The data published here has been compiled by Sylvania from various sources, and while believed to be accurate, no responsibility can be assumed in case of error.

Introduction

This book contains characteristics and ratings for over 750 television picture tubes. Both color and black and white types are included. All popular types are presented plus many older types for which there is still some replacement interest.

To make this book a complete and most useful reference guide, some types have been included which may not be currently available from Sylvania. This data can be useful in cross referencing types and finding Sylvania replacements for older, hard-to-find picture tubes. Consult Sylvania's current price list for available types.

Sylvania has been manufacturing cathode ray tubes since 1932. To date, 37 million tubes have rolled down the production line, an average of one tube every 20 seconds, every working day, 24 hours a day over 34 continuous years. The vast experience and know-how gained is reflected in today's Color Bright "85®'s", Color Screen "85's", and Silver Screen "85's".

37,000,000 television picture tubes

Many improvements have been incorporated into Sylvania's line of picture tubes over the years, such as: larger screen sizes, shorter lengths, aluminized screens, implosion protection systems, rectangular faceplates, greater life and reliability, and last, but far from least, Sylvania's New Rare Earth Phosphor and unique screening method plus stabilizing features which gives color pictures the brightest, truest color ever achieved.

Sylvania is the only manufacturer of cathode ray tubes with complete facilities for fabricating all tube components (except glass) from raw materials. An integral Parts Division and Chemical and Metallurgical Division permits the highest quality control throughout all stages of manufacture. Sylvania's experience in glass handling and glass technology related to electronics extends back to the beginning of the industry.

Sylvania color bright "85®" picture tubes—a complete color line

Sylvania began manufacture of color picture tubes in the early 1950's. During color television's infancy Sylvania supplied picture tubes to the industry and was among the leaders in development of improvements in tube design.

Now in the midst of a spectacular color boom, Sylvania stands ready with a full complement of color picture tubes. In addition to supplying the 21" round types for replacement purposes, Sylvania's line now includes rectangular types in sizes 15", 19", 22", and 25". These new rectangular tubes are shorter in length providing cabinetry with slim modern design. All use the ultrabright Rare Earth Phosphor Screen developed by Sylvania. Brightness has been increased significantly and colors are true and sharp. The new phosphor also provides a much brighter monochrome picture.

Sylvania also developed a superior screening process which optimizes brightness and eliminates problems inherent in other systems.

One method of screening generally used is to intimately mix the photoresist and phosphor in a wet slurry and apply it directly to the panel while rotating and tilting it for uniform distribution.

The Sylvania method is to deposit a photoresist solution on the panel and then deposit the phosphor by a dry process. The phosphor is ejected as a cloud of dust from a dry spray unit, and settles uniformly into the photoresist.

The basic color tube screening process consists of sequentially depositing the three primary color fields consisting of three individual sets of dots. Approximately 400,000 dots per color field are deposited. The dots measure about 0.015 to 0.018 inch in diameter.

The three primary color fields are properly oriented on the panel (inside surface of the faceplate). The panel is first coated with photoresist and green phosphor; and is then exposed (through the aperture mask) via an ultraviolet light source and optical system that provides an analogy between the electron optics of the tube

and the light optics of the exposure unit. In processing, the photoresist and phosphor is washed away from the unexposed panel areas, leaving the polymerized insoluble dot islands behind. The process is then repeated twice for the sets of blue and red dots. An aluminum reflecting surface is deposited on the back of the tri-dot screen to enhance brightness and contrast, and provide electrical conductivity.

The advantages of the Sylvania system are as follows: (1) Problems of phosphor contamination and deterioration due to milling action and breaking of crystals are minimized. (2) Phosphor crystals are maintained as whole crystals, with considerable latitude in choice of particle size and crystal form. Brightness is optimized as a result. (3) The Sylvania system provides production flexibility in handling various sizes and shapes of tubes, and in using and evaluating production materials and processing.

To enhance the features gained by the Rare Earth Phosphor and new screening process, Sylvania has introduced other improvements in the Color Bright '85" line. These stabilizing features prevent changes in color registry during the initial warm-up period and over the life span of the tube.

This is accomplished by a three part program encompassing: (1) A true tempered screen (glass faceplate stabilized to predetermined dimensions). (2) Computer controlled precision alignment between faceplate and shadow mask. (3) Cross-hair indexing for positive positioning of electron gun and optimum beam alignment.

Other features of the Sylvania color line include Bonded Plate Safety Panels to eliminate need for a protective window in the cabinet, and treatment of faceplate to reduce reflection.

