus frequency of 4 MHz, and an ADC clock frequency of 1 MHz, one conversion will take between 16 ADC and 17 ADC clock cycles or between 16 and 17  $\mu s$ . There will be 128 bus cycles between each conversion. Sample rate is approximately 30 kHz.

Conversion Time = 
$$\frac{16-17 \text{ ADC Cycles}}{\text{ADC Frequency}}$$

Number of Bus Cycles = Conversion Time x Bus Frequency

#### 19.4.4 Continous Conversion

In the continuous conversion mode, the ADC data register will be filled with new data after each conversion. Data from the previous conversion will be overwritten whether that data has been read or not. Conversions will continue until the ADCO bit is cleared. The COCO bit is set after the first conversion and will stay set for the next several conversions until the next write of the ADC status and control register or the next read of the ADC data register.

#### 19.4.5 Accuracy and Precision

The conversion process is monotonic and has no missing codes.

# 19.5 Interrupts

When the AIEN bit is set, the ADC module is capable of generating either CPU or DMA interrupt after each ADC conversion. A CPU interrupt is generated if the COCO/IDMAS bit is at logic 0. If COCO/IDMAS bit is set, a DMA interrupt is generated. The COCO/IDMAS bit is not used as a conversion complete flag when interrupts are enabled.

#### 19.6 Wait Mode

The WAIT instruction can put the MCU in low-power-consumption standby mode.

The ADC continues normal operation during wait mode. Any enabled CPU interrupt request from the ADC can bring the MCU out of wait mode. If the ADC is not required to bring the MCU out of wait mode, power down the ADC by setting ADCH[4:0] bits in the ADC status and Control Register before executing the WAIT instruction.

MC68HC708MP16 — Rev. 3.1

# Analog-to-Digital Converter (ADC)

# 19.7 I/O Signals

The ADC module has 10 I/O signals that are shared with port B and port C.

### 19.7.1 ADC Analog Power Pin (V<sub>DDAD</sub>)

The ADC analog portion uses  $V_{DDAD}$  as its power pin. Connect the  $V_{DDAD}$  pin to the same voltage potential as  $V_{DD}$ . External filtering may be necessary to ensure clean  $V_{DDAD}$  for good results.

**NOTE:** Route  $V_{DDAD}$  carefully for maximum noise immunity and place bypass capacitors as close as possible to the package.

## 19.7.2 ADC Analog Ground Pin (V<sub>SSAD</sub>)

The ADC analog portion uses  $V_{SSAD}$  as its ground pin. Connect the  $V_{SSAD}$  pin to the same voltage potential as  $V_{SS}$ .

## 19.7.3 ADC Voltage Reference Pin (V<sub>DDAREF</sub>)

 $V_{DDAREF}$  is the power supply for setting the reference voltage  $V_{REFH}$ . Connect the  $V_{DDAREF}$  pin to the same voltage potential as  $V_{DDA}$ .

# 19.7.4 ADC Voltage Decoupling Capacitor Pin (V<sub>ADCAP</sub>)

 $V_{ADCAP}$  is one of two reference supplies and is generated from  $V_{DDAREF}$  with a value ( $V_{DDAREF}$ )/2. Place a bypass capacitor on this pin to decouple noise.  $V_{ADCAP}$  pin can also be used to drive an upper reference value of ( $V_{DDAREF}$ )/2 with an external voltage reference.

## 19.7.5 ADC Voltage Reference Low Pin (V<sub>REFL</sub>)

 $V_{REFL}$  is the lower reference supply for the ADC. Connect the  $V_{REFL}$  pin to the same voltage potential as  $V_{SSAD}$ .

## 19.7.6 ADC Voltage In (ADVIN)

ADVIN is the input voltage signal from one of the 10 ADC channels to the ADC module.

# 19.8 I/O Registers

The following I/O registers control and monitor operation of the ADC:

- ADC status and control register (ADSCR)
- ADC data register (ADR)
- ADC clock register (ADCLK)

#### 19.8.1 ADC Status and Control Register

These paragraphs describe the function of the ADC status and control register (ADSCR).

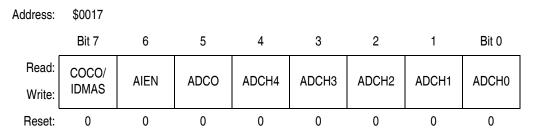

Figure 19-2. ADC Status and Control Register (ADSCR)

COCO/IDMAS — Conversions Complete / Interrupt DMA Select

When AIEN bit is a logic 0, the COCO/IDMAS is a read-only bit which is set each time a conversion is completed except in the continous conversion mode where it is set after the first conversion. This bit is cleared whenever the ADC status and control register is written or whenever the ADC data register is read.

If AIEN bit is a logic 1, the COCO/IDMAS is a read/write bit which selects either CPU or DMA to service the ADC interrupt request. Reset clears this bit.

- 1 = Conversion completed (AIEN = 0)/DMA interrrupt (AIEN = 1)
- 0 = Conversion not completed (AIEN = 0)/CPU interrupt (AIEN = 1)

#### AIEN — ADC Interrupt Enable

When this bit is set, an interrupt is generated at the end of an ADC conversion. The interrupt signal is cleared when the data register is read or the status/control register is written. Reset clears the AIEN bit.

