PART 1

DIAGRAMS & CIRCUIT DESCRIPTION

Logic diagrams represent a symbolic approach to electronic schematics. By using symbols to represent building block circuits, the diagram becomes easy to read if the reader understands the function of the symbols. In Control Data Corporation logic, two signals, a logical 0 ("0") and logical 1 ("1"), are the possible input or output conditions of a circuit. A circuit with an output of "1" is "up" and a circuit with an output of "0" is "down". Detailed descriptions of logic symbols and their associated building block circuit cards are contained in the appropriate printed circuit manual (1604 and 3600 Card Types). Refer to the Literature Distribution Center Catalog for the publication number and latest revision level.

STANDARD LOGIC SYMBOLS

Standard logic diagram symbols for Control Data equipment using 1604- or 3600-type cards are inverters, flip-flops, control delays, capacitive delays, inductive delays, and line drivers and receivers.

Inverters

An inverter is a logic element which provides an output that is an inversion of its input. When more than one input is provided to an inverter, "1's" take precedence over "0's" and drive the output of the inverter to "0". Because any "1" input of several inputs drives the output to a "0", an inverter may be considered an inverting OR (NOR) gate when more than one input is present.

Figure 1. Inverter Symbols

Acceptable conventions for showing multiple OR inputs are given in Figure 2.

Figure 2. OR Circuit Conventions

An AND gate requires that all its inputs be "1's" in order that its output be a "1". If one or more of the inputs to an AND gate are "0", the output is a "0". Figure 3 illustrates conventions for showing AND gates feeding an inverter.

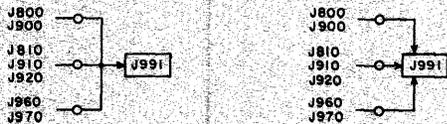

Figure 3. AND Circuit Conventions

Figure 4 illustrates a combination AND/OR input.

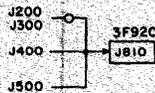

Figure 4. AND/OR Circuit Convention

KEY TO LOGIC SYMBOLS

(STANDARD 1604 OR 3600 CARD TYPES).

Flip-Flops (FF)

The flip-flop (FF) is a storage device with two stable states - designated as Set and Clear - and is composed of two or more inverters. The logic symbols (Figure 5) are formed by the combination of inverter symbols. By convention, Set inputs and outputs are shown in the upper part of the symbol and Clear inputs and outputs are shown in the lower part of the symbol.

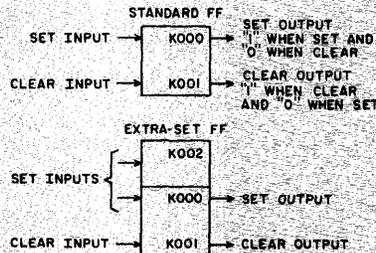

Figure 5. Flip-Flop Symbols

Figure 6 illustrates the interconnection of inverter symbols to form a flip-flop symbol. The term numbers assigned to each flip-flop are the term numbers of the internal inverters as seen by comparing the terms in Figure 5 with those in Figure 6. Notice that the Set output is the output of inverter K001, and the Clear output is the output of inverters K000 and K002.

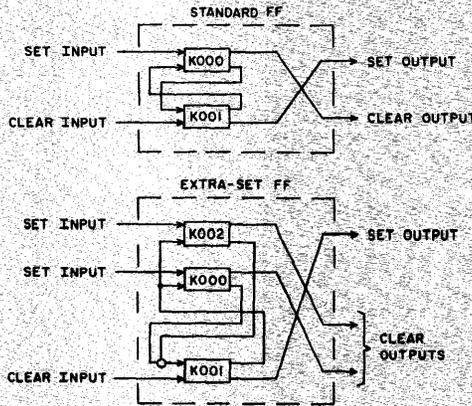

Figure 6. Internal Inverter Connections for a Flip-Flop

Control Delay

A control delay is a timing device consisting of an H term which receives the input and one or more V, Y, or N terms to provide the outputs. The H term is essentially a flip-flop with controlled feedback and occupies an entire printed circuit card. The output term(s) are inverter(s) located elsewhere on the logic chassis. The "1" outputs from a control delay are clocked pulses which are delayed one phase time from the "1" inputs. Clock inputs are not shown on the logic diagrams for any H, V, Y, or N terms; these terms, which control the start and duration of the delayed output pulses, may be found in the Equation Summary. Figure 7 illustrates two representative forms of the control delay symbol, with possible inputs and outputs labeled. Figure 8 shows the electrical connections for the two forms.

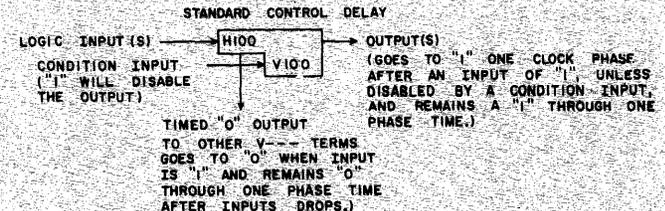

Figure 7. Control Delay Symbols

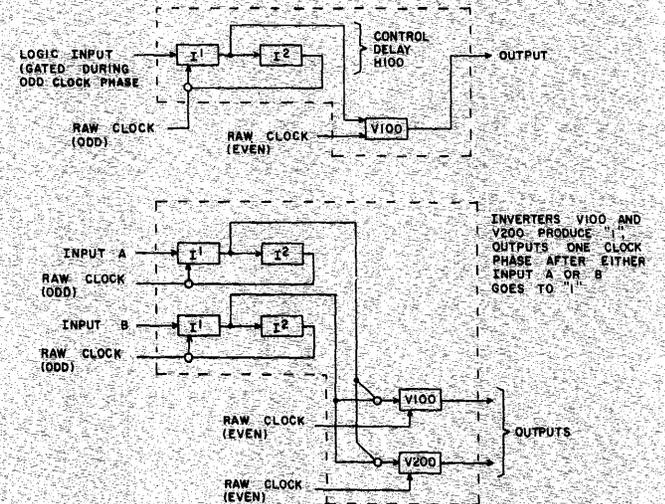

Figure 8. Electrical Connections for Control Delay

Control delays may have multiple inputs and/or multiple outputs. When a control delay has multiple output terms (i. e., more than one V, Y, or N term), each output term may have a separate conditioning input.

Capacitive Delays

A capacitive delay is used to delay the "1" input to a logic element. ("0" inputs are not affected by the delay.) Capacitive delays may be active or passive, depending upon whether or not transistors are used as part of the delaying circuit. Delay periods are checked by using a dual-trace scope connected to the input and output of the delay producing element. The actual connection points for the scope and probes vary for different cards and should be determined by referring to the Printed Circuit Manual.

Active delays may be recognized by the circuit letter always present as part of the card location. Pin numbers are also shown when external wiring is needed to connect the proper capacitance. In Figure 9, the pluggable delay uses this wiring to connect to capacitors on the same card. In the third example, this wiring connects to capacitors located on two separate capacitor cards.

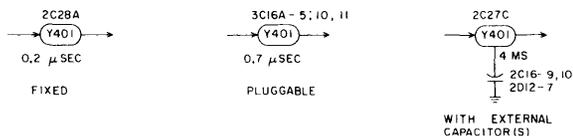

Figure 9. Active Capacitive Delays

All passive capacitive delays (Figure 10) are formed by wiring grounded capacitors, located on one or more capacitor cards, as an AND input to the affected logic element. For this reason, all passive delays show pin numbers to provide this external wiring data.

Figure 10. Passive Capacitive Delays

Capacitive delays may be adjustable or nonadjustable, depending on the card type and/or the external wiring connections on the card. When it is necessary to adjust the delay period in order to obtain specified circuit operation (usually done by varying a potentiometer in the RC network), a diagonal arrow is added to the delay symbol as shown in Figure 11.

Figure 11. Adjustable Capacitive Delays

Inductive Delays

An inductive delay is used to delay either the "1" or "0" input to a logic element or as a tapped delay line for timing of operations. The symbol for this delay is an elongated oval with a double vertical line just within the input end of the oval. When used as a tapped delay line, the inductive delay is terminated in its characteristic impedance. Inductive delays are identified

in the same manner as capacitive delays (except for the vertical lines) unless they are used as delay lines. On multi-section cards where no identifying circuit letters are present, pin numbers are shown adjacent to the input and output arrows. Figure 12 shows both kinds of inductive delays.

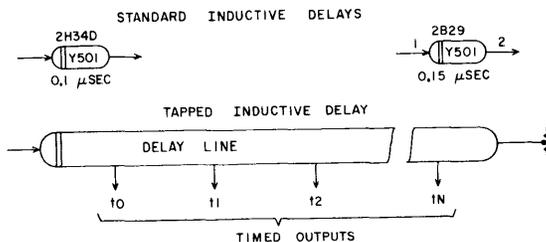

Figure 12. Inductive Delays

Line Drivers/Receivers

Voltage levels used to represent "1's" and "0's" on cables are different from those used for internal logic. The level shift to and from internal logic is made by line drivers and line receivers. These cards may be considered as inverting the signal electrically, but not logically. The letters commonly associated with these cards are L & M (1604) and R & T (3000 Series). A 3000 Series Receiver may also be used to perform a logical inversion by swapping the twisted pair wires. This usage is indicated by a circle on the input side of the symbol. In Figure 13, "1's" and "0's" have been added to clarify the logic states; they are not part of the symbol.

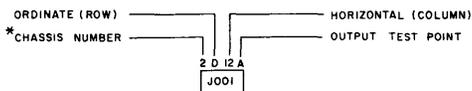

Figure 13. Typical Line Driver/Receiver Symbols

NON-LOGIC CONVENTION

The use of the double vertical bar, as shown in Figure 13, denotes a shift in signal voltage level from that used in internal logic. The double bar appears on the input or output side of the symbol, depending on which side connects to the non-logic-level signal. No particular voltage level is implied by the double bar - only that it is non-logic.

JACK ASSIGNMENTS

Each numbered term in the logic diagrams contains a jack assignment showing the physical location of that hardware element and the test point (circuit section) associated with it. For some card types, the test point letter is replaced by a pin number. For these cases, a card extender must be used in order to test that section of the card. Also, some symbols show no test point. This is because the entire card is used for one purpose (e. g. a single inverter, FF, or control delay). Figure 14 illustrates the inverter J001, with 2D12A representing its jack assignment.

*When most or all jack assignments are located on one chassis, the chassis numbers for that chassis are omitted. All multi-chassis devices include a chassis number as part of each jack assignment.

Figure 14. Jack Assignment Scheme

CABLE IDENTIFICATION

Cable connections are represented by the MIL-STD-15 symbol and identified as to connector location and pins used, as shown in Figure 15.

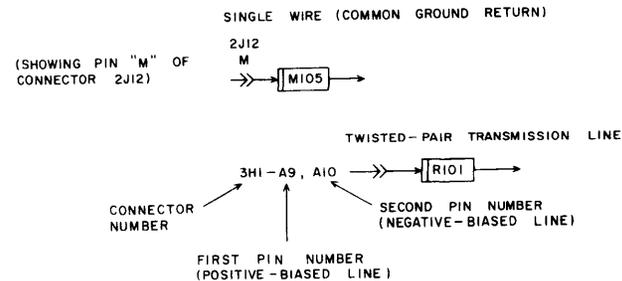

Figure 15. Cable Connections

SPECIAL LOGIC SYMBOLS

Nonstandard elements (special logic and/or non-logic elements) are represented by a special circuit symbol (generally a rectangle as shown in Figure 16). The special circuit symbol always shows the symbol designation, jack location, and the card type. Supplemental information may also be shown such as in the case of special delay cards which indicate the delay period. For detailed information refer to the specific card type in the appropriate Printed Circuit or Logic Module Manual.

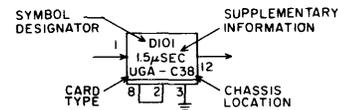

Figure 16. Symbol for Special Circuits

INPUT/OUTPUT DESIGNATIONS

Where several pages of logic are involved, a symbol index and term list (side cars) are incorporated within the manual. Also in certain instances such as special card types or on equipments for which no equation summary exists (as for peripheral devices) input and output pin numbers are indicated on each logic element as are the output destinations of the elements (Figure 17).

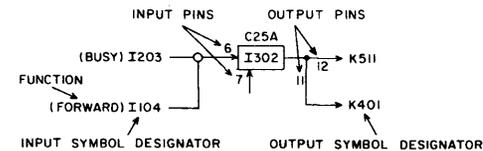

Figure 17. Input/Output Designations

UNIT SELECT

The controller can select any one of eight disk storage drives by applying a select module signal to receiver R012. If the disk storage drive is on-line, the following lines are returned to the controller:

1. Selected Module via T007. This line is used by the controller to check if the disk storage drive is selected.
2. Selected On Line, via T006. When the heads are loaded, this line indicates that the selected disk storage drive is available.

