SYMBOLIC ASSEMBLY PROGRAM FOR THE LGP-30 COMPUTER

James N. Orton, Royal McBee Corp.

INTRODUCTION

An essential step in the writing of a program in machine language is the use of a symbolic version of the program for the preparation of the final coding sheets. The arbitrary symbols used for addresses are selected to be appropriate to the problem being solved.

The program described in the following pages relieves the programmer of the work of final translation to numerical addresses; a slight modification of the usual symbolic program with machine language instructions and arbitrary symbolic addresses is entered into the LGP-30 computer. The output is a finished program typed in coding sheet format with numerical addresses (not optimized). As part of the input, absolute addresses or hexadecimal patterns may be entered as required in place of the symbolic program steps. Thus the programmer can readily establish linkages with standard subroutines, and in general, has all the "bells and whistles" of the machine at his disposal. Format control is feasible so that comments on the individual program steps are typed on the final coding sheets. The program as it is assembled is stored in the LGP-30 where it may then be executed or punched out using POOL Program K2-71, the Repositionable Decimal Memory Punch, or 13.2, the Hexadecimal Punch.

Programs in languages similar to the LGP-30 machine language may also be used; for example, a program for 24.0, the Floating Point Interpretive Routine, can be assembled by LGPSAP. Unfortunately, 24.1 cannot be assembled because the program does not handle the 800xmmmm instructions, other than the 800Tmmmm.

SYMBOLIC ASSEMBLY PROGRAM FOR THE LGP-30 COMPUTER

James N. Orton, Royal McBee Corp.

PURPOSE:

To input a symbolic code, translate the symbolic addresses into the numeric form required by the LGP-30, store the translated instructions sequentially starting from a specified memory location, and output the code in both symbolic and standard LGP-30 decimal form.

GENERAL DESCRIPTION:

Input. The input to LGPSAP is a symbolic program with a carriage return after each instruction so that it prints one instruction per line. Each symbolic instruction consists of: (1) a symbolic location, if the instruction is referenced by another, (2) the standard LGP-30 operation code, and (3) the symbolic address for flexowriter input, comments may be written to the right of the instruction if desired.

Preceding the program to be input, two words must be input (either manually or from the tape):

1. The starting location of the program, in decimal. The program is assembled beginning at this location.
2. The "reference address" of the program, in decimal. The "reference address" is equivalent to the "modifier" in the Program Input Routine (10.4). If the program is to be executed after assembly, the "reference address" will generally be the same as the starting location. For preparation of a punched tape, a reference address of 0000 may be desirable. These matters are discussed later.

For assembly, the program tape must be input twice to the assembler. Six-bit input is required. On the first pass, the assembler compiles a table of the symbols used in the program, and another table of the addresses represented by the symbols. On the second pass, the assembler stores and outputs the program, substituting the proper memory addresses for the symbolic addresses. Constants, in either hexadecimal or instruction form, and absolute-address instructions may be input as well as symbolic instructions.

Symbolic Checks During input the assembler makes two symbolic checks as a logical aid to the programmer. It notes (1) the use of "multiply-defined" symbols and (2) the use of "undefined" symbols. These terms will be explained by illustration below.

SPECIFIC DESCRIPTION: SAMPLE INPUT AND OUTPUT

The following sample assembly is illustrative of the principal functions of the assembler. A tape of this assembly is included in the program package. An explanation of these immediately follows:

Note on tape contents: The tape distributed with this program description has information punched in the following order:

1. The basic LGPSAP assembler, "LS";
2. The modified 21.0, "D3";
3. "Sample Assembly" (see top page three)
4. Coding for Assembly Routine (LGPSAP and Decimal), see pages 14-20.

LGP-30 USERS' ORGANIZATION - POOL

SAMPLE ASSEMBLY

Double spacing was used on the second pass.

Flexowriter settings: Margin 6, Tabs 12, 16, 22, 32.

.0000700

Output: First pass. The sample printout following "pl" is the Flexowriter output from the first pass. Output in addition to that from the tape itself will occur only if a multiply-defined symbol or other input error (see below) is detected.

If the Photoreader is used for first-pass input (but first see "Note on use of the Photoreader" below), no printout other than "pl" and the error indications will occur.

Output: Second pass. The printout following "p2" is the Flexowriter output from the second pass. The output, in addition to that from the tape, consists of the standard decimal representation of the program as stored in memory. The symbolic and decimal representations of each instruction appear side by side. In addition identifying characters are printed next to the symbolic address whenever an undefined address symbol is detected (see below). Since format controls are all on the input tape, the Flexowriter, rather than the Photoreader, should be used for second-pass input.

Tape format. Instructions which do not have a symbolic location are input in two words: (a) the command and (b) the address, each of which is followed by a stop code (making 2 stop codes per line of coding). Instructions which have a symbolic location are input in four words: (a) an initial zero-word, (b) the symbolic location, (c) the command, and (d) the address, each of which is followed by a stop code (making 4 stop codes per line of coding). The initial zero-word will thus appear as a stop code; its only function is to indicate that the next word input will be a symbolic location.