- 1 = ADC interrupt enabled
- 0 = ADC interrupt disabled

#### ADCO — ADC Continuous Conversion

When set, the ADC will convert samples continuously and update the ADR register at the end of each conversion. Only one conversion is allowed when this bit is cleared. Reset clears the ADCO bit.

- 1 = Continuous ADC conversion
- 0 = One ADC conversion

#### ADCH[4:10 — ADC Channel Select Bits

ADCH4, ADCH3, ADCH2, ADCH1, and ADCH0 form a 5-bit field which is used to select one of 14 ADC channels. The 14 channels are detailed in **Table 19-1**. Take care to prevent switching noise from corrupting the analog signal when simultaneously using a port pin as both an analog and digital input. (See **Table 19-1**.)

The ADC subsystem is turned off when the channel select bits are all set to one. This feature allows for reduced power consumption for the MCU when the ADC is not used.

**NOTE:** Recovery from the disabled state requires one conversion cycle to stabilize.

The voltage levels supplied from internal reference nodes as specified in **Table 19-1** are used to verify the operation of the ADC converter both in production test and for user applications.

**Table 19-1. Mux Channel Select** 

ADCH4	ADCH3	ADCH2	ADCH1	ADCH0	Input Select
0	0	0	0	0	PTB0/ATD0
0	0	0	0	1	PTB1/ATD1
0	0	0	1	0	PTB2/ATD2

1	1	1	1	1	[ADC power off]

#### Notes:

- 1. If any unused channels are selected, the resulting ADC conversion will be unknown.
- 2. Used for factory testing.

#### 19.8.2 ADC Data Register

One 8-bit result register is provided. This register is updated each time an ADC conversion completes.

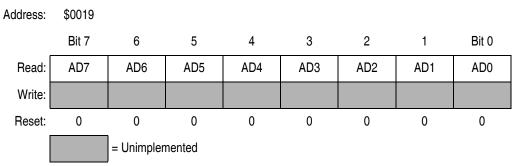

Figure 19-3. ADC Data Register (ADR)

#### 19.8.3 ADC Clock Register

This register selects the clock frequency for the ADC.

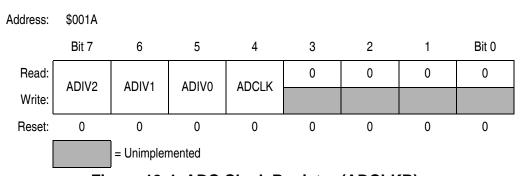

Figure 19-4. ADC Clock Register (ADCLKR)

ADIV2:ADIV0 — ADC Clock Prescaler Bits

ADIV2, ADIV1, and ADIV0 form a 3-bit field which selects the divide ratio used by the ADC to generate the internal ADC clock.

**Table 19-2** shows the available clock configurations. The ADC clock should be set to 1 MHz.

MC68HC708MP16 - Rev. 3.1

Table 19-2. ADC Clock Divide Ratio

ADIV2	ADIV1	ADIV0	ADC Clock Rate
0	0	0	ADC input clock /1
0	0	1	ADC input clock /2
0	1	0	ADC input clock /4
0	1	1	ADC input clock /8
1	Х	Х	ADC input clock /16

X = don't care

#### ADICLK — ADC Input Clock Select

ADICLK selects either bus clock or CGMXCLK as the input clock source to generate the internal ADC clock. Reset selects CGMXCLK as the ADC clock source.

If the external clock (CGMXCLK) is equal or greater than 1 MHz, CGMXCLK can be used as the clock source for the ADC. If CGMXCLK is less than 1 MHz, use the PLL-generated bus clock as the clock source. As long as the internal ADC clock is at 1 MHz, correct operation can be guaranteed. (See 21.11 Analog-to-Digital Converter (ADC) Characteristics.)

1 = Internal bus clock

0 = External clock (CGMXCLK)

1 MHz = 
$$\frac{CGMXCLK \text{ or Bus Frequency}}{ADIV[2:0]}$$

# Section 20. Power-On Reset (POR)

#### 20.1 Contents

20.2	Introduction	365
20.3	Functional Description	365

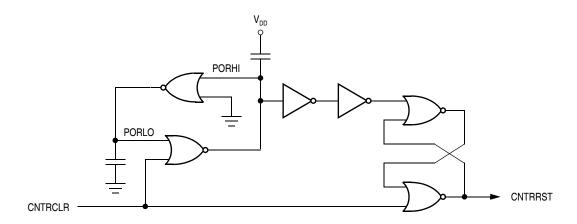

#### 20.2 Introduction

This section describes the power-on reset (POR) module (Version B).

# 20.3 Functional Description

The POR module provides a known, stable signal to the MCU at power-on. This signal tracks  $V_{DD}$  until the MCU generates a feedback signal to indicate that it is properly initialized. At this time, the POR drives its output low. The POR is not a brown-out detector, low-voltage detector, or glitch detector.  $V_{DD}$  at the POR must go completely to zero to reset the MCU. To detect power-loss conditions, use a low voltage inhibit module (LVI) or other suitable circuit. Inputs to the POR\_B00 are SIMINIT and SECZDET from the SIM and EPROM security circuits, respectively.