ADDRESS AND CONTROL BUS

The address and control bus consists of eight input/output lines which carry information between the controller and the disk storage drive. The function of the signals carried on these lines is defined by one of the accompanying select lines.

SELECT LINES

Set Difference

After the controller has computed the difference between the disk storage drive current cylinder address and the desired cylinder address, the controller applies a -Q set difference pulse to R008. This indicates to the selected disk storage drive that the address and control bus contains head positioning information. This information, indicating tracks-to-go to the desired cylinder, is then loaded into the decrement counter.

Set Cylinder

The -Q set cylinder pulse applied to R009, indicates that the address and control bus contains head positioning information. This information is used to reset the disk storage drive cylinder address register to the new cylinder address.

Set Head and Direction

The controller applies a -Q pulse to R010 when the address and control bus contains head select information and the cylinder access direction. The head select information (bits 4 thru 7) is gated into the head address register to select which head shall read or write. Bit 0 of the bus is applied to the Reverse FF (K214/215) to establish the direction of the next seek.

Control Select

The -Q level control select signal is applied to R011. When this signal is up, the address and control bus contains control information. Bit assignments and their functions are as follows:

1. Bit 0 - Write Gate, -Q level. Commands a write operation by enabling the write driver.
2. Bit 1 - Read Gate, -Q level. Commands a read function by enabling the read lines.
3. Bit 2 - Start Seek, -Q level. Initiates carriage positioning according to that previously specified by the Set Head and Direction tag.
4. Bit 3 - Reset Head, -Q level. Resets head address to zero.
5. Bit 4 - Erase Gate, -Q level. Commands an erase function by enabling the erase driver.
6. Bit 5 - Head Set, -Q level. Enables the head indicated by the head address register.
7. Bit 6 - Return to Zero Seek (RTZS), -Q level. Move heads in reverse to the home position, then forward to cylinder zero.

8. Bit 7 - Head Advance, -Q level. Increments the head address register so that the next head in order can be selected. This function can be used to select heads sequentially on a cylinder for multiple track reading or writing.

INDEX/SECTOR

Each cylinder is divided into 20 sectors. The controller knows which sector is under the heads by means of a sector disk which rotates with the disks. The sector disk has 21 notches in its outer rim. As the disk rotates, the notches cover and uncover photocells to generate sector pulses.

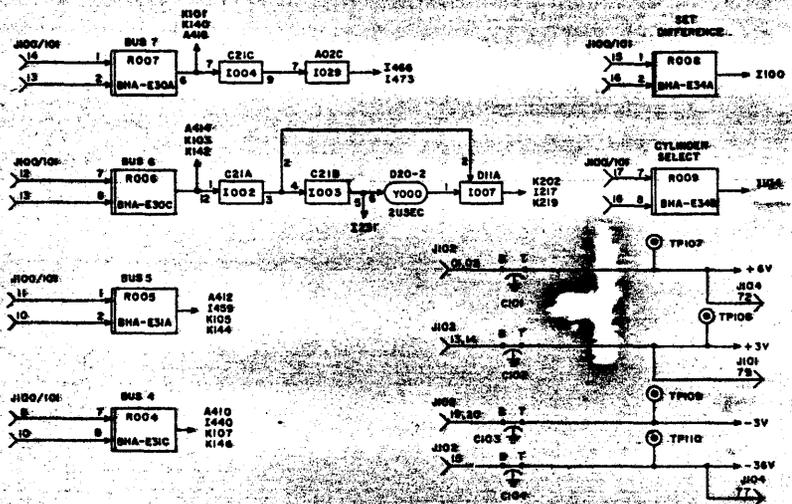

The starting, or reference, point is the index pulse. This pulse is generated by two notches close together on the sector disk. When light passes through both notches simultaneously, the output of I028 goes to "1". If the unit is selected and on line, T004 returns a selected index, -Q pulse.

END OF CYLINDER

If the heads are selected sequentially on a cylinder, the head address register is incremented by the Head Advance Command. While heads 0 thru 9 are selected, none of the AND gates into I026 are made. When the next head advance command is applied to R007 to advance the head address register from 9 to 10, the gate into I026 is completed. T005 returns a -Q level End of Cylinder signal to the controller to inform it that the last head of a cylinder has been used.

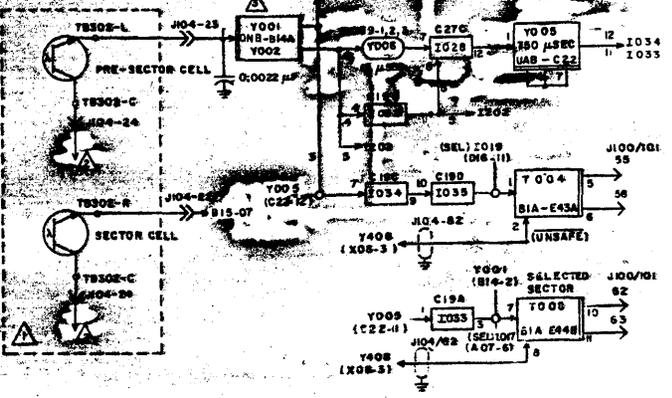

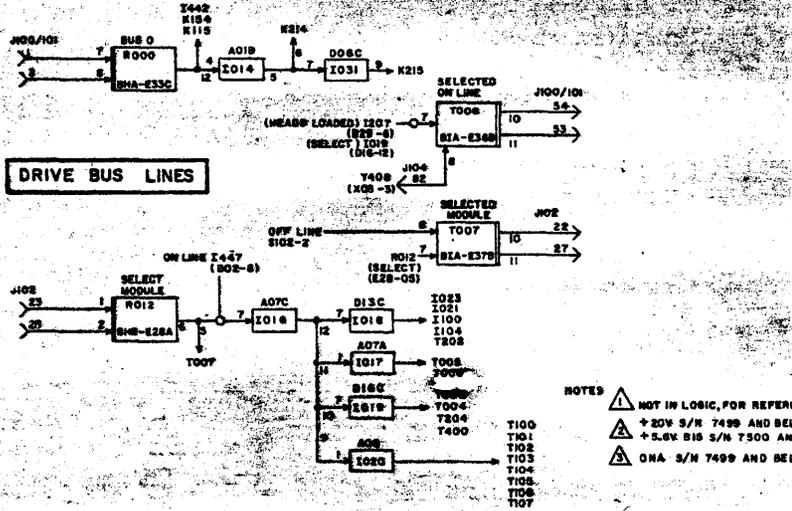

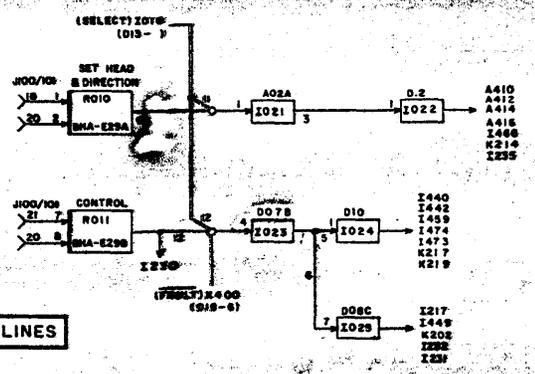

All input/output signals are Q or L levels or pulses. These signals are within the following voltage ranges:

+Q = +3.5 to +0.65 vdc, -Q = -0.5 to -3.5 vdc, +L = +6.28 to +2.0 vdc, and -L = +0.3 to 0.0 vdc.

CONTROL DATA CORPORATION PERIPHERAL EQUIPMENT DIVISION <small>INDIANAPOLIS, INDIANA 46201, 50410</small>	TITLE I/O LOGIC	PRODUCT 9461 SIZE C DRAWING NO. 45587700 REV BK DRAWN J.M.F. SHEET 1
	TITLE I/O LOGIC	

DECREMENT COUNTER

The decrement counter is set by the Set Difference input to the address and control bus. This select sets the counter to the number of cylinders to go during a seek. Direction of seek is controlled by the Set Head and Direction line.