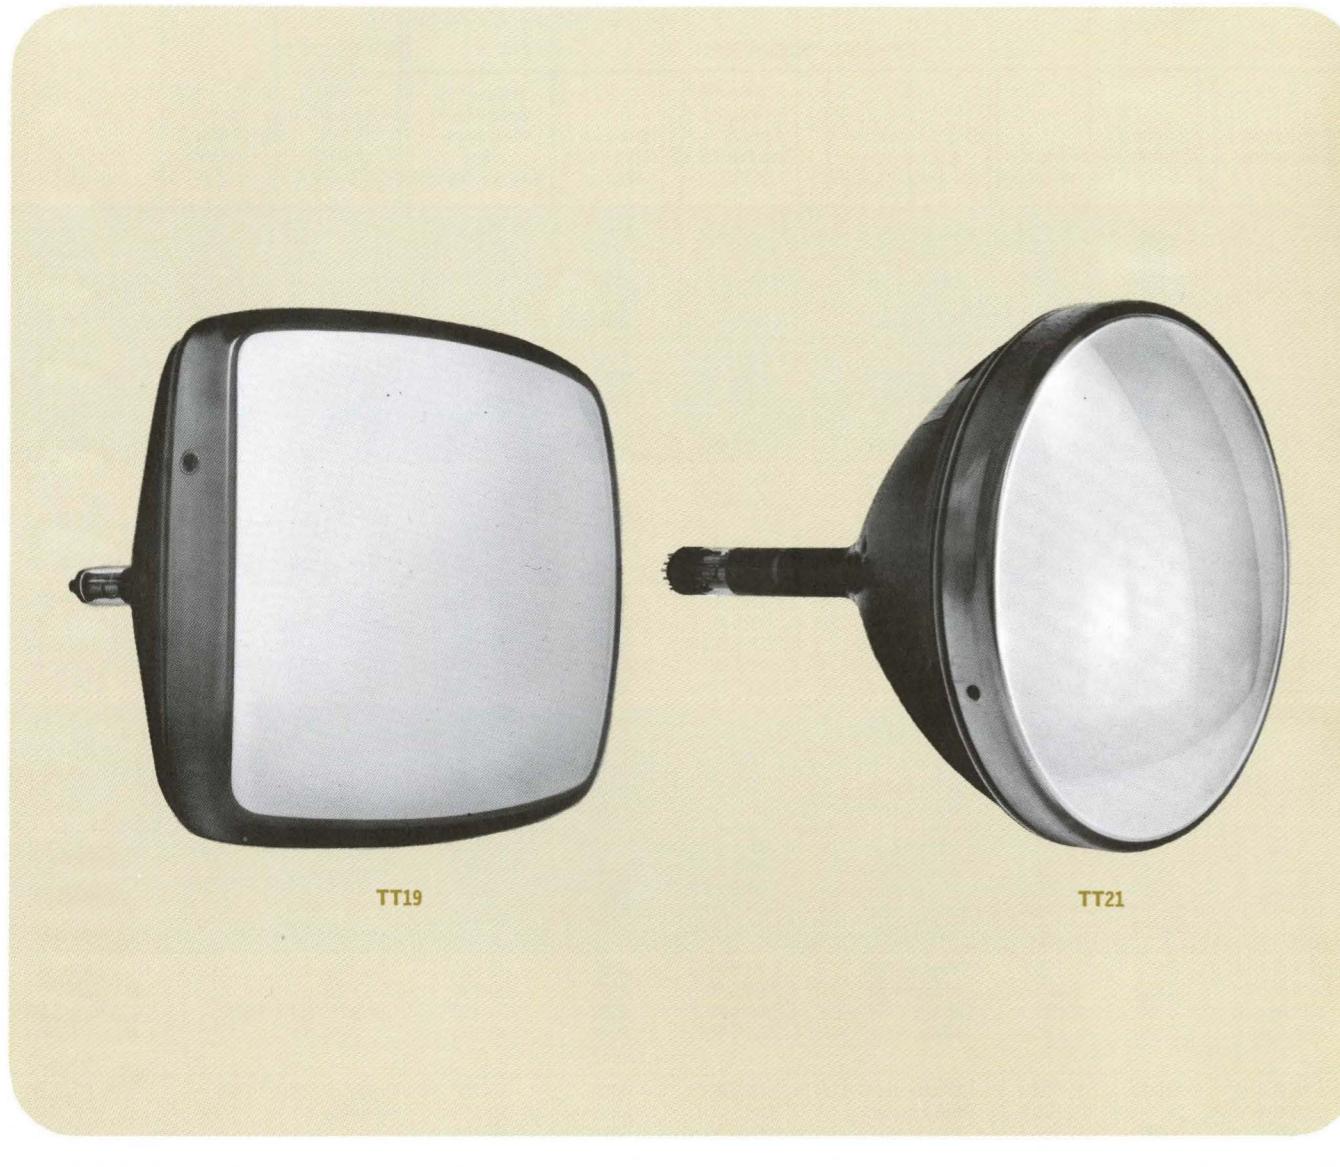

New expanded production facilities insure an adequate inventory of color tubes in all sizes for prompt shipment. For more information on Sylvania Color Bright '85®" picture tubes contact your nearest sales representative.

Basing Diagrams—Page 9

These tubes are electrically equivalent to 19", 90° rectangular and 21", 70° round color picture tubes used by all major manufacturers. They can be adapted to check all popular color picture tubes. Additional technical information on these tubes and on their application in TV receiver servicing is available on request.

Sylvania silver screen "85®" picture tubes—the finest in monochrome

Dealers everywhere have long recognized Sylvania's Silver Screen '85®' as the quality picture tube of the industry.

Time and time again tests have proved that the Silver Screen '85' gives the sharpest, clearest, brightest reception, and the longest tube life performance. So it's a natural conclusion that dealers insist on installing the Silver Screen '85' when a customer wants his set to work like new again—or better than new!

To begin with, the phosphors that are so important to screen brightness are rigorously controlled during their manufacture in Sylvania's own modern phosphor plant. And to assure the highest quality, these phosphors undergo more extensive testing upon arrival at Sylvania's picture tube plant. Absolute testing controls over these critical phosphors are the first of many steps taken to insure the brightest screens possible for the Silver Screen '85'.