MC68HC708MP16 — Rev. 3.1

#### NOTES:

- 1. PORHI goes high at power-up and is cleared when the SIM sets CNTRCLR.
- 2. Signal names are not necessarily accurate. This diagram is for logical illustration only and may not represent actual circuitry.

Figure 20-1. POR Block Diagram

### 21.2 Introduction

This section contains electrical and timing specifications. These values are design targets and have not yet been fully characterized.

### 21.3 Absolute Maximum Ratings

Maximum ratings are the extreme limits to which the MCU can be exposed without permanently damaging it.

NOTE:

This device is not guaranteed to operate properly at the maximum ratings. Refer to **21.6 DC Electrical Characteristics** for guaranteed operating conditions.

Table 21-1. Absolute Maximum Ratings<sup>(1)</sup>

Characteristic	Symbol	Value	Unit
Supply Voltage	$V_{DD}$	-0.3 to +6.0	V
Input Voltage	V <sub>IN</sub>	$V_{SS}$ –0.3 to $V_{DD}$ +0.3	V
Programming Voltage	$V_{PP}$	V <sub>SS</sub> -0.3 to 14.0	V
Maximum Current Per Pin Excluding V <sub>DD</sub> and V <sub>SS</sub>	I	l ± 25	
Storage Temperature	T <sub>STG</sub>	-55 to +150	°C
Maximum Current Out of V <sub>SS</sub>	I <sub>MVSS</sub>	100	mA
Maximum Current Into V <sub>DD</sub>	I <sub>MVDD</sub>	100	mA

#### Note:

#### NOTE:

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. For proper operation, it is recommended that  $V_{IN}$  and  $V_{OUT}$  be constrained to the range  $V_{SS} \leq (V_{IN} \text{ or } V_{OUT}) \leq V_{DD}$ . Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either  $V_{SS}$  or  $V_{DD}$ .)

<sup>1.</sup> Voltages referenced to V<sub>SS</sub>.

### 21.4 Functional Operating Range

**Table 21-2. Operating Range** 

Characteristic	Symbol	Value	Unit
Operating Temperature Range (see Note) MC68HC708MP16CFU MC68HC708MP16VFU	T <sub>A</sub>	-40 to 85 -40 to 105	°C
Operating Voltage Range	$V_{DD}$	5.0 ± 10%	V

#### Note:

See Freescale representative for temperature availability.

C = Extended temperature range (-40 to +85 °C)

V = Automotive temperature range (-40 to +105 °C)

### 21.5 Thermal Characteristics

**Table 21-3. Thermal Characteristics** 

Characteristic	Symbol	Value	Unit
Thermal Resistance, QFP (64 Pin)	$\theta_{\sf JA}$	76	°C/W
I/O Pin Power Dissipation	P <sub>I/O</sub>	User Determined	W
Power Dissipation <sup>(1)</sup>	P <sub>D</sub>	$P_D = (I_{DD} \times V_{DD}) + P_{I/O} = K/(T_J + 273 \text{ °C})$	W
Constant <sup>(2)</sup>	К	$P_{D} x (T_{A} + 273 \text{ °C}) + P_{D}^{2} x \theta_{JA}$	W/°C
Average Junction Temperature	TJ	$T_A + (P_D \times \theta_{JA})$	°C
Maximum Junction Temperature	$T_JM$	125	°C

#### Notes:

- 1. Power dissipation is a function of temperature.
- 2. K is a constant unique to the device. K can be determined for a known  $T_A$  and measured  $P_{D.}$  With this value of K,  $P_D$  and  $T_J$  can be determined for any value of  $T_A$ .

POR Rise Time Ramp Rate <sup>(8)</sup>	R <sub>POR</sub>	0.035	_	_	V/m s

#### Notes:

- 1.  $V_{DD} = 5.0 \text{ Vdc} \pm 10\%$ ,  $V_{SS} = 0 \text{ Vdc}$ ,  $T_A = T_L$  to  $T_H$ , unless otherwise noted.
- 2. Typical values reflect average measurements at midpoint of voltage range, 25 °C only.
- 3. Run (operating) I<sub>DD</sub> measured using external square wave clock source (f<sub>osc</sub> = 8.2 MHz). All inputs 0.2 V from rail. No dc loads. Less than 100 pF on all outputs. C<sub>L</sub> = 20 pF on OSC2. All ports configured as inputs. OSC2 capacitance linearly affects run I<sub>DD</sub>. Measured with all modules enabled.
- 4. Wait I<sub>DD</sub> measured using external square wave clock source (f<sub>osc</sub> = 8.2 MHz); all inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs. C<sub>L</sub> = 20 pF on OSC2; all ports configured as inputs; OSC2 capacitance linearly affects wait I<sub>DD</sub>; measured with PLL, and LVI enabled.
- 5. Quiescent I<sub>DD</sub> measured with PLL and LVI disengaged, OCS1 grounded, no port pins sourcing current. Measured through combination of V<sub>DD</sub>, V<sub>DDAD</sub>, and V<sub>DDA</sub>.
- 6. Maximum is highest voltage that POR is guaranteed.
- 7. Maximum is highest voltage that POR is possible.
- 8. If minimum  $V_{DD}$  is not reached before the internal POR reset is released,  $\overline{RST}$  must be driven low externally until minimum  $V_{DD}$  is reached.