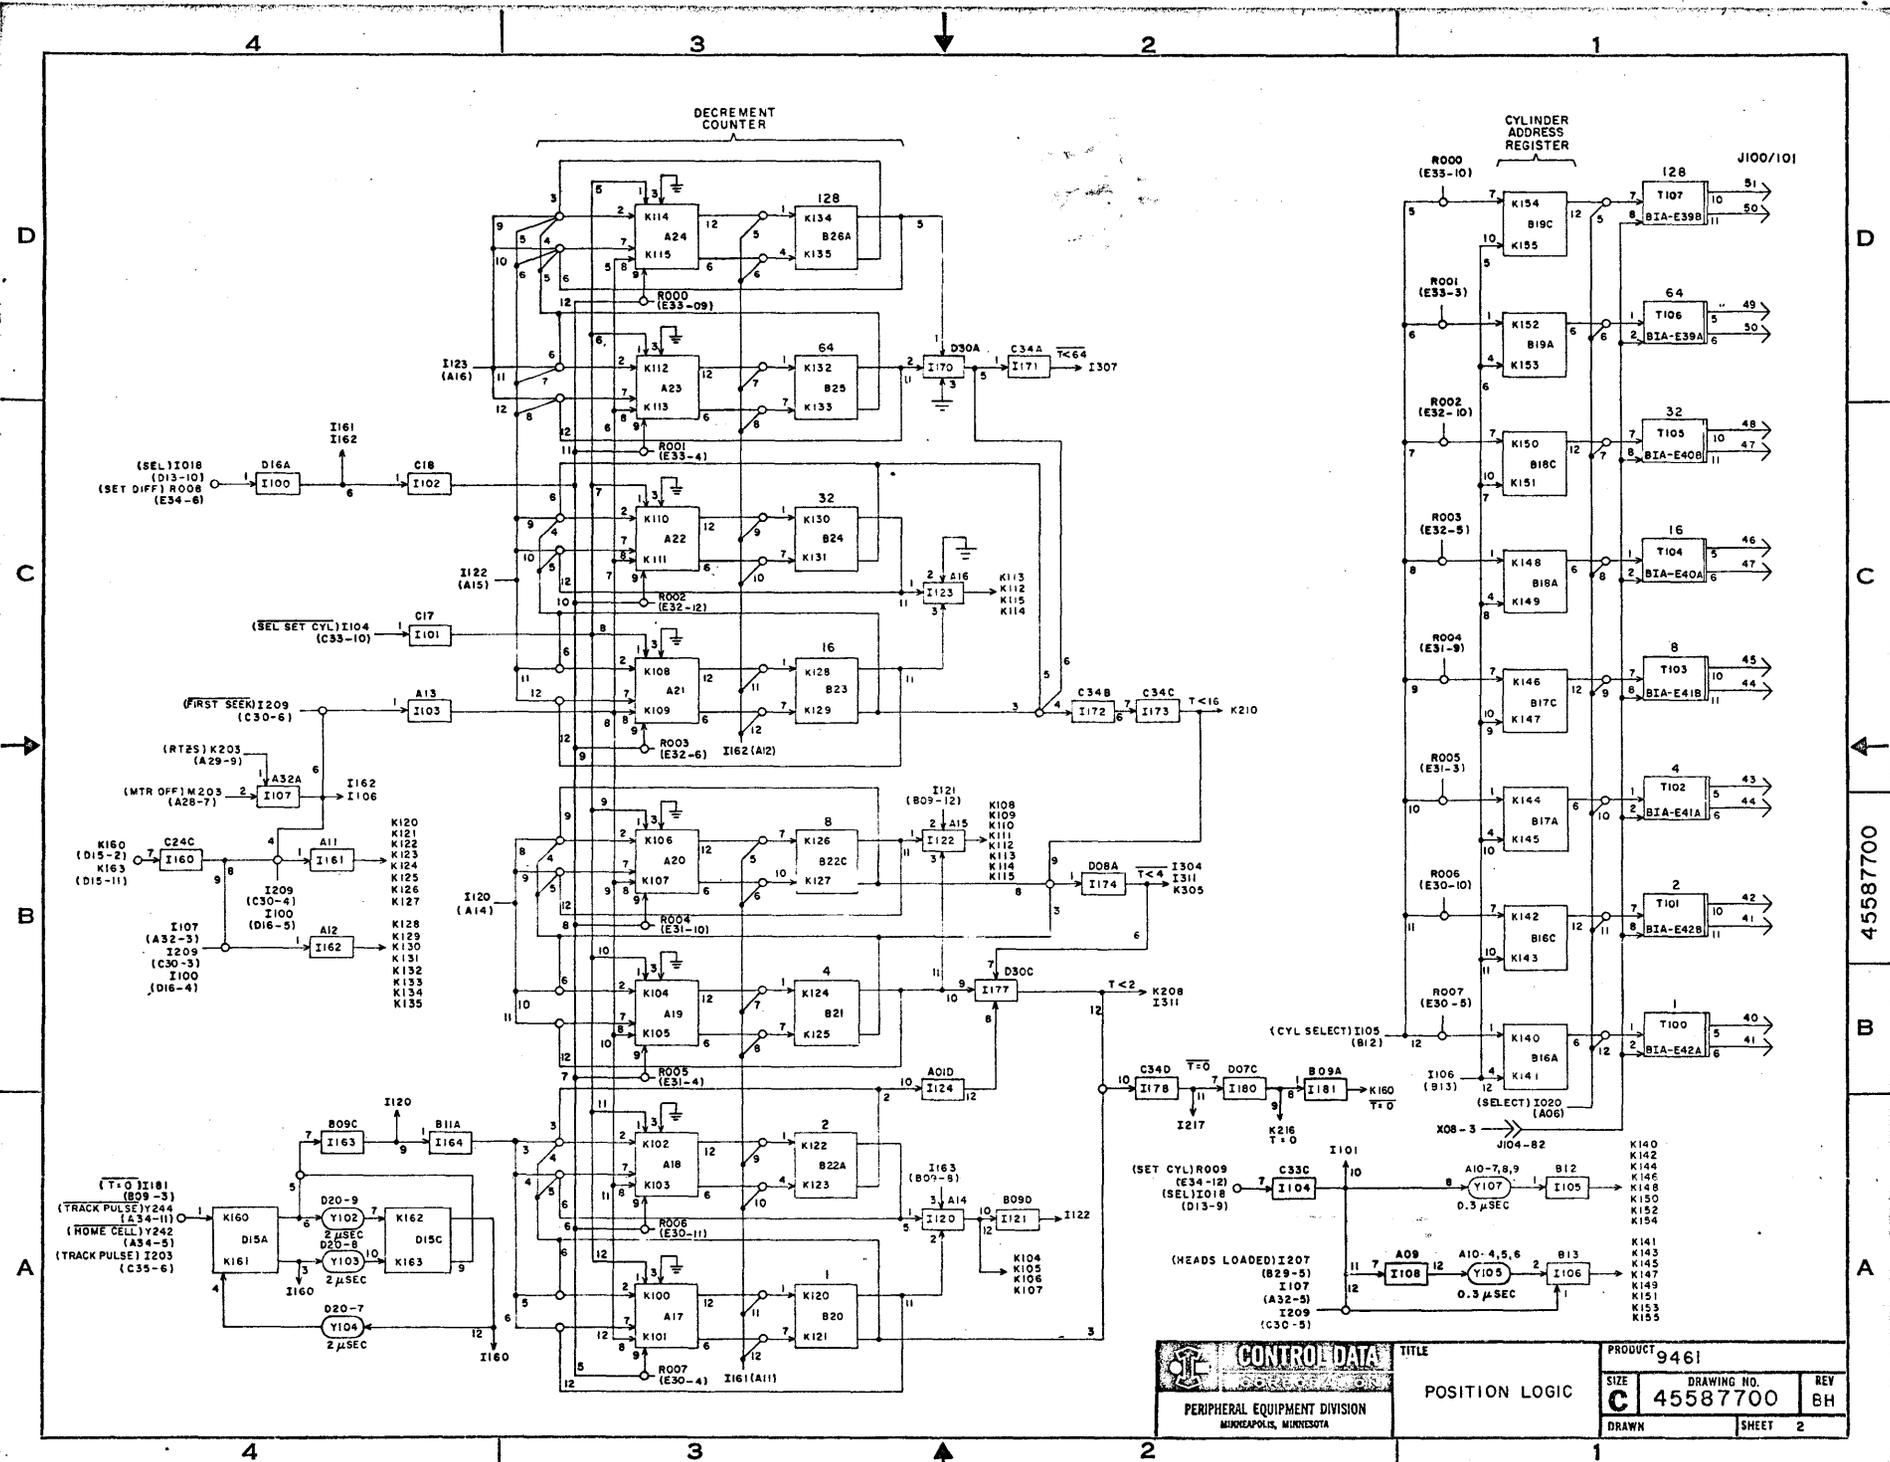

As the heads move toward the new cylinder, the trailing edge of each track pulse provides an enabling term to pulse generator K160/161 and K162/163. This pulse generator provides the two phase pulses necessary to decrement the counter. As the counter counts down towards zero, inverter I171, I173, I174, I177, and I178 decode the output of the counter to indicate the number of tracks to go. These lines will be used to control the speed of the carriage motor and, ultimately, to stop the heads on the desired track.

CYLINDER ADDRESS REGISTER

The cylinder address register is set by the Set Cylinder input to the address and control bus. The number stored in the register indicates which cylinder the heads are currently positioned on.

REV A

HOME CELL

The home cell is a photocell which receives light if the heads are positioned on an illegal cylinder (less than cylinder 00 or more than 202). This signal is used to detect a seek error or to position the heads on cylinder 00 during a return to zero seek or first seek.

DIRECTION CONTROL

The direction of carriage motion is controlled by the forward FF. The FF forces forward motion when it is set by any of the following:

1. Heads unloaded and first seek.
2. Home cell lights while driving in reverse.
3. After a seek has been completed.

The Forward FF is cleared by:

1. Return to zero seek.
2. Reverse seek command.
3. After heads are loaded during first seek.
4. When heads are unloaded with motor off.

The Reverse FF forces reverse motion by clearing the Forward FF. The Reverse FF is set by a set head and direction or if a forward seek error occurs. It is cleared at the end of the reverse seek or upon completion of the seek error recovery.

The RTZS (Return to Zero Seek) FF is set by a control select from the controller. Setting the FF clears the Forward FF to enable reverse drive to the home cell. RTZS FF clears when the home cell lights.

The Slow FF is set when tracks-to-go are less than sixteen. The output of the FF acts on the motion circuit to prevent the carriage from moving faster than 6 ips. The FF is cleared by any seek command.

Stop FF commands the carriage to stop. As the decrement counter counts down during a direct seek, the output of I177 goes to "1" on the trailing edge of the next to last track pulse (that is, when T²). On the leading edge of the next track pulse. Y243 goes to "1" to complete the AND gate to set the FF. The FF is cleared by an any seek command or a motor off and heads unloaded condition.

First Seek FF is used to initially load the heads. When the disks come up to speed, the FF sets. This sets the forward FF. When the heads are loaded, the Forward FF clears. Note that the First Seek FF is also set if a seek error occurs during a forward seek.

Seek Error FF senses an error if the home cell is uncovered during a direct seek. The FF is cleared upon receipt of a return to zero seek command or power-off seek.

DETENT

The Detent FF (K212/213) controls the detent pawl which locks the carriage on its specified track. When the FF is set, cards L200 and L201 are turned off. This deenergizes the detent coil, allowing the detent pawl to engage the gear. Normally, the Detent FF is set by the trailing edge of the last track pulse during a seek. It is also set when the disks are not up to speed and the carriage velocity is less than 2 ips. This prevents head scoring.

Upon receipt of any seek command, the FF clears. This completes the AND gate into card L201. Turning on the card applies a high current through coil L210 to quickly pull the pawl away from the gear teeth. After 2 ms, the Y312 term into card L201 goes to zero. Card L200 then controls current through coil L210 to hold the detent in its retracted position.

SELECTED DRIVE READY

The selected drive ready signal informs the controller that the heads have reached the addressed cylinder. This -Q level is returned to the controller via T202 10.2 ms after the Detent FF sets. The selected drive ready will be disabled and replaced by the seek incomplete signal, if the selected drive ready signal is not returned to the controller within 600 ms. Seek incomplete is a -Q level sent to the controller via T204. No matter which of the two previously mentioned signals is sent to the controller, it will be accompanied by a -Q level Attention sent via T203.

TRACK CELL

The glass timing disk has 203 slots on its middle ring to indicate cylinder position. As the heads move across the disks, the timing disk rotates. Each time a slot passes the track cell, allowing light to hit the cell, the output on ONA Y244 goes to "0" and Y243 goes to "1". As the cell goes dark the input to I203 from Y244 goes to a "1" after 4 usec. ANDing the outputs of Y244 and I203 provides a 4 usec trailing edge "1" pulse to decrease the decrement counter and partially enable Detent FF. The ONA outputs are also used to partially enable the Stop FF.