Format controls (tabs, carriage returns, etc.) should all be punched on the tape. These are arbitrary, save for the following: if a comment follows the instruction one tab must follow this comment (to clear accumulator bits 26 - 31; only the tab will accomplish this, using 6-bit input on a standard Flexowriter). For the sample assembly above, tabs were included between the location operation address and comments; for the assembly of the program itself (see below) the first two of these were omitted.

Note on use of the Photoreader. The standard reader does not input 000000 (6-bit) on the execution of a tab, as required by the assembler if there are any comments included in the program. A minor modification of the input circuitry or exclusion of program comments is thus required for use of the Photoreader on the first assembling pass.

End-of-program symbol. The symbol "end," preceded by one and followed by two stop codes, must follow the last instruction of the program. This symbol must be used only for terminating an input; it should not be used as a program symbol.

Symbol specifications. Any numeric, alphabetic, or alphanumeric symbol of one to five characters in length is permissible. Certain symbols have special uses which are given below. The typewriter controls such as upper case, lower case carriage return etc. are not considered by the assembler as characters. The symbols "TEMP" and "temp" are indistinguishable as are "()" and "90," or "-" and "+."

Explanatory Notes (Ref. Sample Assembly)

1. Starting location and reference address. The reference address is the

LGP-30 USERS' ORGANIZATION - POOL

"base number" of the addresses, i.e. the number from which the addresses (as distinguished from the locations) are numbered. In the present example, with reference address = 4000, the address "beta" = 4004. If the reference address were 0000, the address "beta" would be 0004. In either case, the program itself is stored starting at 4000.

2. Undefined symbols. The symbol "gamma" is "undefined" in the sense that it does not appear in the "location" column, and hence no numeric address can be associated with it. In such cases "/u" is printed following the symbol, and the easily recognized hex pattern "qqqqqqqq" is stored in the given memory location.

3. Multiply-defined symbols. The symbol "beta" is used to represent two different locations (lines 5 and 11 of the "p2" code). Each time a location symbol appears after its initial appearance, the characters "/m" are printed following the command of the given instruction. When the code is assembled on the second pass, the stored address corresponding to a multiply-defined symbol is the address assigned to it on its first appearance in the code. Thus "beta" = 4004 in line 1 of the "p2" printout, rather than 4010.

4. Instructions with absolute addresses may be input by prefixing an "x" to the operation, as for PIR input.

5. Hexadecimal constants may be input, as illustrated, by using "x" as the last character of the symbol designating the location of the constant. The eight-character word must be split into two four-character words for input, since they are input as 6-bit characters and converted to 4-bit by LGPSAP. Leading zeros are not required for either half of the word. Thus:

,3089ql72 is input from tape as 3089!ql72!

,0009ql72 can be input as 9!ql72!

,00000002 can be input as !2!

,40000000 can be input as 4000! !.

6. Instruction-form constants may be input, as for PIR, in the form xz!AAAA!.

7. Temporary storage locations, counters, parameters, etc. may be symbolically specified as illustrated; they will then be set to zero during assembly. Symbols ending in "x" may be used here.

OPERATION OF THE ASSEMBLER

For operation the following sequence of steps should be executed:

1. Load input tape in Flexowriter (or Photoreader).
2. Using 4-bit input, type manually .000AAAA, where AAAA is the start fill location of the assembly subroutine LS. Depress START COMP lever on Flexowriter.
3. Depress 6-bit input button.
4. Lift MAN INPUT on Flexowriter (if using reader, switch to reader input instead).
5. Depress START COMP lever again. The Flexowriter will print "p1" and the starting and reference addresses will be input. After about 2 minutes, the rest

LGP-30 USERS' ORGANIZATION - POOL

of the tape will be input for the first pass. Any multiply-defined symbol error checks will be printed out as noted. Possible error stops may occur (see below). When the symbol "end" is reached, the Flexowriter prints out "p2" and the program stops, indicating that the second pass may be started.

6. Restart the tape in the Flexowriter to input the first word of the program proper (immediately following the reference address). Depress START COMP.
7. After the second pass is completed, a new tape may be loaded and the assembler restarted by simply depressing START COMP.

ASSEMBLY OUTSIDE THE "ALLOWABLE RANGE"

The assembler is self-protecting, and will input a program only into that portion of memory separating the assembler itself from the symbol tables, and not occupied by either. The symbol tables occupy the last 16 tracks in memory permitting the use of up to 512 different symbols in a single program. The output routine is fixed at 0300. If LS is loaded at 0700, the maximum range of locations 1232 to 4763 will be available for program assembly.

If it is desired to locate a program out of this range, for example starting at 5000, this may be done either by the use of K2-71 (see below) or as follows: Assemble the program within the allowable range, specifying 5000 as the reference address. Using program 13.2, output a hexadecimal tape of the stored program and change its "v" load instruction to load the tape at 5000. This illustrates the purpose of the reference address function of the assembler.