## 21.7 Control Timing

Table 21-5. Control Timing  $(V_{DD}$  = 5.0 Vdc  $\pm$  10%)<sup>(1)</sup>

Characteristic	Symbol	Min	Max	Unit
Frequency of Operation <sup>(2)</sup> Crystal Option External Clock Option <sup>(3)</sup>	f <sub>OSC</sub>	1 M dc <sup>(4)</sup>	8 M 32.8 M	Hz
Internal Operating Frequency	f <sub>OP</sub>	_	8.2	MHz
RESET Input Pulse Width Low <sup>(5)</sup>	t <sub>IRL</sub>	50	_	ns

#### Notes:

- 1.  $V_{SS} = 0$  Vdc; timing shown with respect to 20%  $V_{DD}$  and 70%  $V_{DD}$ , unless otherwise noted.
- 2. See Table 21-8 and Table 21-9 for more information.
- 3. No more than 10% duty cycle deviation from 50%.
- 4. Some modules may require a minimum frequency greater than dc for proper operation; see appropriate table for this information.
- 5. Minimum pulse width reset is guaranteed to be recognized. It is possible for a smaller pulse width to cause a reset.

## 21.8 Serial Peripheral Interface Characteristics

Table 21-6. Serial Peripheral Interface (SPI) Timing ( $V_{DD}$  = 5.0 Vdc  $\pm$  10%) <sup>(1)</sup>

Diagram Number <sup>(2)</sup>	Characteristic	Symbol	Min	Max	Unit
	Operating Frequency Master Slave	f <sub>OP(M)</sub> f <sub>OP(S)</sub>	f <sub>OP</sub> /128 DC	f <sub>OP</sub> /2 f <sub>OP</sub>	MHz
1	Cycle Time Master Slave	t <sub>CYC(M)</sub>	2	128 —	t <sub>CYC</sub>
2	Enable Lead Time	t <sub>LEAD(S)</sub>	15	_	ns
3	Enable Lag Time	t <sub>LAG(S)</sub>	15	_	ns
4	Clock (SCK) High Time Master Slave	tsckh(M) tsckh(s)	100 50		ns
5	Clock (SCK) Low Time Master Slave	t <sub>SCKL(M)</sub>	100 50		ns
6	Data Setup Time (Inputs)  Master Slave	t <sub>SU(M)</sub>	45 5		ns
7	Data Hold Time (Inputs) Master Slave	t <sub>H(M)</sub> t <sub>H(S)</sub>	0 15	_	ns
8	Access Time, Slave <sup>(3)</sup> CPHA = 0 CHPA = 1	t <sub>A(CP0)</sub>	0	40 20	ns
9	Disable Time, Slave <sup>(4)</sup>	t <sub>DIS(S)</sub>	_	25	ns
10	Data Valid Time (After Enable Edge) Master Slave <sup>(5)</sup>	t <sub>V(M)</sub>	_ _	10 40	ns

#### Notes:

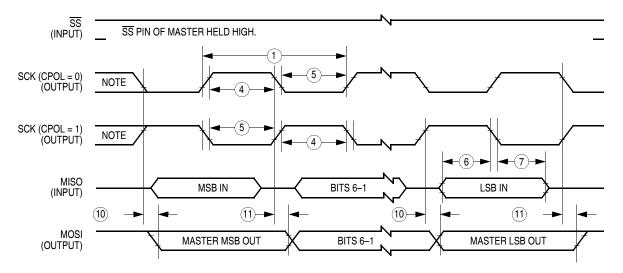

<sup>1.</sup> All timing is shown with respect to 20%  $V_{DD}$  and 70%  $V_{DD}$ , unless otherwise noted; assumes 100 pF load on all SPI pins.

<sup>2.</sup> Numbers refer to dimensions in Figure 21-1 and Figure 21-2.

<sup>3.</sup> Time to data active from high-impedance state.

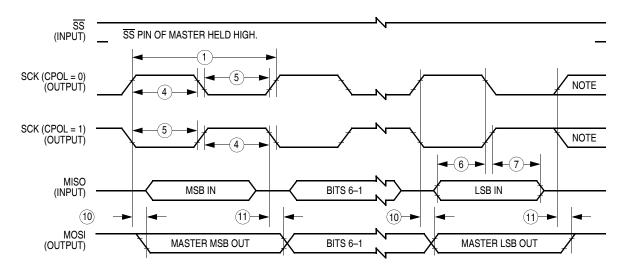

<sup>4.</sup> Hold time to high-impedance state.

<sup>5.</sup> With 100 pF on all SPI pins.

NOTE: This first clock edge is generated internally, but is not seen at the SCK pin.

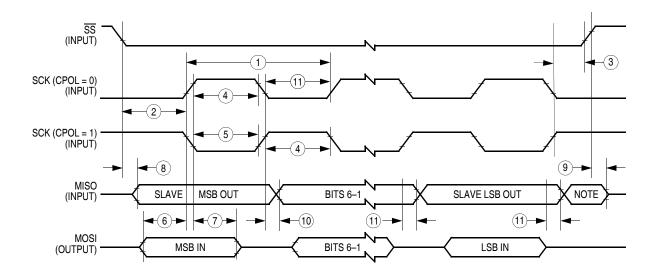

#### a) SPI Master Timing (CPHA = 0)

NOTE: This last clock edge is generated internally, but is not seen at the SCK pin.