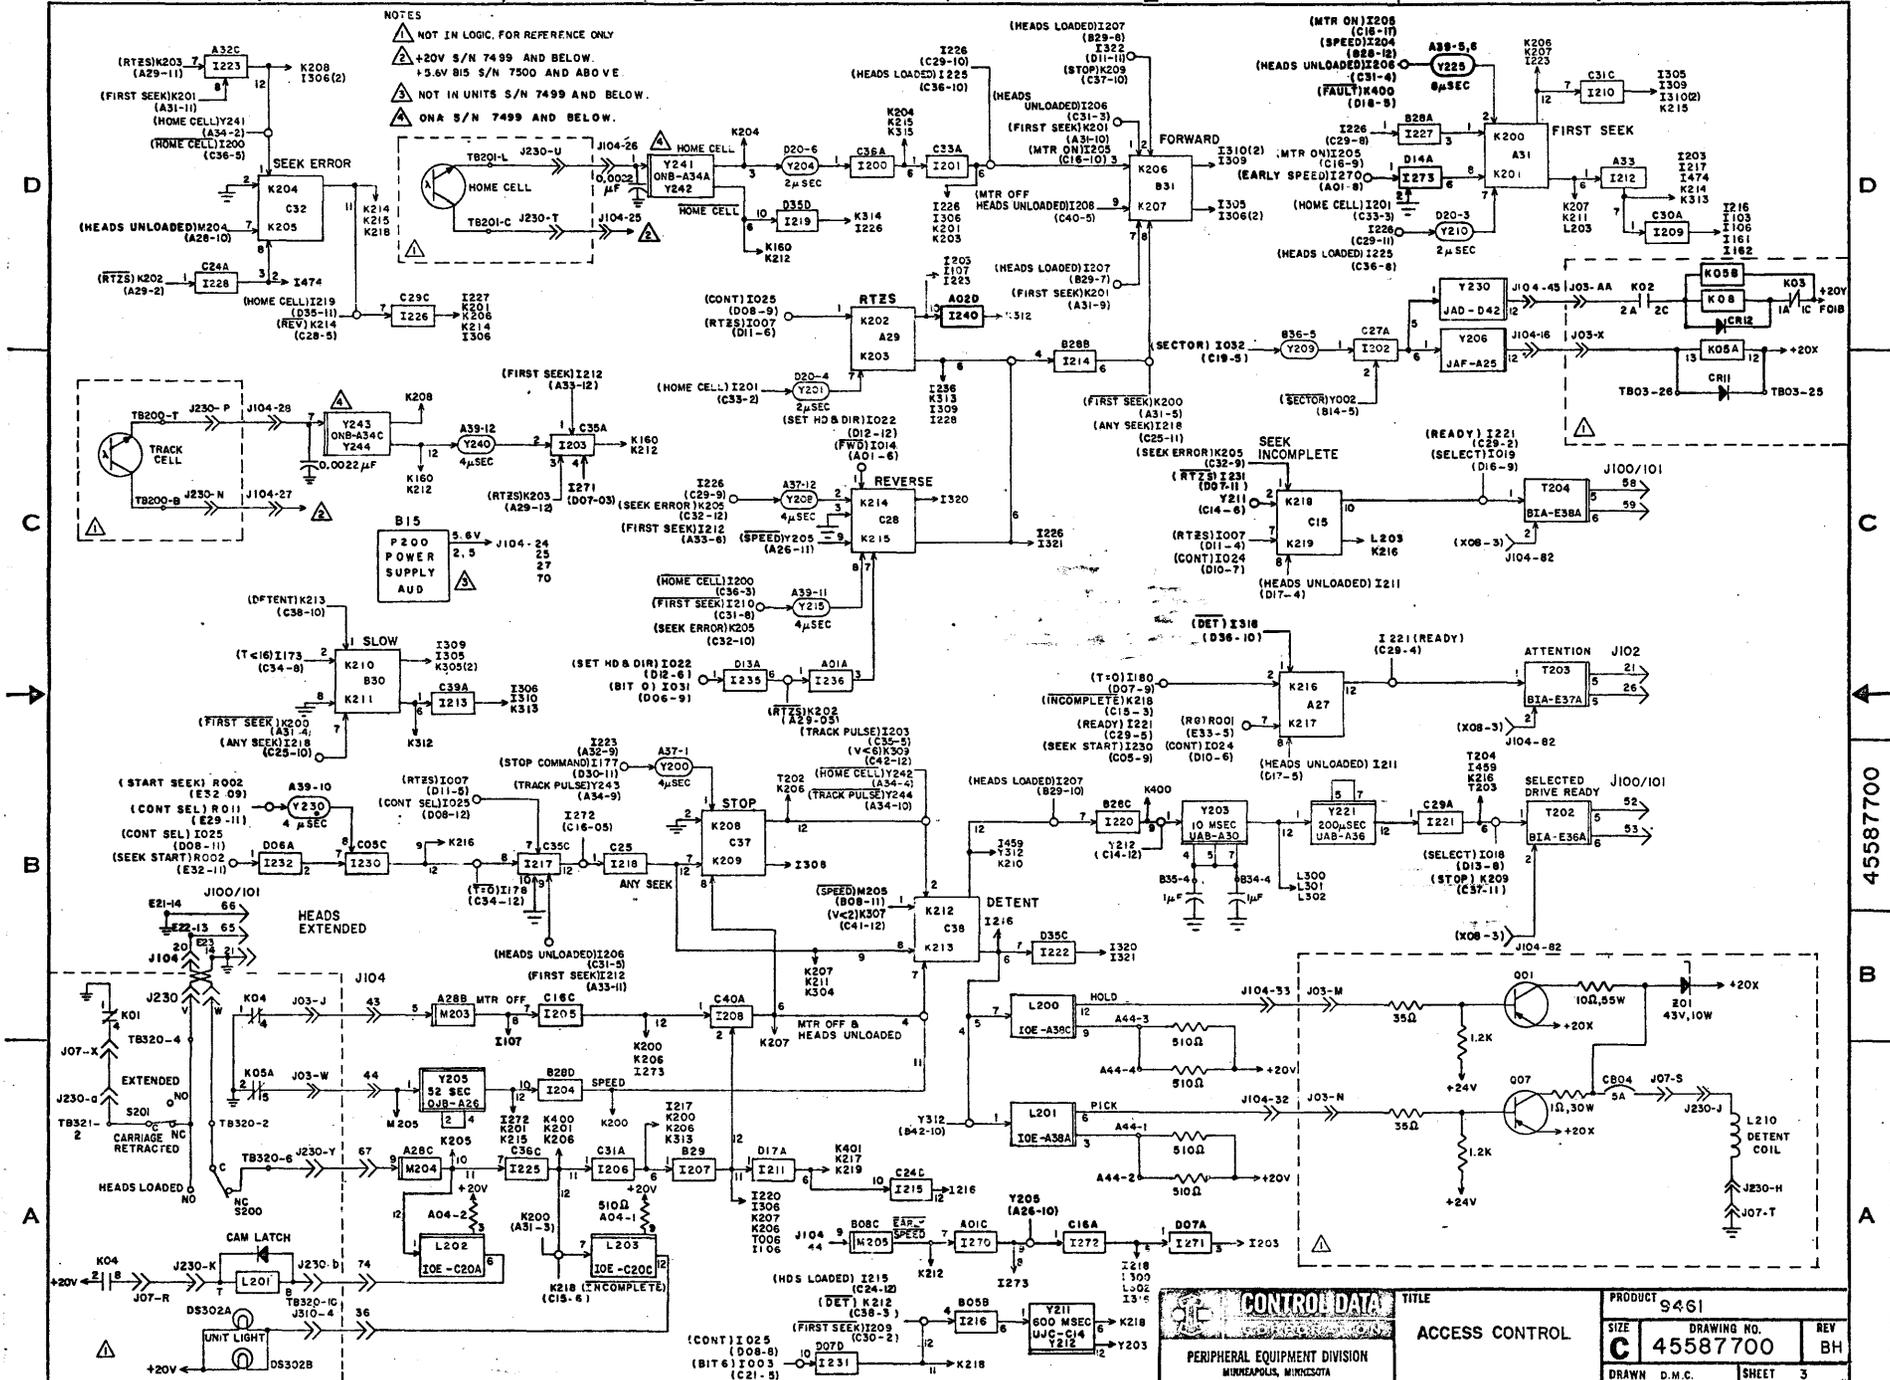

All input/output signals are Q or L levels or pulses. These signals are within the following voltage ranges:
+Q = +3.5 to +0.65 vdc, -Q = -0.5 to -3.5 vdc, +L = +6.28 to +2.0 vdc, and -L = +0.3 to 0.0 vdc.

SPEED CELL

The glass timing disk has slots in its outer ring used to indicate speed of carriage motion. As each slot permits light to hit the speed photocell, the leading edge of the pulse out of ONA Y321/322 is used to initiate a timing chain generator composed of FF's K300/301 and K302/303. The outputs of these FF's are applied to three UAB delay cards: Y305, Y306 and Y307. If the speed is low enough to allow one or more of these delays to time out, their associated inverters will output a "1" to signify head speeds of less than 15 ips, 6 ips, or 2 ips. These outputs are applied to the set inputs of V<2 FF K306/307, V<6 FF K308/309, and V<15 FF K310/311. The outputs of these FF's in turn, are used to control carriage motion.

MOTION

The printed circuit motor which drives the carriage is controlled by an H-switch consisting of Q03 through Q06. The motor drives forward when the AND gate into L300 is made. Operation of the circuit during a forward seek is explained below.

Upon receipt of a forward command, the Forward FF (K206/207) is set; the Detent FF (K212/213) clears to pull the detent pawl. The direction of seek is sensed by I305 and I309; all inputs to I305 must be "0" to drive forward. Since velocity is 0 ips at this time, I305 outputs a "1" and forward motion starts. (I309 in the reverse circuit operates in a similar manner; if all of its inputs are "0" the motor drives in reverse.)

Rate of motor acceleration is controlled by the Not Max Drive FF (K212/213). When the FF is cleared transistor Q02 is turned on to permit high current flow through the access motor's H-switch, this causes maximum acceleration or, in the case where opposing current is enabled, maximum deceleration. When a seek starts where tracks-to-go exceed 4, the FF clears after delay Y312 times out; the delay permits the detent pawl to clear its gear.

Assume a full 199 track seek. The motor accelerates to a full speed of approximately 35 ips until there are less than 64* tracks to go. The output of I305 goes to "0" when T (tracks-to-go) is less than 64 and V (carriage velocity) is greater than 15 ips. At the same time, the "1" input to I310 in the reverse drive circuit causes opposing current to flow through the H-switch. The motor is then rapidly braked to 15 ips. When V is less than 15, the Not Max Drive FF sets to turn off high current. The 15 ips speed is maintained by serving the motor; I305 and I310 alternately output "1's" and "0's" to maintain a constant speed.

When tracks-to-go are less than 16, the slow FF sets. The Per Dy Brk (Permit Dynamic Braking) FF (which was set at the start of the seek) enables the AND gate input to I310 to again apply reverse current. At the same time, Not Max Drive FF is again cleared. Therefore, the motor is rapidly slowed to 6 ips. When the speed is less than 6 ips, Not Max Drive FF sets, while Per Dy Brake FF clears. Speed is maintained in a "hit and coast" manner. That is, I305 turns on the motor when speed is less than 6 ips, then turns it off when speed exceeds 6 ips.

*Less than 80 tracks to go for units with serial no.980 and below not having FCO 1846 installed.

When tracks-to-go are less than 4, I311 sets K304/305. The motor is again dynamically braked until speed is less than 2 ips. Note that the braking action is now low current since the Not Max Drive FF remains set. Speed of 2 ips is maintained in a hit and coast manner.

The trailing edge of the next to last track pulse causes a stop command which combines with the leading edge of the last pulse to set the Stop FF.