Sylvania also takes extra precautions during the screening process in the preparation and storage of the screen solution. The solution is actually stored in a tile-lined room, and is filtered through large stainless steel filters before it is allowed to flow out of the solution room. This protects the phosphor from impurities that could cause spots, holes, or dirt specks on the screen.

Special safeguards are also taken to guarantee a consistent, uniform screen for each and every bulb. Transparent plastic reservoirs are filled automatically by electrically controlled devices and supply each Silver Screen '85' with exactly the right amount of phosphor.

To eliminate the possibility of a slight change in temperature destroying the edge-to-edge color of the screen, or producing dark centers, Sylvania rigidly maintains atmospheric conditions. This is accomplished through air filters and air conditioners that eliminate dust in the air during the screen-settling process. Also the warm air that is used to dry and set each screen has, itself, been carefully filtered and predried.

These steps are only the measures Sylvania

takes during the processing of every Sylvania screen. Add to these the many, many extra precautions that are taken during the complete production of the Silver Screen '85' tube.

New or improved manufacturing techniques now employed by Sylvania in the production of Silver Screen '85' picture tubes include:

Improved aluminizing distribution and thickness

To reduce center-to-edge gradations in aluminum thickness, an ideal combination of the aluminizing coil, coil shield, and support has been adopted. At the same time, this has permitted Sylvania to increase the aluminum thickness by approximately 25%, thus providing maximum resistance to electrical burning.

"Better intelligence" on focus spacing

Process control information and feedback of data to the Production Department has been increased to assure uniformity of G3-G5 focus spacing, tube to tube.

Better external conductive coating

An improved water-base external conductive coating, which exhibits greater resistance to peeling under high humidity, has been adopted. To obtain higher conductivity, improved spray techniques and equipment are now being used in production.

Advances in production of high vacuum

Extremely tight standards and procedures have been established to measure the effectiveness of each exhaust cart's vacuum system. In addition, a new method of determining minute leaks in the vacuum system is in effect, and any questionable exhaust carts are removed from production.

Exhaust emission testing to higher minimum limits

Each tube is checked to significantly higher minimum emission limits off the exhaust machine. These limits control the effectiveness of our processing, exhaust machine, mount parameters and operator techniques.

More severe life test conditions

Tubes are being run at higher average and higher peak current conditions to provide information on the ability of the tube to give satisfactory performance under these conditions, thus provide additional safety factor in the field. In addition, tubes are being run on life beyond normal life hours to add to our information and provide extended life expectancy statistics.

In stepping up the Silver Screen '85®' reliability program, Sylvania has not left a stone unturned. The following innovations concern Sylvania's precision electron gun mounts:

Control of cathode emission

To provide improved coating density control and to assure greater uniformity of cathodes, Sylvania's quality sampling program was intensified. Each lot of coated cathodes is carefully checked on a sample basis. Sylvania manufactures its own emitter coating material at its Tungsten and Chemical Division, this allows close

control of the precise chemical and particle size measurements which are necessary to obtain the desired coating characteristics.

New plastic and metal containers for mount parts

Plastic and metal containers are in use for parts transfers in the Mounting Department.

"Fresher" mounts

Tighter scheduling of mount production/inventory results in using "fresher" mounts in each tube. Also, heated mount transfer carts and plio-film bags are employed to reduce exposure to plant atmosphere.

It is doing "something more than is required" that distinguishes the manufacture of the Silver Screen '85' throughout. That's why you can install Sylvania picture tubes with utmost confidence. And that's why your customers are satisfied with the brightest, clearest, sharpest reception from any picture tube available.

Sylvania "balanced optics" electron gun

Constant refinement and improvement by Sylvania engineers has resulted in the advanced "Balanced Optics" electron gun, heart of every Sylvania picture tube. "Balanced Optics" describes the cumulative result of a variety of refined techniques, including:

- Micro-sheen metal surfaces
- Hair splitting spacing and tolerance controls
- Micrometric design techniques
- New electrode contours
- Corona suppression
- Beam guard and halo control
- Optimized performance for each neck length
- Planar focus

All of these improvements add up to important benefits—full picture power; pinpoint focus; improved drive characteristics; and brilliant, high-resolution high lights!

Notes—Pages 36 and 37

Basing Diagrams—Pages 34 and 35

These three types have self-focusing guns, do not require ion trap magnets, and have no external coating. One of them can be used as a TV receiver check tube for almost any of the listed picture tube types. Additional