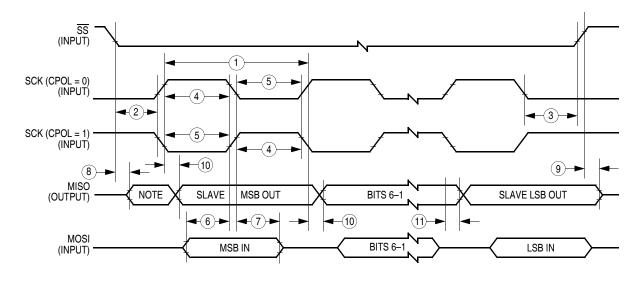

#### b) SPI Master Timing (CPHA = 1)

Figure 21-1. SPI Master Timing

NOTE: Not defined but normally MSB of character just received.

#### a) SPI Slave Timing (CPHA = 0)

NOTE: Not defined but normally LSB of character previously transmitted. \\

b) SPI Slave Timing (CPHA = 1)

22.2	Introduction	379
22.3	Plastic Quad Flat Pack (QFP)	380

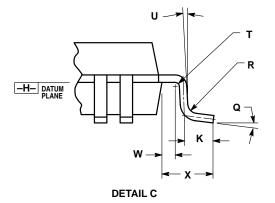

#### 22.2 Introduction

This section gives the dimensions for the 64-lead plastic quad flat pack (QFP).

MC68HC708MP16 — Rev. 3.1

### 22.3 Plastic Quad Flat Pack (QFP)

- NOTES:
  1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
  2. CONTROLLING DIMENSION: MILLIMETER.
- 2. CONTROLLING DIMENSION: MILLIMETER.
  3. DATUM PLANE -H- IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.

  4. DATUMS -A-, -B- AND -D- TO BE DETERMINED AT DATUM PLANE -H-.

  5. DIMENSIONS S AND V TO BE DETERMINED AT SEATING PLANE -C-.

- SIMINENSIONS AND VIO BE DETERMINED AT SEATING PLANE –C.
   DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.25 (0.010) PER SIDE. DIMENSIONS A AND B DO INCLUDE MOLD MISMATCH AND ARE
- DETERMINED AT DATUM PLANE—H—.

  7. DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION: ALLOWABLE DANIBAR PROTRUSION SHALL BE 0.08 (0.003) PER SIDE. TOTAL IN EXCESS OF THE D DIMENSION AT MAXIMUM MATERIAL CONDITION. DAMBAR CANNOT BE LOCATED ON THE LOWER RADIUS OR THE FOOT.

# Ordering Information

# Glossary

- **A** See accumulator (A).
- **accumulator (A)** An 8-bit general-purpose register in the CPU08. The CPU08 uses the accumulator to hold operands and results of arithmetic and logic operations.
- **acquisition mode** A mode of PLL operation during startup before the PLL locks on a frequency. Also see tracking mode.
- address bus The set of wires that the CPU or DMA uses to read and write memory locations.
- addressing mode The way that the CPU determines the operand address for an instruction. The M68HC08 CPU has 16 addressing modes.
- **ALU** See arithmetic logic unit (ALU).
- arithmetic logic unit (ALU) The portion of the CPU that contains the logic circuitry to perform arithmetic, logic, and manipulation operations on operands.
- **asynchronous** Refers to logic circuits and operations that are not synchronized by a common reference signal.
- **baud rate** The total number of bits transmitted per unit of time.
- **BCD** See binary-coded decimal (BCD).
- binary Relating to the base 2 number system.
- binary number system The base 2 number system, having two digits, 0 and 1. Binary arithmetic is convenient in digital circuit design because digital circuits have two permissible voltage levels, low and high. The binary digits 0 and 1 can be interpreted to correspond to the two digital voltage levels.

binary-coded decimal (BCD) — A notation that uses 4-bit binary numbers to represent the 10 decimal digits and that retains the same positional structure of a decimal number. For example,

234 (decimal) = 0010 0011 0100 (BCD)

bit — A binary digit. A bit has a value of either logic 0 or logic 1.

**branch instruction** — An instruction that causes the CPU to continue processing at a memory location other than the next sequential address.

**break module** — A module in the M68HC08 Family. The break module allows software to halt program execution at a programmable point in order to enter a background routine.

breakpoint — A number written into the break address registers of the break module. When a number appears on the internal address bus that is the same as the number in the break address registers, the CPU executes the software interrupt instruction (SWI).

**break interrupt** — A software interrupt caused by the appearance on the internal address bus of the same value that is written in the break address registers.

**bus** — A set of wires that transfers logic signals.

**bus clocks** — There are two bus clocks, IT12 and IT23. These clocks are generated by the CGM and distributed throughout the MCU by the SIM. The frequency of the bus clocks, or operating frequency, is f<sub>OP</sub>. While the frequency of these two clocks is the same, the phase is different.