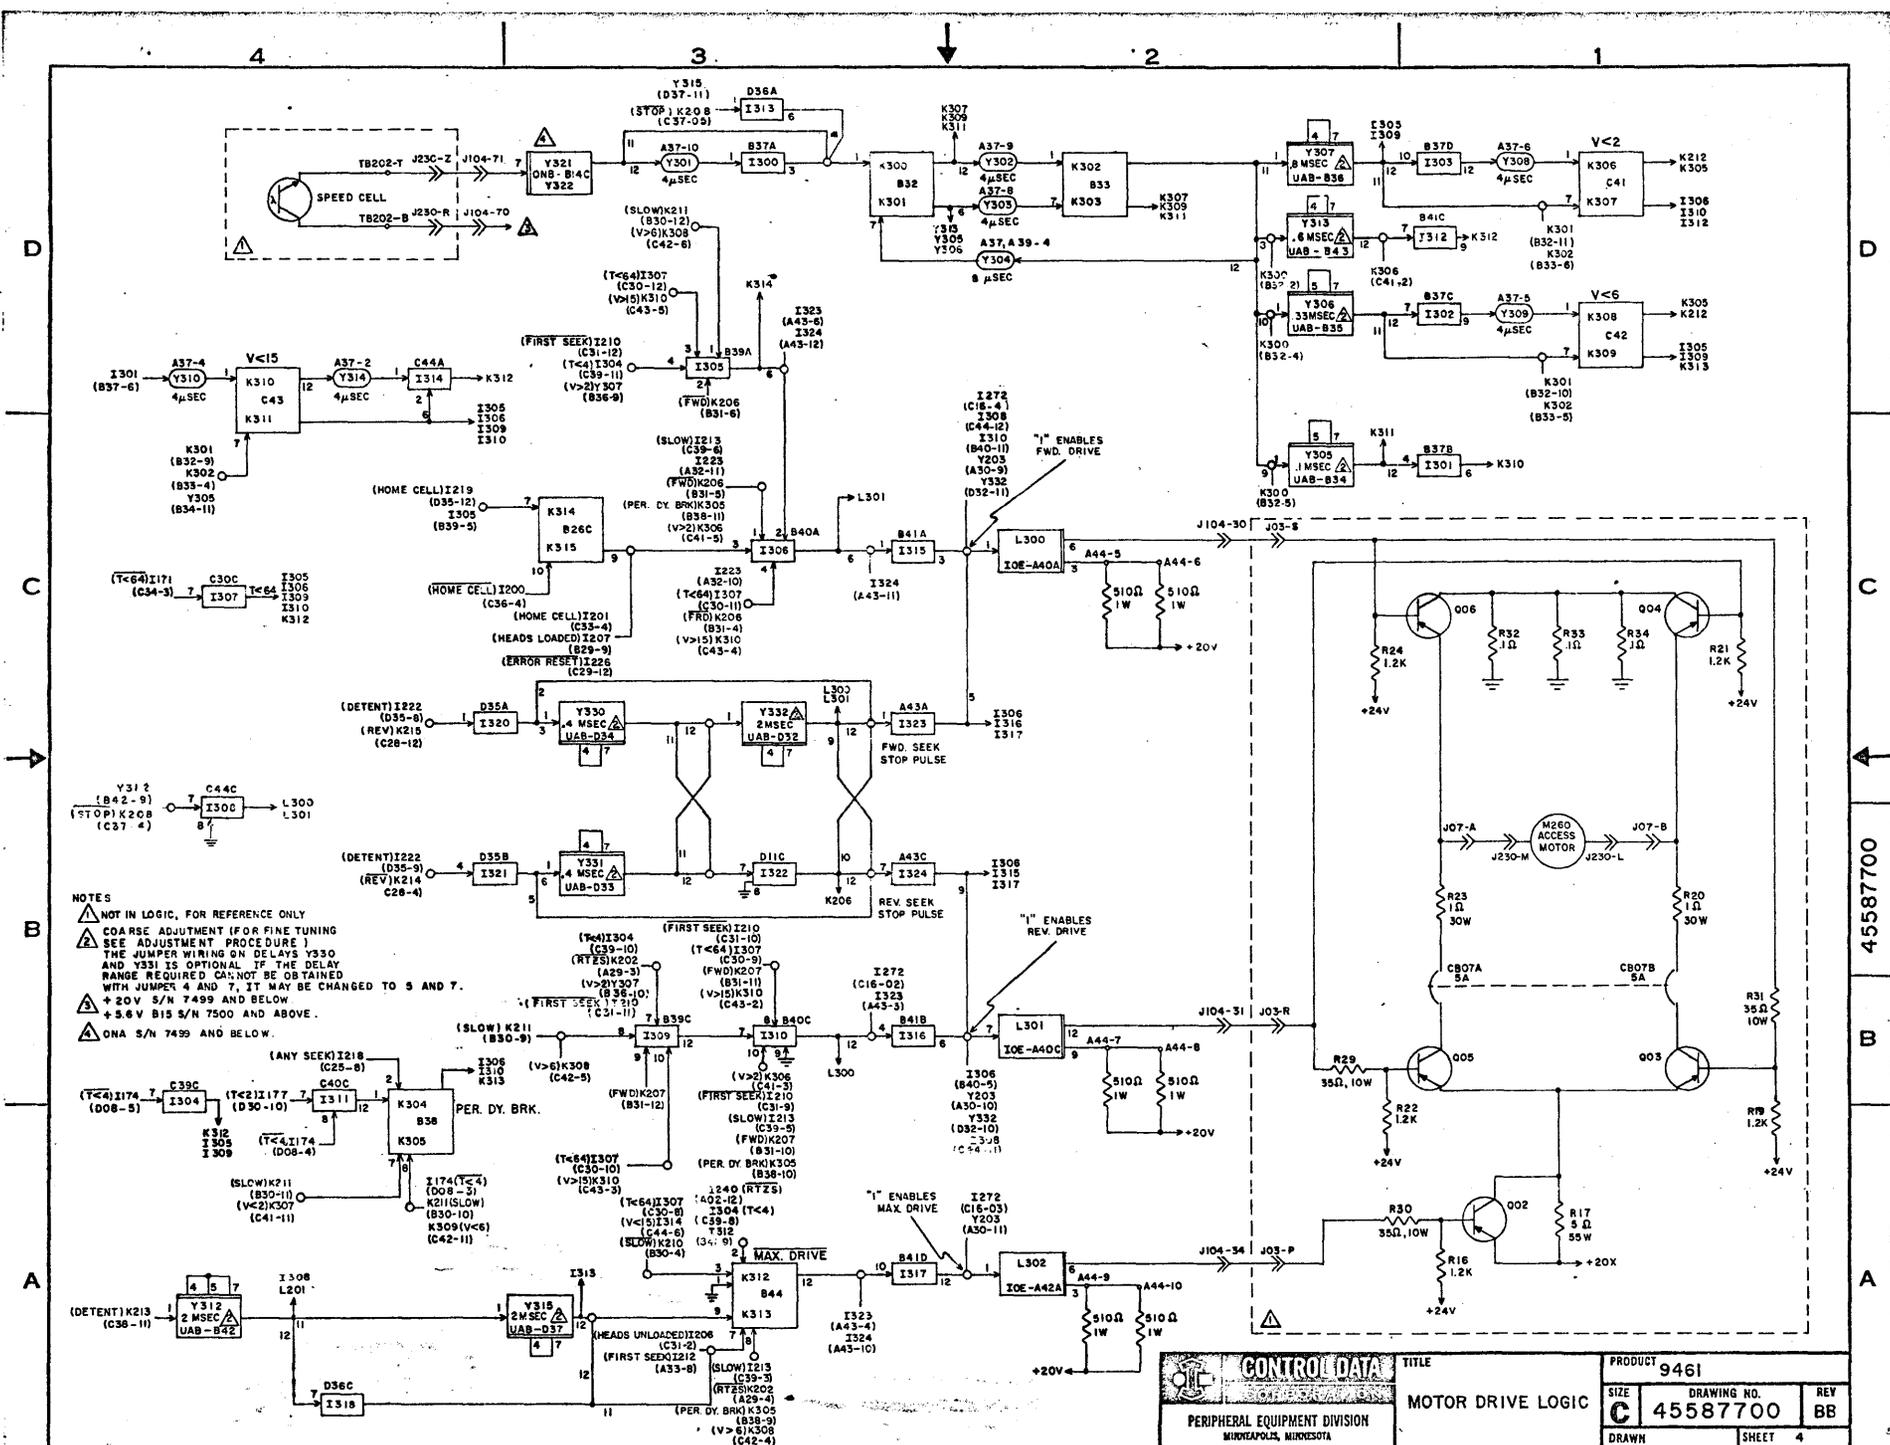

Detent FF sets on the trailing edge of the last track pulse. The circuit consisting of I320 through I324, and delays Y330 through Y332 provide a motor stop pulse. In a forward seek, after the Detent FF sets, a 2 ms "0" pulse delayed by Y331 from I323 is applied through inverters to cards L301 and L302 to stop the motor by the time the detent pawl meshes with its gear.

Operation of this circuit during a return to zero seek is as follows:

1. With RTZS FF set and Forward FF cleared, reverse drive is supplied by the "1" output of I309. Acceleration is retarded since Not Max Drive FF is set.
2. Speed is maintained in a hit and coast manner at 6 ips by the V greater than 6 term that is applied to I309.
3. When the home cell lights, the RTZS FF clears and Forward FF sets. The output of FF K314/315 forces forward drive back to cylinder 00.

FAULT

The Fault FF K400/401 is set if one of the following malfunctions occurs:

1. More than one head selected.
2. Write current OR non-complement write current AND no erase current.
3. Erase current AND no write current OR no non-complement write current (if condition exists for more than 200 usec).
4. Read, Write, OR Erase Gate AND no Selected Drive Ready.
5. Write Gate OR Erase Gate AND Read Gate.
6. Write Gate AND no ac write current.
7. Low voltage condition on disk storage ± 20 vdc or + 36 vdc outputs.
8. Loss of ac line voltage (from controller) to disk storage drive.

One or more of the above conditions will:

1. Generate a -Q level Drive Unsafe signal.
2. Remove all write and erase current from the heads.
3. Disable the Set Head and Direction tag.
4. Set all Q-level type output cards (except Drive Unsafe and Selected Module) to the +Q level.
5. Light the SELECT LOCK switch/indicator.

All input/output signals are Q or L levels or pulses, these signals are within the following voltage ranges:
 +Q = +3.5 to +0.65 vdc, -Q = -0.5 to -3.5 vdc, +L = +6.28 to +2.0 vdc, and -L = +0.3 to 0.0 vdc.

HEAD ADDRESS REGISTER

The head address register consists of FF A400/401 through A416/417. The output of the register is applied to the 10 head select cards (G40-) to control which head will read, write, or erase.

The register may be set in two ways. One method is by means of the Set Head and Direction line. When this line is up, the address and control bus directly sets up the register to select the desired head.

If it is desired to select the heads sequentially on a cylinder the Control Select line and bit 3 of the address bus is used to initially set the register to zero. Thereafter, a head advance signal may be applied to I473 to increment the register to the next head.

In either method, the timing pulse generator consisting of FF K402/403 and K404/405 provides the enabling pulses to transfer the count in rank I to rank II of the register.