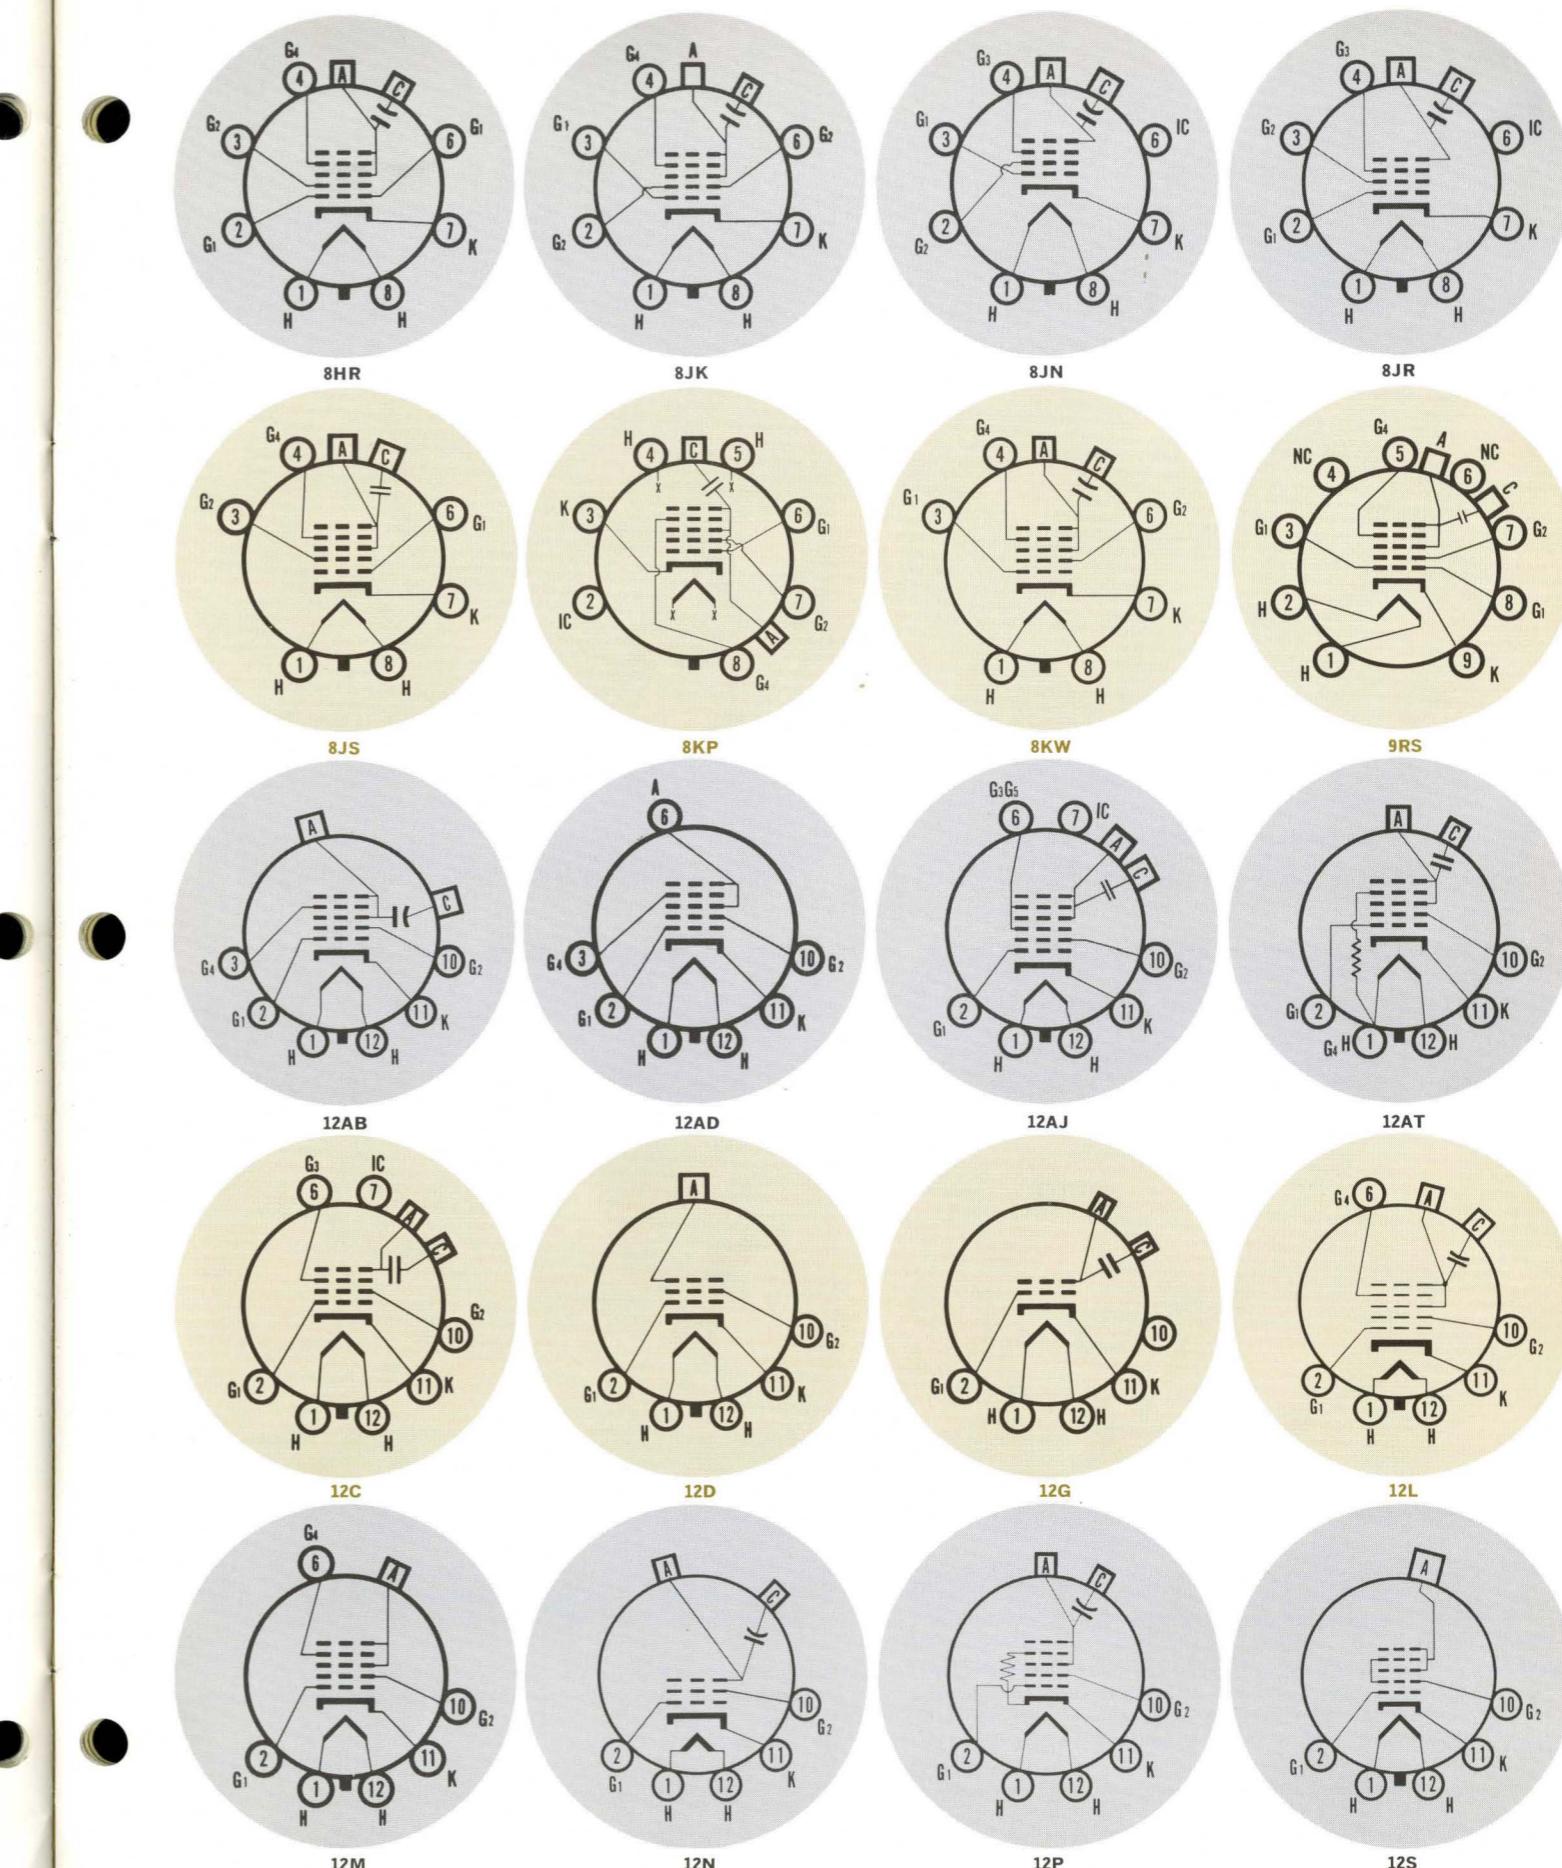

technical information on these tubes and on their application in TV receiver servicing is available upon request.

basing diagrams (monochrome tubes)