**byte** — A set of eight bits.

C — The carry/borrow bit in the condition code register. The CPU08 sets the carry/borrow bit when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some logical operations and data manipulation instructions also clear or set the carry/borrow bit (as in bit test and branch instructions and shifts and rotates).

**CCR** — See condition code register.

**Technical Data** 

- **central processor unit (CPU)** The primary functioning unit of any computer system. The CPU controls the execution of instructions.
- **CGM** See clock generator module (CGM).
- **clear** To change a bit from logic 1 to logic 0; the opposite of set.
- clock A square wave signal used to synchronize events in a computer.
- clock generator module (CGM) A module in the M68HC08 Family. The CGM generates a base clock signal from which the system clocks are derived. The CGM may include a crystal oscillator circuit and/or phase-locked loop (PLL) circuit.
- comparator A device that compares the magnitude of two inputs. A digital comparator defines the equality or relative differences between two binary numbers.
- **computer operating properly module (COP)** A counter module in the M68HC08 Family that resets the MCU if allowed to overflow.
- **condition code register (CCR)** An 8-bit register in the CPU08 that contains the interrupt mask bit and five bits that indicate the results of the instruction just executed.
- **control bit** One bit of a register manipulated by software to control the operation of the module.
- control unit One of two major units of the CPU. The control unit contains logic functions that synchronize the machine and direct various operations. The control unit decodes instructions and generates the internal control signals that perform the requested operations. The outputs of the control unit drive the execution unit, which contains the arithmetic logic unit (ALU), CPU registers, and bus interface.
- **COP** See computer operating properly module (COP).
- **counter clock** The input clock to the TIM counter. This clock is an output of the prescaler sub-module. The frequency of the counter clock is f<sub>TCNT</sub>, and the period is t<sub>TCNT</sub>.
- **CPU** See central processor unit (CPU).

- **CPU08** The central processor unit of the M68HC08 Family.
- **CPU cycles** A CPU clock cycle is one period of the internal bus-rate clock, f<sub>OP</sub>, normally derived by dividing a crystal oscillator source by two or more so the high and low times will be equal. The length of time required to execute an instruction is measured in CPU clock cycles.
- CPU registers Memory locations that are wired directly into the CPU logic instead of being part of the addressable memory map. The CPU always has direct access to the information in these registers. The CPU registers in an M68HC08 are:
  - A (8-bit accumulator)
  - H:X (16-bit index register)
  - SP (16-bit stack pointer)
  - PC (16-bit program counter)
  - CCR (condition code register containing the V, H, I, N, Z, and C bits)
- **CSIC** customer-specified integrated circuit
- **cycle time** The period of the operating frequency:  $t_{CYC} = 1/f_{OP}$ .
- **decimal number system** Base 10 numbering system that uses the digits zero through nine.
- direct memory access module (DMA) A M68HC08 Family module that can perform data transfers between any two CPU-addressable locations without CPU intervention. For transmitting or receiving blocks of data to or from peripherals, DMA transfers are faster and more code-efficient than CPU interrupts.
- **DMA** See direct memory access module (DMA).
- **DMA service request** A signal from a peripheral to the DMA module that enables the DMA module to transfer data.
- **duty cycle** A ratio of the amount of time the signal is on versus the time it is off. Duty cycle is usually represented by a percentage.

**Technical Data** 

- **EEPROM** Electrically erasable, programmable, read-only memory. A non-volatile type of memory that can be electrically reprogrammed.
- **EPROM** Erasable, programmable, read-only memory. A non-volatile type of memory that can be erased by exposure to an ultraviolet light source and then reprogrammed.
- **exception** An event such as an interrupt or a reset that stops the sequential execution of the instructions in the main program.
- external interrupt module (IRQ) A module in the M68HC08 Family with both dedicated external interrupt pins and port pins that can be enabled as interrupt pins.
- **fetch** To copy data from a memory location into the accumulator.
- **firmware** Instructions and data programmed into non-volatile memory.
- **free-running counter** A device that counts from zero to a predetermined number, then rolls over to zero and begins counting again.
- **full-duplex transmission** Communication on a channel in which data can be sent and received simultaneously.
- **H** The upper byte of the 16-bit index register (H:X) in the CPU08.
- H The half-carry bit in the condition code register of the CPU08. This bit indicates a carry from the low-order four bits of the accumulator value to the high-order four bits. The half-carry bit is required for binary-coded decimal arithmetic operations. The decimal adjust accumulator (DAA) instruction uses the state of the H and C bits to determine the appropriate correction factor.
- **hexadecimal** Base 16 numbering system that uses the digits 0 through 9 and the letters A through F.
- **high byte** The most significant eight bits of a word.
- **illegal address** An address not within the memory map
- **illegal opcode** A non-existent opcode.