READ CHAIN

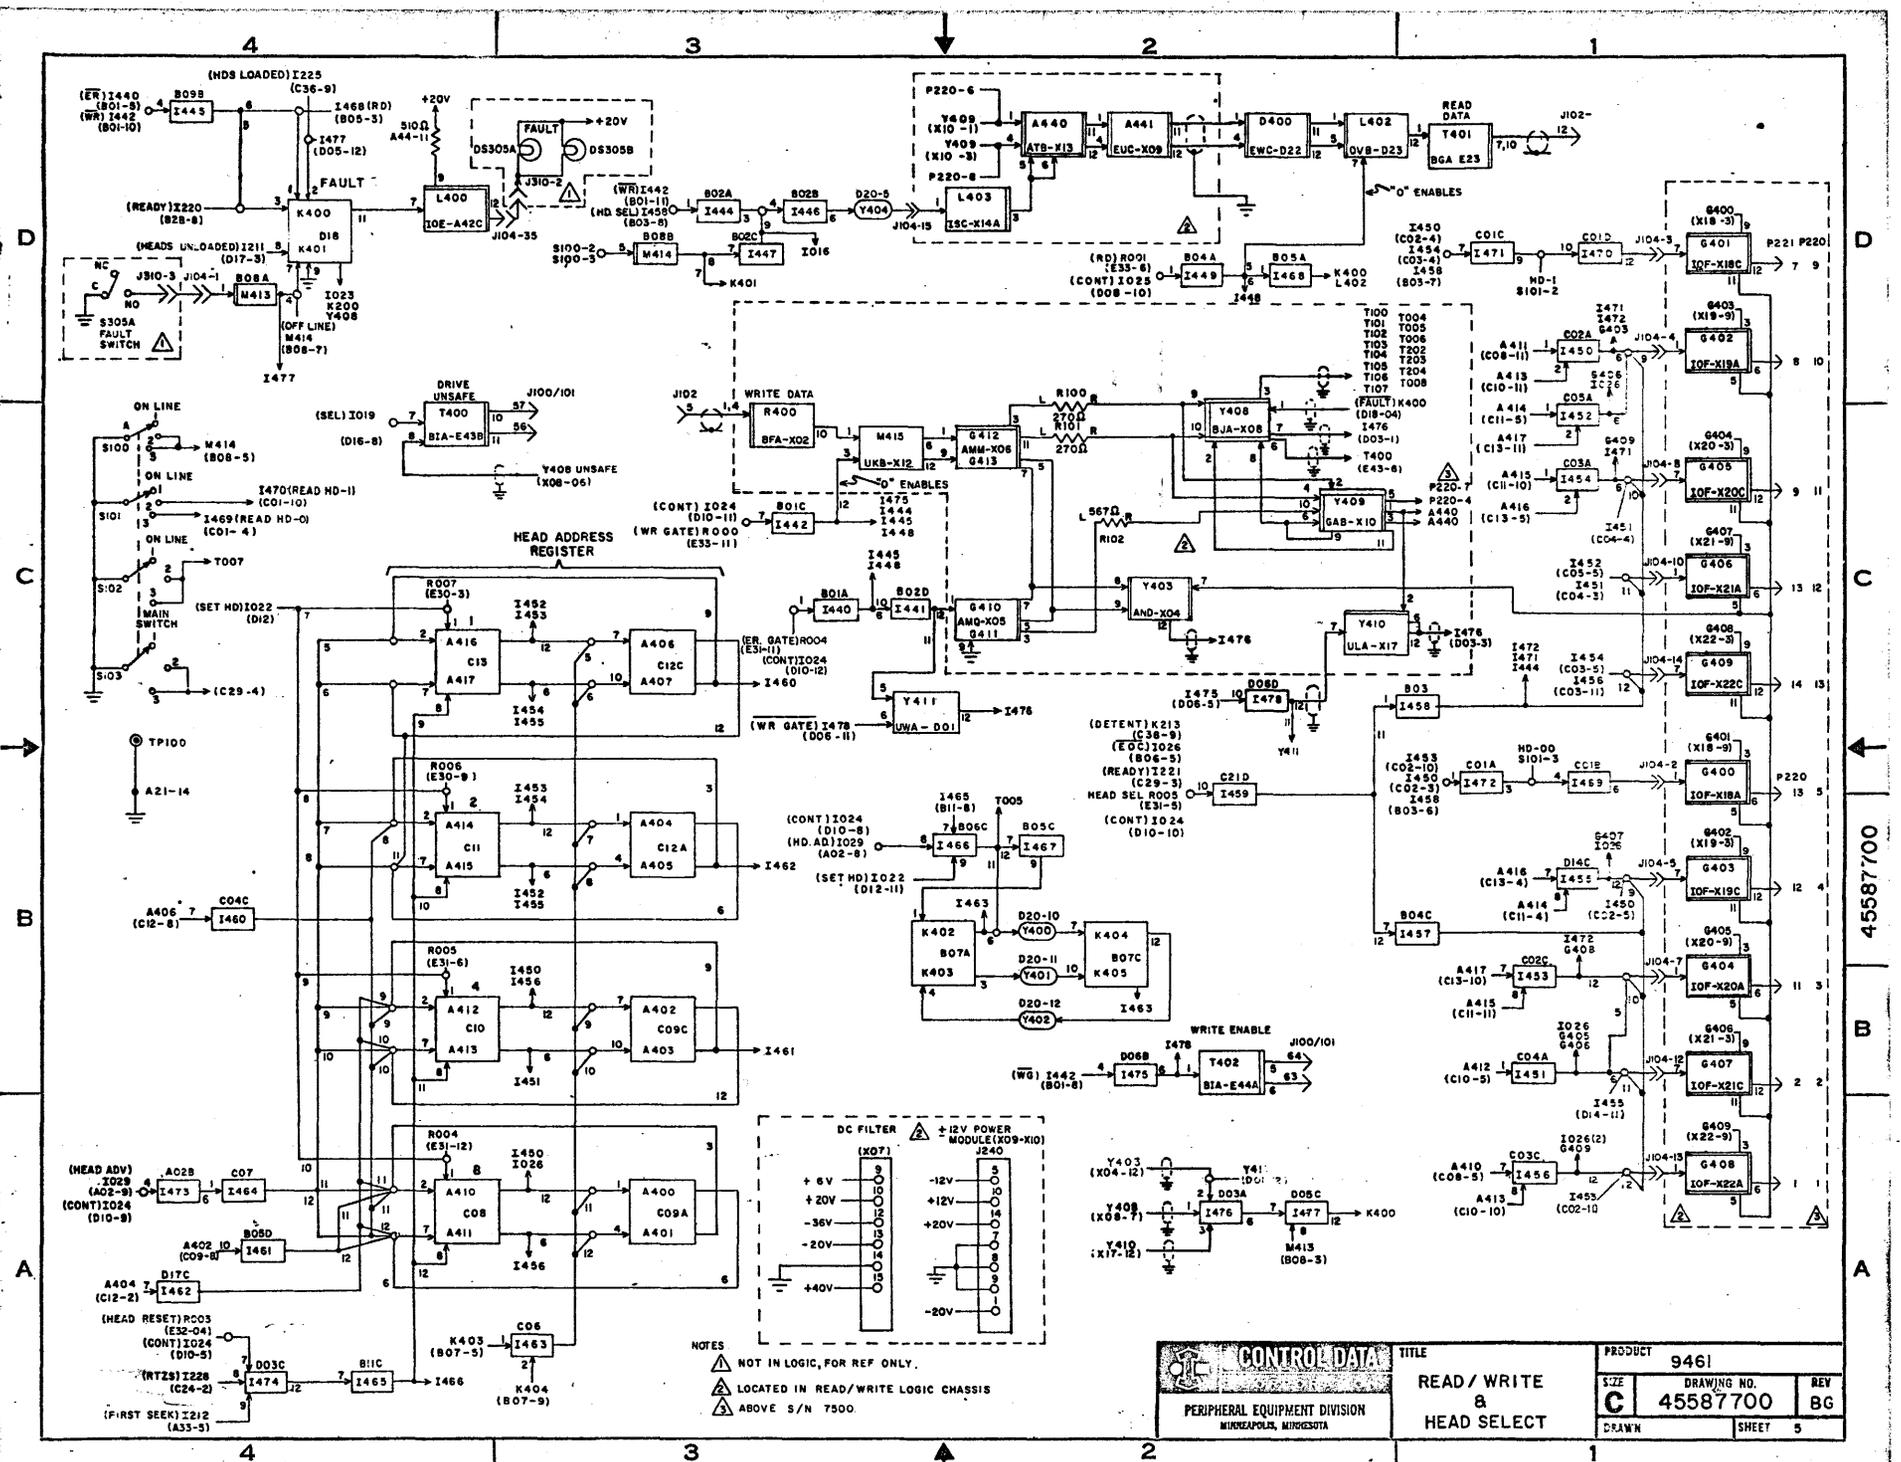

The read chain consists of cards A440, A441, D400, L402, and T401. The analog output of the selected head is applied to the ATB gated read amplifier, then amplified by the EUC differential amplifier A441. Shaper D400 converts the analog input from the heads to a square wave output. If the read mode has been selected, the OVA pulse shaper gates the square wave output to T401 for transmission to the controller in the form of +L pulses.

WRITE CHAIN

Erase enable is applied to AM- erase driver G410/411 via I440 and I441. In order to write, a write enable must be applied through I442 to UKB toggle M415. Write information, in the form of -L level data pulses, is applied to UKB toggle M415 via R400. The UKB switches state at the leading edge of each write data pulse; its output is applied to AMG G412/413. Write current is then allowed to flow through the head selected by the head address register. Outputs of both AM-drivers are applied to AND card Y403 to check for any unbalance of the output voltages. (If there is an unbalance, Y403 sets the Fault FF K400/401.)

GENERAL

The power supply is completely solid state to provide low dissipation and high reliability to the operating system. The power supply provides an adjustable ± 20 vdc to the logic chassis, +24 vdc and +20X vdc to the access motor and detent solenoid, +20Y vdc and +36 vdc to the power sequencing circuit, +40 vdc to the Write circuit and dynamic braking circuit, and 24 vac to the brush motor circuit.

The main power supply is supplemented by an auxiliary power unit which provides +5.7 vdc for the fiber optic source lamp.

These voltages are sequenced and coupled to the related circuit in such a way as to prevent improper head loading, track accessing, or disk movement.

DC POWER CIRCUIT

The 208-volt input power is applied through the closed contacts of the MAIN POWER circuit breakers to the line voltage indicators, to the fan motors, and to the primary windings of ferroresonant transformer T01.

Since T01 is a ferroresonant transformer, the voltage developed in the secondary windings tend to remain constant, regardless of the voltage variation of the applied signal or the load applied to the secondary. The voltage developed across the secondary of T01 is coupled from pins 8 and 9 to the primary of transformer T02 and rectifier diodes CR01, CR02, and CR04. Also coupled from pin 8 is 24 vac which is supplied to the brush motor circuit.

Rectifier diodes CR04A and CR04B, and rectifier diodes CR01A and CR02A develop +20 vdc and -20 vdc, respectively, at their junctions. Capacitors C01 through C04 and chokes L01 and L02 filter the voltages before they are supplied to the logic chassis. Rheostats R03 and R04 are used to adjust the voltages to their proper levels. R01 and R02 are bleeder resistors.

The voltage applied to the primary windings of transformer T02 is coupled to the secondary. The secondary voltage is applied to rectifier diodes CR03A and CR03B which develop +40 vdc at their junction. Capacitor C07 filters the voltage before it is applied through relay K05B to the read/write/erase circuit in the logic chassis. Also developed at the junction of CR03A and CR03B is +40X vdc which is applied to resistors R08 and R25.

Resistors R07 and R08 and resistors R25 and R41 form voltage dividers. The +20Y vdc developed at diodes CR01B and CR02B is applied to resistors R07 and R41. The junction of resistors R07 and R08 is driven to +24 vdc which is applied to the H switch and detent circuits. Resistors R25 and R41 develop +36 vdc at their junction for power sequencing.

The +20Y volts is also applied to filter capacitors C09, C10, and C11. Resistor R06 is a bleeder to discharge the capacitors once the unit has been turned off. The filtered +20Y vdc is used for power sequencing.

FIBER OPTICS POWER SUPPLY

The secondary voltage of transformer T01 is coupled from pins 5 and 7 to rectifier diodes CR01A and CR01B in the fiber optics power supply. Rectifier diodes CR01A and CR01B develop +5.7 vdc at their junction and apply the voltage to filter capacitors C01 and C02 and filter choke L01. The filtered voltage is coupled through rheostat R03 to the photocell lamp. Resistor R01 is a bleeder to discharge the capacitors once the unit has been turned off.

POWER-ON SEQUENCE

Sequencing of power within the power supply is accomplished by seven relays. This sequencing is necessary to prevent damage to the heads and/or disks and to ensure proper control of the actuator mechanism by the logic.

Motor sequence relay K01 is energized when the unit receives a sequence in from either the control unit or the previous storage drive on the line. If the disk drive unit START switch is not lighted (S301 set to OFF), the sequence out level is applied to the next storage drive. This sequencing of the storage drives is necessary to prevent loading of the primary power source.

Assume that a Power-On command is received from the control unit and the START switch (S301) is lighted. The +36 vdc is applied through connector J03 to complete the path and energize relay K01. When relay K01 is energized, contacts 1 and 7 close to energize relay K02. When K02 is energized, contacts 3A and 3C close to supply +20 vdc to the logic chassis, and contacts 4C and 4A close to supply -20 vdc to the logic chassis.

Relay K01 also completes the path through contacts 3

and 9 to energize relay K04 (assuming the disk pack is on, both top covers are closed, and the START switch is lighted). Contacts 2 and 5 of K04 open and remove +20Y volts to the brake solenoid, L300. This causes the pawl to free the spindle and close the spindle interlock switch, S333. Contacts 2 and 8 of K04 close to provide +20X to the sector solenoid, L301. The solenoid energizes, swinging the sector sensor assembly into the disk pack, thus closing the pack cover on switch, S334.

With switches S333 and S334 closed, a path is completed to energize relay K03. K03 contacts 2A/2C, 3A/3C, and 4A/4C close to apply power to the spindle motor, M360. K04 contacts 1 and 4 open and apply an output signal, indicating that the motor is on. Contacts 1A and 1C of K03 close so that power will be applied to the head latch solenoid (L200) and the cam latch solenoid (L201) when the disk pack is up to speed.

At 80 percent of the rated speed, the logic completes a circuit to energize relay K05A through J03-X. When this relay energizes contacts 1 and 4 open and a signal is applied to the logic, indicating that the pack is up to speed. This signal is applied to a 52-second delay card which allows time for the air to be purged from the disk pack area before loading the heads and for the brush assembly to complete a clean cycle of the disk pack.

Contacts 1 and 7 of K05A close to provide +40 vdc to the Write circuit and contacts 2 and 8 close to apply power to the head latch (L200). Once the heads are loaded, the solenoid armature holds the heads loaded.