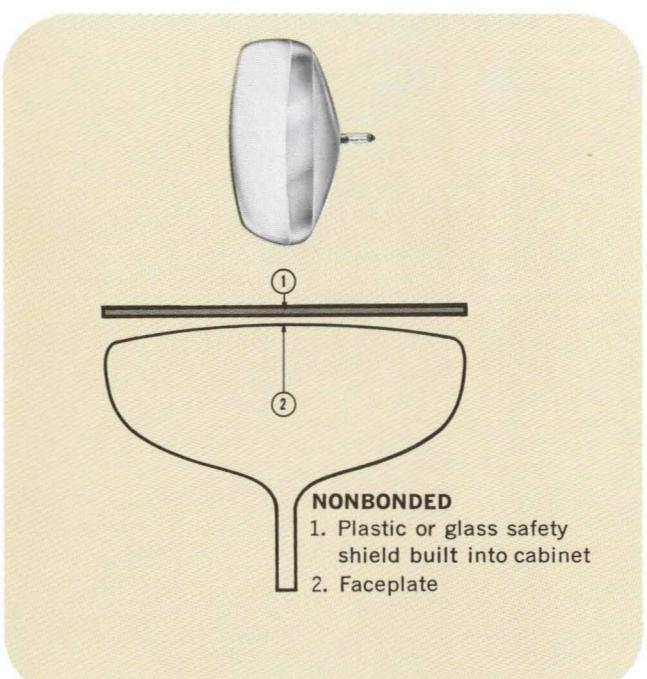

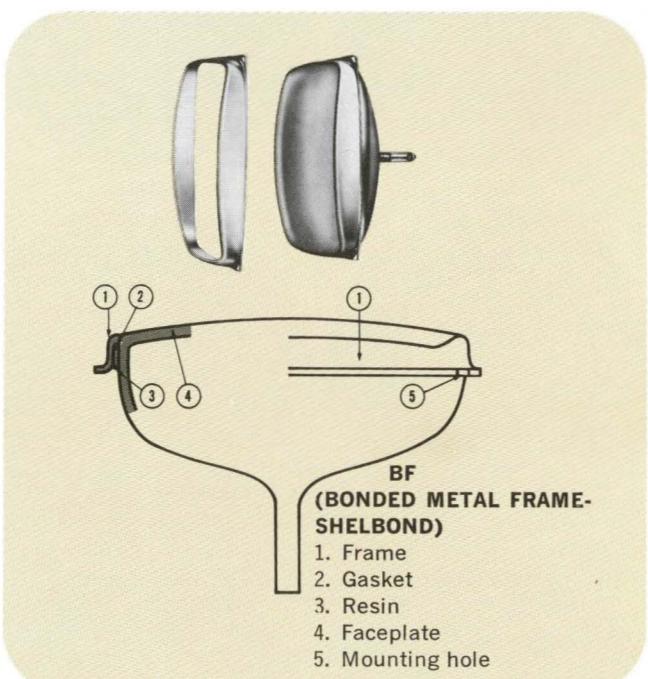

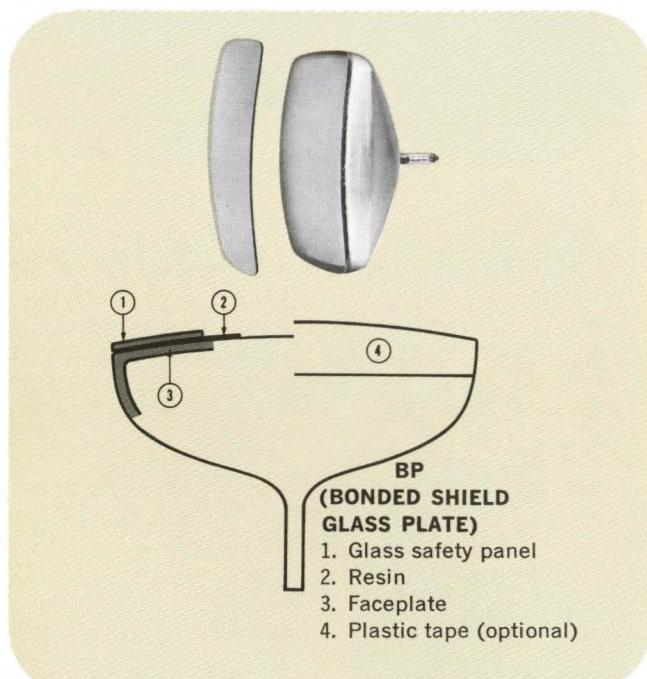

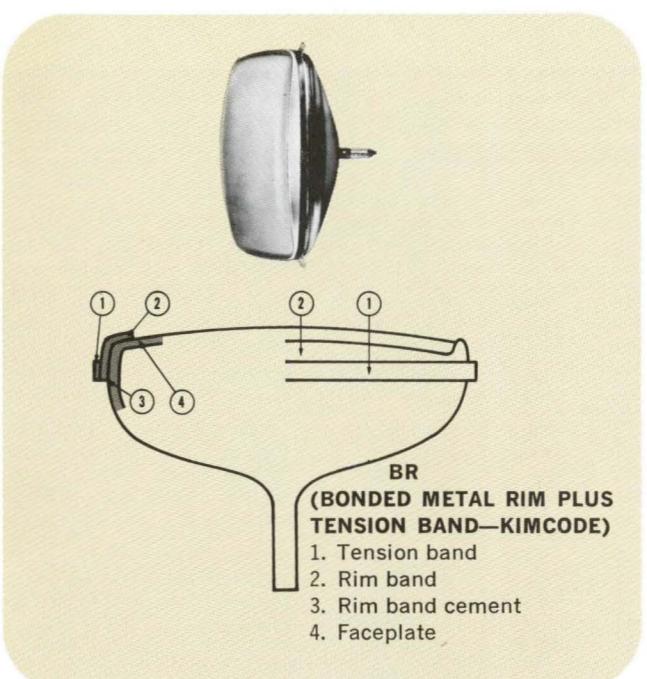

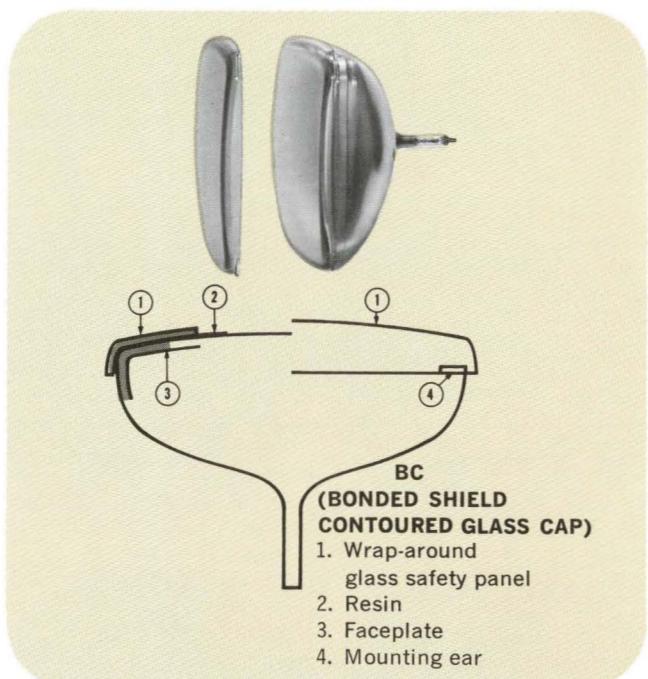

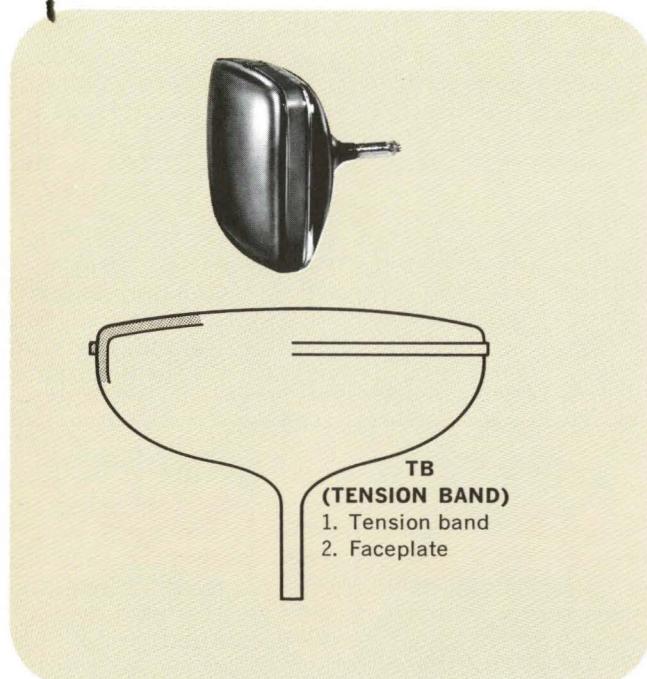

basing diagram symbols

- A Anode
- C Conductive j Coating
- H Heater
- G1 Grid No. 1
- G2 Grid No. 2, etc.
- K Cathode
- Locating Lug
- Bulb Terminal

notes:

◆ 94°, 110° and 114° types have a nominal neck diameter of 1½". All other magnetic deflection tube types have nominal neck diameter of 1¾". Color tubes listed have nominal neck diameter of 2" for the round types and 1¾" for the rectangular types.

▲ All Sylvania television picture tubes (except as noted in the Remarks Column) feature controlled heater warm-up time of 11 seconds for operation in receivers employing series heater strings.

● Design Maximum Ratings are limiting values that should not be exceeded under the worst probable operating conditions.

*Ion Trap

N - No Magnet
S - Single Magnet
D - Double Magnet
I - Internal Magnet

△ Does not include the dynamic convergence component.

m Maximum

BC-Bonded shield (contoured glass cap)

Features a permanently bonded-on wrap-around panel that provides added viewing safety. Mounting ears are located on the four corners of the bonded shield to allow mounting of the tube, thereby eliminating the use of complicated mounting devices. This design is currently available in the 19" and 23" sizes only.

BP-Bonded shield (glass plate)

This design is adaptable to any size and shape of bulb. The panel, which fits only over the frontal surface, is molded, cut to size, shaped, and then bonded to the tube by Sylvania. Currently popular tube sizes incorporating this type of Bonded Shield are 16, 19, 21, 23 and 27".

BF-Bonded metal frame (shelbond)

Features a resin-filled steel shell encasing the critical area of the picture tube. Integral mounting ears on the shell eliminate the need for additional brackets. Bonded Frame is available in 11, 12, 19, 23 and 25" designs. Other tube sizes utilizing this design may be adopted.

BR-Bonded metal rim plus tension band (Kimcode)