- I The interrupt mask bit in the condition code register of the CPU08.
  When I is set, all interrupts are disabled.
- index register (H:X) A 16-bit register in the CPU08. The upper byte of H:X is called H. The lower byte is called X. In the indexed addressing modes, the CPU uses the contents of H:X to determine the effective address of the operand. H:X can also serve as a temporary data storage location.
- input/output (I/O) Input/output interfaces between a computer system and the external world. A CPU reads an input to sense the level of an external signal and writes to an output to change the level on an external signal.
- instructions Operations that a CPU can perform. Instructions are expressed by programmers as assembly language mnemonics. A CPU interprets an opcode and its associated operand(s) and instruction.
- interrupt A temporary break in the sequential execution of a program to respond to signals from peripheral devices by executing a subroutine.
- interrupt request A signal from a peripheral to the CPU intended to cause the CPU to execute a subroutine.
- I/O See input/output (I/0).
- **IRQ** See external interrupt module (IRQ).
- **jitter** Short-term signal instability.
- **latch** A circuit that retains the voltage level (logic 1 or logic 0) written to it for as long as power is applied to the circuit.
- **latency** The time lag between instruction completion and data movement.
- **least significant bit (LSB)** The rightmost digit of a binary number.
- **logic 1** A voltage level approximately equal to the input power voltage (V<sub>DD</sub>).

Technical Data

**logic 0** — A voltage level approximately equal to the ground voltage (V<sub>SS</sub>).

**low byte** — The least significant eight bits of a word.

**low voltage inhibit module (LVI)** — A module in the M68HC08 Family that monitors power supply voltage.

**LVI** — See low voltage inhibit module (LVI).

M68HC08 — A Freescale family of 8-bit MCUs.

**mark/space** — The logic 1/logic 0 convention used in formatting data in serial communication.

mask — 1. A logic circuit that forces a bit or group of bits to a desired state. 2. A photomask used in integrated circuit fabrication to transfer an image onto silicon.

**mask option** — An optional microcontroller feature that the customer chooses to enable or disable.

mask option register (MOR) — An EPROM location containing bits that enable or disable certain MCU features.

**MCU** — Microcontroller unit. See microcontroller.

memory location — Each M68HC08 memory location holds one byte of data and has a unique address. To store information in a memory location, the CPU places the address of the location on the address bus, the data information on the data bus, and asserts the write signal. To read information from a memory location, the CPU places the address of the location on the address bus and asserts the read signal. In response to the read signal, the selected memory location places its data onto the data bus.

**memory map** — A pictorial representation of all memory locations in a computer system.

microcontroller — Microcontroller unit (MCU). A complete computer system, including a CPU, memory, a clock oscillator, and input/output (I/O) on a single integrated circuit.

- **modulo counter** A counter that can be programmed to count to any number from zero to its maximum possible modulus.
- **monitor ROM** A section of ROM that can execute commands from a host computer for testing purposes.
- **MOR** See mask option register (MOR).
- most significant bit (MSB) The leftmost digit of a binary number.
- **multiplexer** A device that can select one of a number of inputs and pass the logic level of that input on to the output.
- N The negative bit in the condition code register of the CPU08. The CPU sets the negative bit when an arithmetic operation, logical operation, or data manipulation produces a negative result.
- **nibble** A set of four bits (half of a byte).
- **object code** The output from an assembler or compiler that is itself executable machine code, or is suitable for processing to produce executable machine code.
- **opcode** A binary code that instructs the CPU to perform an operation.
- open-drain An output that has no pullup transistor. An external pullup device can be connected to the power supply to provide the logic 1 output voltage.
- operand Data on which an operation is performed. Usually a statement consists of an operator and an operand. For example, the operator may be an add instruction, and the operand may be the quantity to be added.
- **oscillator** A circuit that produces a constant frequency square wave that is used by the computer as a timing and sequencing reference.
- **OTPROM** One-time programmable read-only memory. A non-volatile type of memory that cannot be reprogrammed.
- overflow A quantity that is too large to be contained in one byte or one word.
- **page zero** The first 256 bytes of memory (addresses \$0000–\$00FF).

**Technical Data** 

- parity An error-checking scheme that counts the number of logic 1s in each byte transmitted. In a system that uses odd parity, every byte is expected to have an odd number of logic 1s. In an even parity system, every byte should have an even number of logic 1s. In the transmitter, a parity generator appends an extra bit to each byte to make the number of logic 1s odd for odd parity or even for even parity. A parity checker in the receiver counts the number of logic 1s in each byte. The parity checker generates an error signal if it finds a byte with an incorrect number of logic 1s.
- **PC** See program counter (PC).
- peripheral A circuit not under direct CPU control.
- **phase-locked loop (PLL)** An oscillator circuit in which the frequency of the oscillator is synchronized to a reference signal.
- **PLL** See phase-locked loop (PLL).
- **pointer** Pointer register. An index register is sometimes called a pointer register because its contents are used in the calculation of the address of an operand, and therefore points to the operand.
- **polarity** The two opposite logic levels, logic 1 and logic 0, which correspond to two different voltage levels, V<sub>DD</sub> and V<sub>SS</sub>.
- **polling** Periodically reading a status bit to monitor the condition of a peripheral device.
- **port** A set of wires for communicating with off-chip devices.
- **prescaler** A circuit that generates an output signal related to the input signal by a fractional scale factor such as 1/2, 1/8, 1/10, etc.
- **program** A set of computer instructions that causes a computer to perform a desired operation or operations.
- program counter (PC) A 16-bit register in the CPU08. The PC register holds the address of the next instruction or operand that the CPU will use.
- **pull** An instruction that copies into the accumulator the contents of a stack RAM location. The stack RAM address is in the stack pointer.