POWER-OFF SEQUENCE

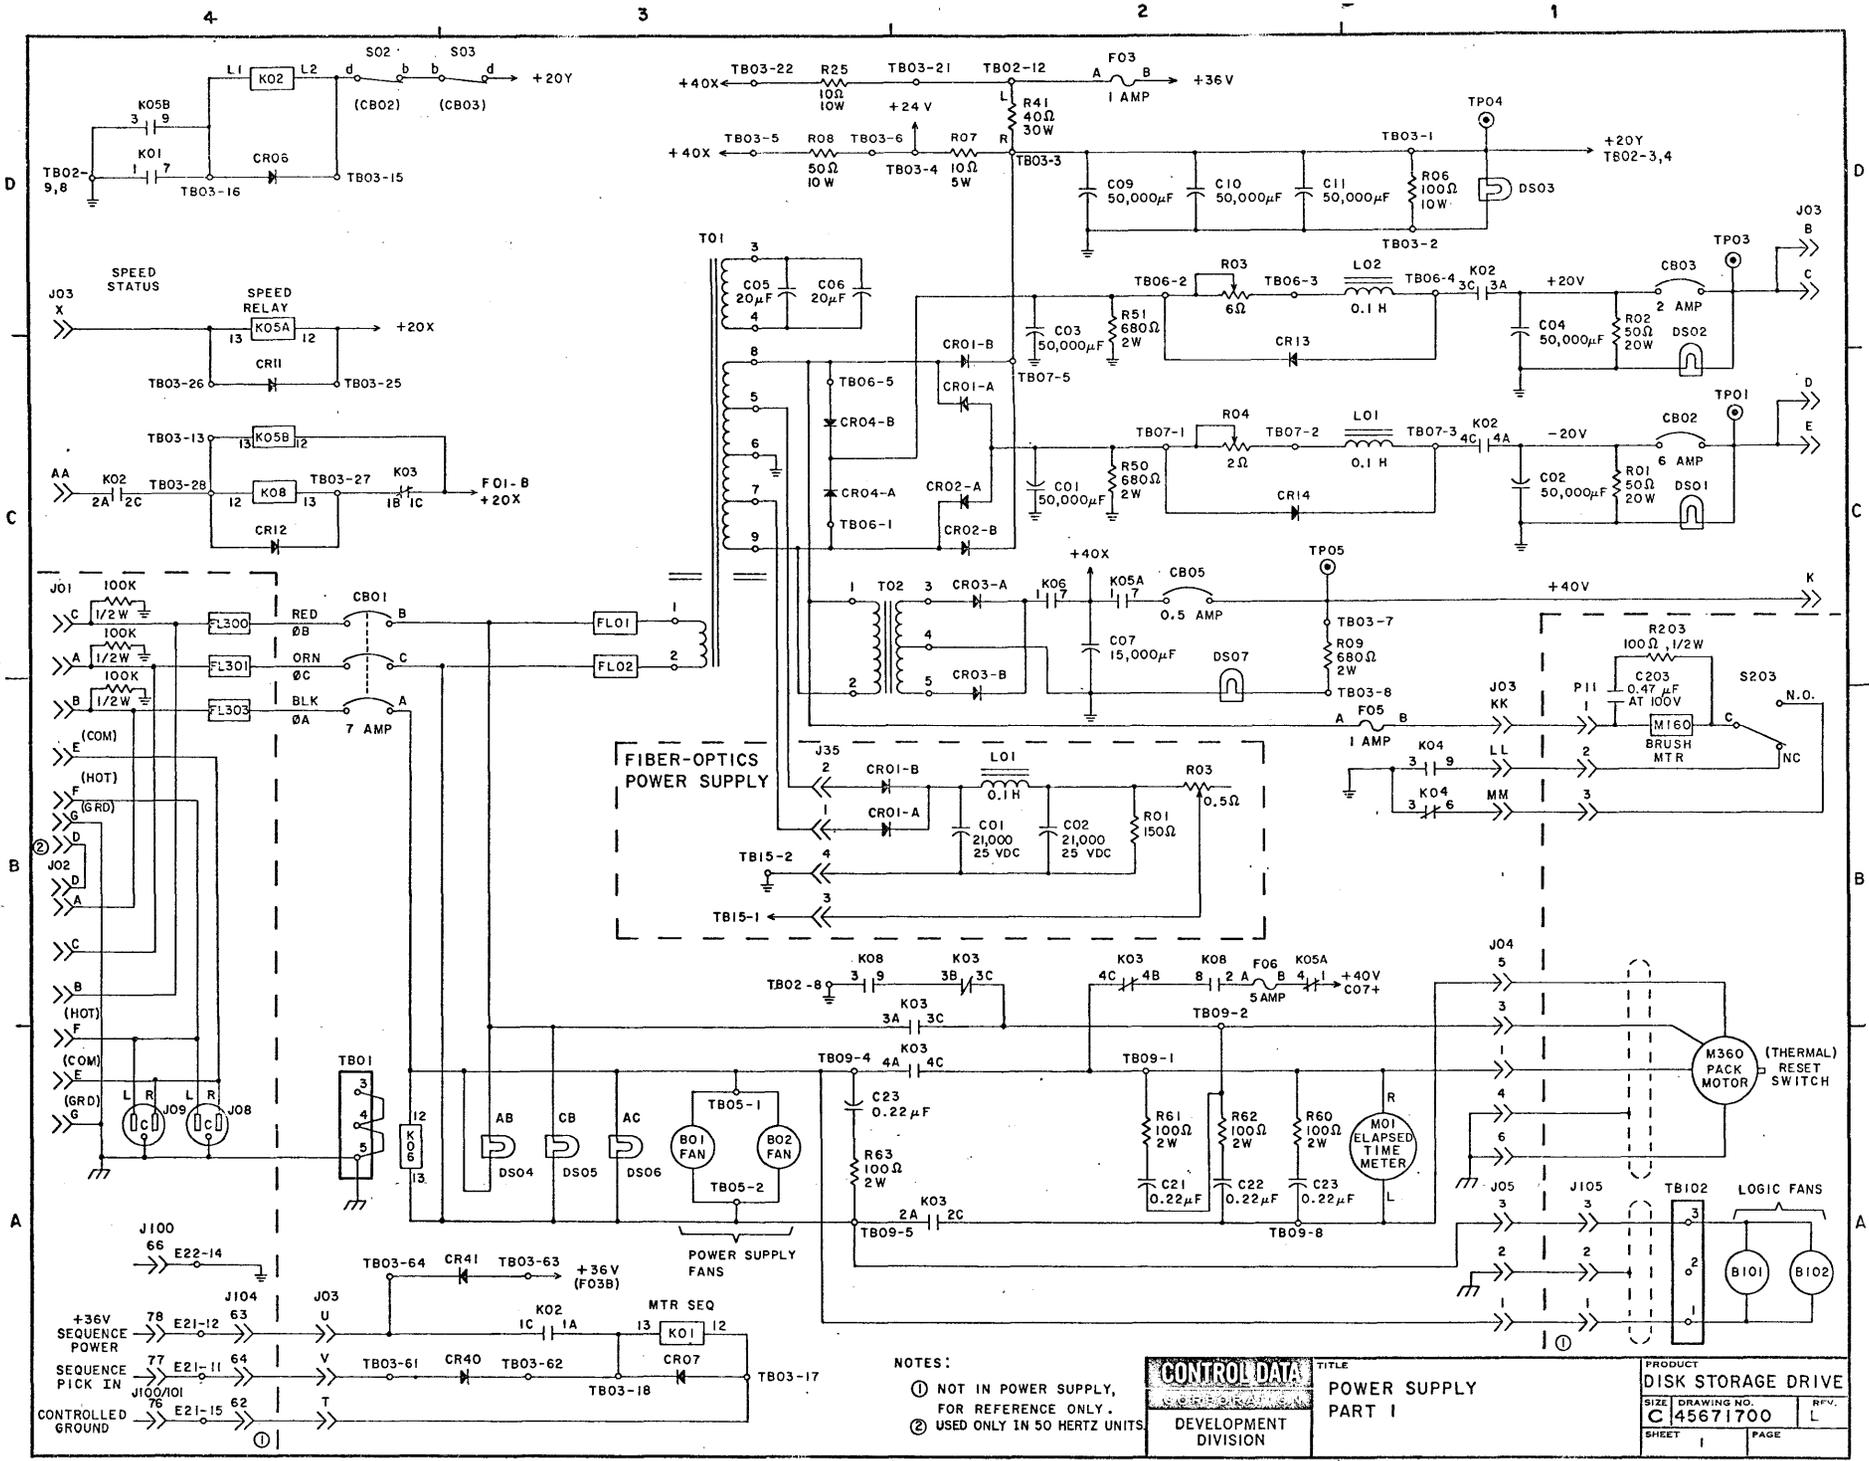

Power in the disk storage drive can be cycled off in any of three ways: from the START switch on the disk storage drive operator control panel, by opening either top cover, or from the control unit. It is assumed that the purpose for this Power-Off sequence is to change packs. The sequence is initiated when START switch S301 is pressed, opening the contacts of S301A and breaking the circuit that holds relays K03 and K04 energized. The following events occur:

1. K03 contacts 2A/2C, 3A/3C, and 4A/4C open and remove power to the spindle motor, M360 (rotation begins to slow).

REV E

NOTES:
 ① NOT IN POWER SUPPLY, FOR REFERENCE ONLY.
 ② USED ONLY IN 50 HERTZ UNITS.

CONTROL DATA <small>AN INSTRUMENT DIVISION</small>	TITLE	PRODUCT
	POWER SUPPLY PART I	DISK STORAGE DRIVE
	DEVELOPMENT DIVISION	SIZE DRAWING NO. C 45671700
		REV. L
		SHEET 1 PAGE

Power-Off Sequence (cont'd)

2. K03 contacts 3B/3C and 4B/4C close (partially completes circuit that will later dynamically brake the spindle motor).
3. K04 contacts 1 and 4 close and signal logic that the spindle motor is off.
4. K04 contacts 2 and 5 close (partially complete circuit that will energize the brake solenoid when spindle motor speed is less than 50 rpm).
5. K03 contacts 1A and 1C open to remove power to the head latch (L200) and cam latch (L201) solenoids (heads unload and carriage starts retracting).
6. K03 contacts 1B and 1C close to energize relay K08.

Energizing K08 closes contacts 2/8 and +40 vdc is applied to the windings of the spindle drive motor. This causes a magnetic field to form. The field opposes further rotation and the motor speed slows rapidly (dynamic braking).

When the logic senses the spindle motor speed is less than 50 rpm it de-energizes relay K05B. This causes the following events:

1. K05B contacts 2 and 8 open to remove the +20X voltage to the sector solenoid. (L301) and the access motor H switch (prevents further movement of the carriage).
2. Contacts 3 and 6 close to energize the brake solenoid (L300) so that the pawl on the spindle lock assembly engages the spindle lock disk to hold the spindle stationary.
3. Contacts 3 and 9 open, de-energizing relay K02.

When relay K02 de-energizes, contacts 3A/3C and 4A/4C open, removing +20 vdc to the logic chassis.

DETECT CIRCUIT

Upon receipt of any seek command, transistors Q01 and Q07 are forward biased and the transistors are gated on. When the transistors are gated on a high current pulse is applied through the detent coil L210 which quickly pulls the detent pawl away from the gear teeth. After approximately 2 msec transistor Q07 is gated off. Transistor Q01 remains gated on to provide holding current for the detent coil until a detent command is received.

The holding current flows through resistor R13, reducing the current to approximately 2 amps. When the detent command is received, power is removed from the base of Q01 and current flow is stopped. In approximately 2 msec the spring-loaded pawl is pulled into and engages the detent gear.

PRINTED CIRCUIT MOTOR MOTION CONTROL

The printed circuit motor, which moves the carriage drive and positioning mechanism, is controlled by a 5-transistor switching circuit. By controlling the transistor selection and the amount of current through these transistors, the motor is driven fast or slow in the reverse or forward direction. Transistors Q03 and Q06 are switched on for a forward operation, causing the printed circuit motor to drive the carriage forward. Transistors Q04 and Q05 are switched on for a reverse operation, connecting the switching circuit in such a manner as to allow motor current flow in the reverse direction.

The five transistors (Q02 through Q06) are normally gated off by the +24 volts applied through resistors to each base. Emitter voltage, applied to the PNP transistors, is supplied by the +20X voltage source. The base bias voltage is greater than the applied emitter voltage to assure that the transistors are cut off when not selected. When a move command is applied, the base resistors complete a voltage divider resulting in a forward-biased transistor.

Resistors R29 and R31 prevent overdrive of transistors Q03 and Q05 respectively. This allows the amplifier card inputs to the switching circuit to drive both switching transistors (Q05 and Q04, or Q03 and Q06) in parallel, even though the emitter reference voltages are different. The values of R29 and R31 are selected to provide equal drive to the parallel-switching transistors.

The magnitude of current in the printed circuit drive motor is determined by the power supply voltage and the total effective series resistance in the circuit. The voltage supplied to the switching transistors is fixed, but the total circuit resistance during the high current drive, excluding the saturation resistance of the switching transistors, is approximately 2.5 ohms. After the current is reduced, the total circuit resistance is approximately 12.5 ohms.

The use of series resistor R17 during slow speeds prevents excessive current and motor torque when

not needed. Slow speeds are maintained by servoing and not current limiting. Circuit breaker CB07 prevents sustained high-level currents from damaging the printed circuit motor.