The new design employs a special heavy weight bulb with a rim band secured around the edge of the tube. A tension band, joined by a clamp, fits directly over the rim band, placing the faceplate in proper compression. This design is available in 16, 19, and 23" tube sizes, and other tube sizes utilizing this design may be adopted. There are versions in which the tension band is welded, and these are generally interchangeable with the clamped types.

Certain types employ mounting ears on the four corners of the rim to allow mounting of the tube, thereby eliminating the use of complicated mounting devices. Several versions of mounting ears exist, and specific type numbers should be specified to assure correct interchangeability.

BL-Bonded laminated plastic shield

Incorporates a laminated plastic sheet which is coated with a plasticizer and vacuum-formed directly on the face and partly down the sides of the tube. Used only on a few small tubes for portables. (Not illustrated)

Nonbonded

Has a standard glass protective plate mounted in cabinet in front of the tube. This may allow moisture and dust particles to collect on the tube faceplate and inner surface of the safety panel. The protective plate gives the regular tube a total of four reflective surfaces compared to the bonded types which have only two reflective surfaces—a total of 50% more reflection in the regular tube and separate safety plate combination.

*Implosion protection

TB-Tension band

Employs a metal band which places the faceplate in proper compression. Currently used on small screen types for portable television sets.

Sylvania picture tube

* Replacement information is based primarily on electrical and mechanical similarity of the picture tube types covered. The technician should make certain that replacement is in accord with all safety precautions required by the TV receiver for picture tube insulation or mechanical mounting. For all applications, the external conductive coating must be grounded and care must be taken that the coating does not contact any support straps or brackets which might result in voltage appearing on trim or external hardware of the receiver.

A Replacement type does not require an external ion trap magnet.

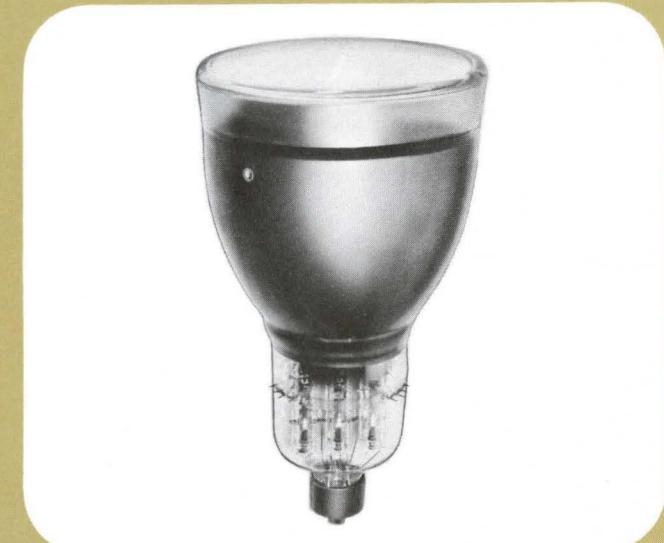

B Requires slight modification in tube mounting. See article "Color Fidelity for Older Color Receivers" published in Summer-Fall 1965 issue of SYLVANIA NEWS.