- **pullup** A transistor in the output of a logic gate that connects the output to the logic 1 voltage of the power supply.
- **pulse-width** The amount of time a signal is on as opposed to being in its off state.
- **pulse-width modulation (PWM)** Controlled variation (modulation) of the pulse width of a signal with a constant frequency.
- **push** An instruction that copies the contents of the accumulator to the stack RAM. The stack RAM address is in the stack pointer.
- **PWM period** The time required for one complete cycle of a PWM waveform.
- RAM Random access memory. All RAM locations can be read or written by the CPU. The contents of a RAM memory location remain valid until the CPU writes a different value or until power is turned off.
- RC circuit A circuit consisting of capacitors and resistors having a defined time constant.
- **read** To copy the contents of a memory location to the accumulator.
- **register** A circuit that stores a group of bits.
- **reserved memory location** A memory location that is used only in special factory-test modes. Writing to a reserved location has no effect. Reading a reserved location returns an unpredictable value.
- **reset** To force a device to a known condition.
- **ROM** Read-only memory. A type of memory that can be read but cannot be changed (written). The contents of ROM must be specified before manufacturing the MCU.
- **SCI** See serial communication interface module (SCI).
- **serial** Pertaining to sequential transmission over a single line.
- **serial communication interface module (SCI)** A module in the M68HC08 Family that supports asynchronous communication.
- serial peripheral interface module (SPI) A module in the M68HC08 Family that supports synchronous communication.

**Technical Data** 

- **set** To change a bit from logic 0 to logic 1; opposite of clear.
- shift register A chain of circuits that can retain the logic levels (logic 1 or logic 0) written to them and that can shift the logic levels to the right or left through adjacent circuits in the chain.
- signed A binary number notation that accommodates both positive and negative numbers. The most significant bit is used to indicate whether the number is positive or negative, normally logic 0 for positive and logic 1 for negative. The other seven bits indicate the magnitude of the number.
- **SIM** See system integration module (SIM).
- software Instructions and data that control the operation of a microcontroller.
- **software interrupt (SWI)** An instruction that causes an interrupt and its associated vector fetch.
- **SPI** See serial peripheral interface module (SPI).
- **stack** A portion of RAM reserved for storage of CPU register contents and subroutine return addresses.
- **stack pointer (SP)** A 16-bit register in the CPU08 containing the address of the next available storage location on the stack.
- **start bit** A bit that signals the beginning of an asynchronous serial transmission.
- **status bit** A register bit that indicates the condition of a device.
- **stop bit** A bit that signals the end of an asynchronous serial transmission.
- subroutine A sequence of instructions to be used more than once in the course of a program. The last instruction in a subroutine is a return from subroutine (RTS) instruction. At each place in the main program where the subroutine instructions are needed, a jump or branch to subroutine (JSR or BSR) instruction is used to call the subroutine. The CPU leaves the flow of the main program to execute the instructions in the subroutine. When the RTS instruction is executed, the CPU returns to the main program where it left off.

- **synchronous** Refers to logic circuits and operations that are synchronized by a common reference signal.
- system integration module (SIM) One of a number of modules that handle a variety of control functions in the modular M68HC08 Family. The SIM controls mode of operation, resets and interrupts, and system clock distribution.
- **TIM** See timer interface module (TIM).
- **timer interface module (TIM)** A module used to relate events in a system to a point in time.
- **timer** A module used to relate events in a system to a point in time.
- **toggle** To change the state of an output from a logic 0 to a logic 1 or from a logic 1 to a logic 0.
- **tracking mode** Mode of low-jitter PLL operation during which the PLL is locked on a frequency. Also see acquisition mode.
- **two's complement** A means of performing binary subtraction using addition techniques. The most significant bit of a two's complement number indicates the sign of the number (1 indicates negative). The two's complement negative of a number is obtained by inverting each bit in the number and then adding 1 to the result.
- **unbuffered** Utilizes only one register for data; new data overwrites current data.
- unimplemented memory location A memory location that is not used. Writing to an unimplemented location has no effect. Reading an unimplemented location returns an unpredictable value.
   Executing an opcode at an unimplemented location causes an illegal address reset.
- V —The overflow bit in the condition code register of the CPU08. The CPU08 sets the V bit when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow bit.
- **variable** A value that changes during the course of program execution.

Technical Data MC68HC708MP16 — Rev. 3.1

- **VCO** See voltage-controlled oscillator.
- vector A memory location that contains the address of the beginning of a subroutine written to service an interrupt or reset.
- voltage-controlled oscillator (VCO) A circuit that produces an oscillating output signal of a frequency that is controlled by a dc voltage applied to a control input.
- **waveform** A graphical representation in which the amplitude of a wave is plotted against time.
- wired-OR Connection of circuit outputs so that if any output is high, the connection point is high.
- word A set of two bytes (16 bits).
- **write** The transfer of a byte of data from the CPU to a memory location.
- **X** The lower byte of the index register (H:X) in the CPU08.
- Z The zero bit in the condition code register of the CPU08. The CPU08 sets the zero bit when an arithmetic operation, logical operation, or data manipulation produces a result of \$00.