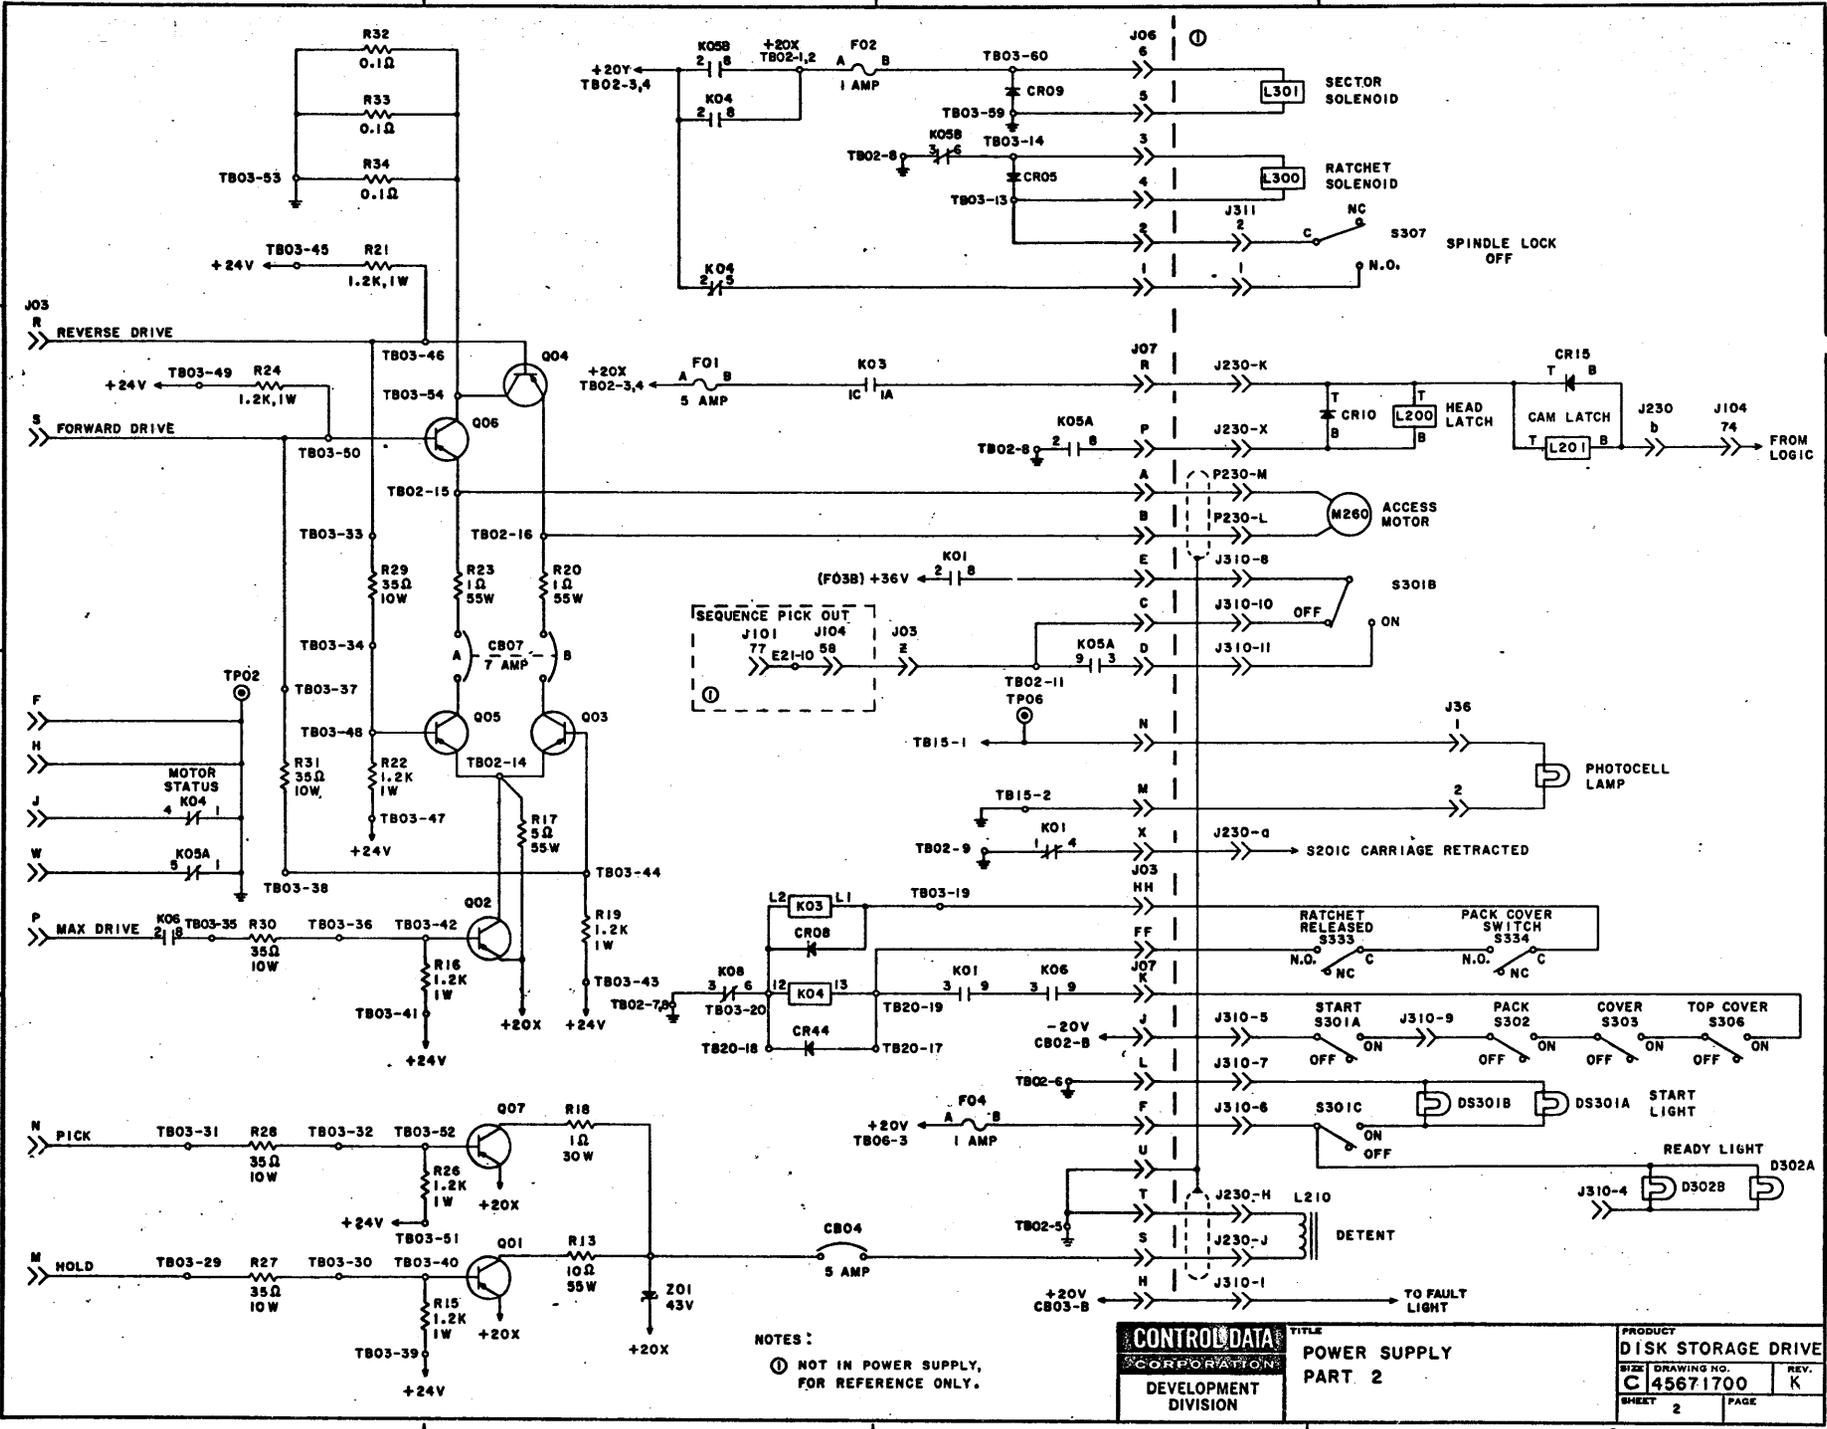

Assume that a forward move command of greater than 64 tracks is received; ground is applied through pins P and S of power supply jack J03 to bias on the respective transistors. The Fast command or ground level applied to J03-P turns on Q02. The ground level applied through J03-S forward biases Q06 and Q03. Electron flow is through parallel resistors R32, R33, and R34, through forward biased transistor Q06 to the one side of the printed circuit motor. From the motor, electron flow is through resistor R20, forward biased Q03, and forward biased Q02 to +20X vdc. With electron flow through Q03 and Q06, the motor is driven forward. Transistor Q02 shunts resistor R17, resulting in maximum current flow through the motor and consequently maximum motor acceleration. When the Decrement counter indicates less than 64 tracks remaining, and if the carriage velocity is greater than 15 inches per second, the following occurs:

1. Q03 and Q06 are switched off and Q04 and Q05 are switched on (Q02 remains on). The reverse current through the motor causes the motor to slow the carriage down.
2. When the carriage speed has slowed to 15 inches per second in the forward direction, Q02, Q04, and Q05 are turned off.
3. From this time until the Decrement counter indicates less than 16 tracks remaining, current pulses through the H switch are used to sustain 15 inches per-second carriage speed.
4. With 15 tracks remaining, Q02, Q04, and Q05 turn on (Q03 and Q06 turn off), and again the motor is used as a brake, slowing the carriage to 6 inches per second.
5. At 6 inches per second, Q02, Q04, and Q05 turn off and current pulses (through R17, Q03, the motor, and Q06) sustain a carriage velocity of 6 inches per second.
6. With 3 tracks remaining, Q02, Q04, and Q05 turn on and Q03 and Q06 turn off and slow the carriage to 2 inches per second.
7. At 2 inches per second, Q02, Q04, and Q05 turn off and current pulses (through R17, Q03, the motor, and Q06) sustain a carriage velocity of 2 inches per second.

When the selected track is reached, the spring-loaded pawl is dropped.

CARD PLACEMENT

Card Placement information
for the 9461 will be found
on Page 1-11 in this manual.

PART 3

WIRE LISTS

DESCRIPTION OF WIRE LISTS

The two types of wire lists are:

1. The line printer format which shows logic wiring.
2. The corporate (typed) form which shows non-logic wiring.

LOGIC WIRE LISTS

The following is an example of the logic wire lists with an identification, and an explanation of the columns.

Wire Identification	Wire Length	Wire Origin Location	Wire Origin Pin Number	Component Code	Wire Destination Location	Wire Destination Pin Number	Twisted Pair	Wire Size	Color Code	Change Order
K10310	06	A18	07	O	B11	04				
K10311	05	B11	04	O	B20	05				
K10312	03	B20	05	O	B22	06				
K10320	04	A18	08	O	A13	11				
600300	21	J104	33	X	A38	12	20	4	0970	
600310	25	J104	34	X	A42	06	20	4	0970	
600320	25	J104	35	X	A42	12	20	4	0970	
600330	58	J104	36	X	A28	09	20	4	0970	
600340	15	J104	37	X	SHIELD		E	5	0970	
600350	15	J104	38	X	A02	01	24	E	0	0970

Wire Identification

If the first term in this column begins with a letter, the wire originates at a logic card; the letter and the first three digits represents the logic symbol of that card. If the first term begins with a numeral, the wire originates at a point other than logic, for

example at a switch or resistor. A sequential advance in the second to the last digit indicates additional inputs to the same card.

A sequential advance in the last digit indicates the interconnections of an AND input.

K10310	}	Three input AND to K103
K10311		
K10312		
K10320	-	Single input OR to K103

Wire Length

This column gives the wire length in inches.

Wire Origin Location

This column locates the origin of the wire on the logic chassis. Wires having a common signal at two or more locations are interconnected in series. In the sample, the first three wires shown have a common signal. The Wire Destination Location of the first wire becomes the Wire Origin Location of the second so that the series string is from A18 to B11 to B20 to B22. Note that the first four characters of the Wire Identification terms are the same for the three wires and that the sequencing is from 10 to 11 to 12 in the last two characters.

Wire Origin Pin Number

This column identifies the origin pin or terminal of the wire.

Component Code

This column identifies the components that are located in the Wire Origin Location column. The code letters are identified as follows:

- 0 - Logic Card
- R - Miscellaneous Component (Switch, Resistor, etc.)
- X - Jack

Wire Destination Location

This column locates the destination of the wire on the logic chassis.

Wire Destination Pin Number

This column identifies the destination pin or terminal of the wire.

Wire Size

This column identifies the size (AWG) of the wire.

Twisted Pair

When two successive wires have the same letter in this column, this identifies them as a twisted pair.

Color Code

Solid colored wires are identified by a one digit number in this column. Multicolored wires are identified by a number having two or three digits. Each digit of the number identifies one of the colors. The code numbers are identified as follows:

- | | | | | | |
|-----------|------------|------------|------------|-----------|------------|
| 0 - Black | 2 - Red | 4 - Yellow | 6 - Blue | 8 - Gray | S - Shield |
| 1 - Brown | 3 - Orange | 5 - Green | 7 - Violet | 9 - White | |

Change Order

This column identifies the engineering, field, or publications change order that affected and/or altered that wire.

CONTROL DATA		WIRE LISTING							WL	DOCUMENT NO.	REV.
COMPUTER DIVISION									SHEET	OF	
CONDUCTOR IDENT.	FIND NO.	GAUGE (REF.)	COLOR (REF.)	LENGTH (APPROX)	ORIGIN		ACCESS FIND NO.	DESTINATION		ACCESS FIND NO.	REMARKS
	29	24	993	03	X12	03		X12	09		
21	29	↑	993	03	X13	03		X13	09		
22	29		993	03	X14	03		X14	09		
23	29		993	03	X15	03		X15	09		
24	29		993	03	X16	03		X16	09		

Wire lists other than logic are on a standard corporate form. The remaining columns of the form contain information NOT normally applicable to field usage and therefore are not explained.

The other columns indicate:

- Gauge (Ref) - Size of conductor (AWG)
- Color (Ref) - Color information
- Length (Approx) - Length of conductor in inches
- Origin - Origin point of conductor
- Destination - Destination point of conductor
- Remarks - Useful comments

In multi-digit color codes, the first digit denotes base color and the remaining digits denote tracer colors. The color codes for the non-logic lists are the same as those for logic wiring.

NOTES:

1. A HEXAGON IN THE ACCESS FIND NO. COLUMN INDICATES THAT THE CONDUCTOR IS ONE OF SEVERAL (ALL WITH THE SAME NUMBER IN THE HEXAGON) GOING INTO THE SAME TERMINAL. THE NUMBER IN FRONT OF A HEXAGON IS THE TERMINAL FIND NO.
2. FOR MECH. ASSY PL SEE 45675200. NO ASSEMBLY DRAWING AVAILABLE.
3. INDICATES END OF SHIELD IS FLOATING.
4. PIN AND BUGGIE DESIGNATIONS OMITTED ON DRAWING BECAUSE OF TABULATION OF NUMEROUS MODELS. CONDUCTOR LENGTHS TO BE SAME. ONLY PIN DESTINATIONS WILL BE DIFFERENT. SEE W/L 45463800.
5. USE HEAT SHRINK TO COVER TERMINAL.