C The 21EAP4 has a 2.35 volt/600 milliamper heater, and type 21EVP4 employs a 2.68V/450 ma heater. The 21FDP4 has a 6.3 volt/600 milliampere heater. Instructions for necessary minor set modification are packaged with each replacement type 21FDP4.

D The high voltage filter condenser if any, must be removed from receiver since it is replaced by the capacitance of the tube.

E Type 24AVP4 has a 2.35 volt/600 ma heater. Type 24BEP4 has a 6.3 volt/600 ma heater. Instructions for minor set modifications are packaged with each 24BEP4.

Special tubes (industrial & military cathode ray tubes) available from Sylvania

- Oscilloscope Tubes
- Radar Tubes
- Video Recorders
- Flying Spot Scanners
- Monitors
- High Resolution Photo Recorders
- Low Heater Power Tubes

- Multi-Gun Tubes
- Monoscopes
- Electrostatic Charge Printing Tubes
- Fiber Optics Tubes
- Character Writing Tubes
- Rear Window Tubes

how to handle and install TV picture tubes and large cathode ray tubes

"An ounce of prevention is worth a pound of cure" . . . best rule to follow when handling and installing Television Picture Tubes and other large Cathode Ray Tubes. Since Picture Tubes are large elements constructed of glass and enclosing an evacuated space they must be protected from severe shock . . . handled with extreme care. The normal precautions taken when working with any high voltage circuits, should be observed. Specific procedures and proper precautions are outlined here.

Mechanical handling:

1. Protective face shield or goggles and gloves should be worn, for personal safety, whenever handling large picture tubes.

2. Picture tubes should be removed from the shipping carton face up and supported by the sides of the large portion of the tube. Handling of large picture tubes by the neck is unsafe and should be avoided at all times. It is obviously the weakest part of the tube and most easily injured. Therefore, the neck should always be kept free of strain and protected from striking other objects.

3. Picture tubes should be inserted into sockets by supporting the tube at the large end and holding the neck only for guiding the base pins into the socket.

4. The tubes should be removed from their sockets in the same manner as they are inserted, supported at the large end.

5. When not installed in a television receiver or other equipment, pictures tubes should be stored in shipping cartons with the covers closed.

6. Avoid placing picture tubes on a table or bench where there is any possibility of the tube rolling off. This is very important.

7. Scratching the surface of a picture tube weakens the glass and may be the cause of the tube imploding. If it is necessary to place a tube elsewhere than in its shipping carton, a piece of felt or other soft material should be placed under it.

8. Picture tubes should be used for display purposes only after the vacuum seal has been broken. Economy dictates that only wornout, or otherwise worthless, tubes be used for this purpose. The vacuum seal may be broken in the following manner.

a. Place the tube in a shipping carton, face down, with enough soft packing material underneath so that the base will extend above the closed cover.

b. Drill a $\frac{1}{4}$ -inch hole in the end of the locating lug or break off the lug entirely with a sharp blow or with pliers.

c. Using a small file or cutting pliers, make a small hole at the tip of the exhaust tube. Care should be used to make a small hole in the tip so that air will enter the tube slowly and not disturb the screen coating. In tubes using a metal exhaust tube a small three-cornered file may be used to make a small hole. The bright getter deposit on the neck should change color almost immediately. As a precaution, some time after the small hole has been made, it is well to break off the tip completely. The tube cannot implode after the vacuum seal has been broken, but it should still be handled as carefully as any other glassware of equal weight.

9. Discretion should be exercised in the disposal of tubes which are no longer useful to avoid possible legal liability. A safe method of breaking up a tube for disposal is to place it in a carton, seal the carton, and drive a metal rod through the carton into the face of the side of the tube. The broken parts may then be

disposed of in the usual manner.

10. If a tube does break causing small cuts in the skin, such cuts should be washed carefully to be certain that all dirt and other small particles are removed. While the materials used for coating Sylvania picture tubes are not considered to be toxic, there is the possibility of an unusual personal sensitivity or allergy in some persons.

Handling high voltage circuits:

1. Stand on dry wood, a rubber mat, linoleum or other dry insulating material when working on any electrical circuit.

2. One hand should be kept in a pocket to reduce the effects of accidental shock.

3. Respect all safety interlock switches and be certain that they are in good working condition.

4. Be certain that high voltage condensers are discharged before working on the circuit. Bleeder resistors may be open.

5. Some picture tubes have a conductive coating on both the inside and outside surfaces to form a condenser. This condenser should be discharged before the tube is handled. Even a slight unexpected shock might cause a tube to be dropped.

6. In some circuits where the picture tubes operate with a voltage on its second anode higher than its specified maximum rating, or higher than 16,000 volts whichever is less, it is possible that low intensity X-rays may be emitted. Therefore, X-ray radiation shielding may be necessary to protect against possible danger of personal injury from prolonged exposure at close range if the tube is operated at such high voltages.

7. Take the time to be safe.