Preparation of Repositionable Punched Tape

Repositionable decimal punched tapes are readily prepared for the assembled programs by use of the POOL Program K2-71. Note that if the recommended initial locations of 0300 for the D-3 tape and 0700 for the LS tape are used, the program for punching must be entered after the assembly has been completed. By this technique it is possible always to use a standard initial location for the assembled program and to reposition it as desired later. The "modifier" used will be the same as the "reference address" of the assembly routine.

ERROR STOPS

During the first pass, the Flexowriter types out indications of the following errors:

| <u>Flexowriter Output</u> | <u>Error</u> | <u>Remedy</u> |
|-------------------------------|--|--|
| "ob" | Assembly is "out of bounds"; that is, not within allowable range given above | Relocate assembly and restart |
| "st" | Capacity of symbol table has been exceeded (should occur only rarely; possible only with large programs) | Easiest solution is to divide program into two or more subroutines and assemble separately |

LGP-30 USERS' ORGANIZATION - POOL

SYMBOL TABLE:

Tracks 48-63 inclusive are used for the symbol table and the symbol address table. Time is saved in storing symbols in the table in this program by the use of a random number method for the determination of the final locations of the symbols. The last nine bits of the six-bit pattern for the symbol are treated as a number from which a random address within the table is generated. If this address is not occupied it becomes the location for the symbol. If it is already occupied, the next address is then tested. Uniqueness is assured during the second pass by a comparison of the symbol sought with the symbol already stored. Further details are given in the Appendix.

LGPSAP SUBROUTINES

LGPSAP consists of two subroutines: (1) the assembler proper, designated LS, and (2) the instruction printout subroutine, designated D3. It also uses PIR 10.4 (see below). Subroutine D3 is a modified version of the decimal memory printout routine (21.0) and hence prints out hex words in fractional or hex-decimal form according to the setting of the TRANSFER CONTROL button. A list of the changes required in program 21.0 to obtain D3 is included below. Following this is the assembly of LS in LGPSAP code and decimal code relative to 0000.

The subroutine assembly is as follows:

| <u>Subroutine</u> | <u>Load At</u> | <u>Memory Space Required</u> |
|-------------------|--|--|
| D3 | 0300 | 0300 - 0663 |
| LS | Relocatable, but maximum space is available for program assembly when loaded at 0700 | Five and a half tracks, plus locations 4800 - 6363 for symbol and symbol-address tables |
| PIR 10.4 | 0000 | 0000 - 0263 Subroutine LS uses the binarize subroutine of PIR 10.4. (Note: other versions of PIR may not be used here). |

TIME

On the first pass, the program will input about 17.5 instructions per minute, and on the second pass, about 9.5 instructions per minute, using the format illustrated for the assembly of LS (see below). These rates would be somewhat slower if the symbolic location, operation and address were separated by tabs, or if more comments were inserted (conversely, a program without any comments could probably be input at the rate of 11 or 12 instructions per minute on the second pass).

These figures are relatively unaffected by the length of the program. More specifically, an increase in the number of unique symbols used in the program will not increase the symbol-table "lookup" time for any given symbol, until the number of unique symbols begins to approach the maximum allowable 512. (The programming logic for accomplishing this was suggested to the author by Mr. George Feeney of the General Electric Company).

The present version of LGPSAP is unoptimized; a further reduction of input time could doubtless be realized by full or even partial optimization of the code.

LGP-30 USERS' ORGANIZATION - POOL

APPENDIX: The Random Address Generator

The operation is given in the flow chart in the first box following variable connector branch V1A, as follows:

$$\text{Bits } 1 - 9 \text{ (WD * MPLR mod } 2^{30}) \rightarrow R,$$

where the symbol is to be stored in the Rth line of the table. The LGP-30 instructions corresponding to this (ref. the LGPSAP symbolic code) are:

| <u>Loc.</u> | <u>Op.</u> | <u>Address</u> | <u>Comments</u> |
|-------------|------------|----------------|--------------------------------|
| V1A | B | WD | |
| | N | MPLRX | (WD * MPLR) mod 2^{30} at 29 |
| | M | 1A21 | Bits S - 8 → Bits 21 - 29 |
| | E | NMXM1 | Extract Bits 21 - 29 |
| LS15 | H | R | and store |

The locations referred to contain the following:

| | | |
|-------|------|---------------------|
| WD | | the current symbol |
| 1A21 | XZ | 0400 1 at 21 |
| NMXM1 | XZ | 0763 mask |
| MPLRX | ,5K2 | 1KGF 5^{11} at 30 |

In other words, the equation for the "random number" function could be expressed as

$$R = \text{Integer} \left\{ [(S \times 5^{11}) \bmod 2^{30}] \times 2^{-21} \right\}$$

Where R is as defined above and S is the value obtained by regarding the symbol as a number at q = 30; R ranges from 0 to 511. The incorporation of this search-saver into the routine reduced average assembly time by about two-thirds.

TABLE OF SYMBOLS FOR THE LGPSAP FLOW CHART

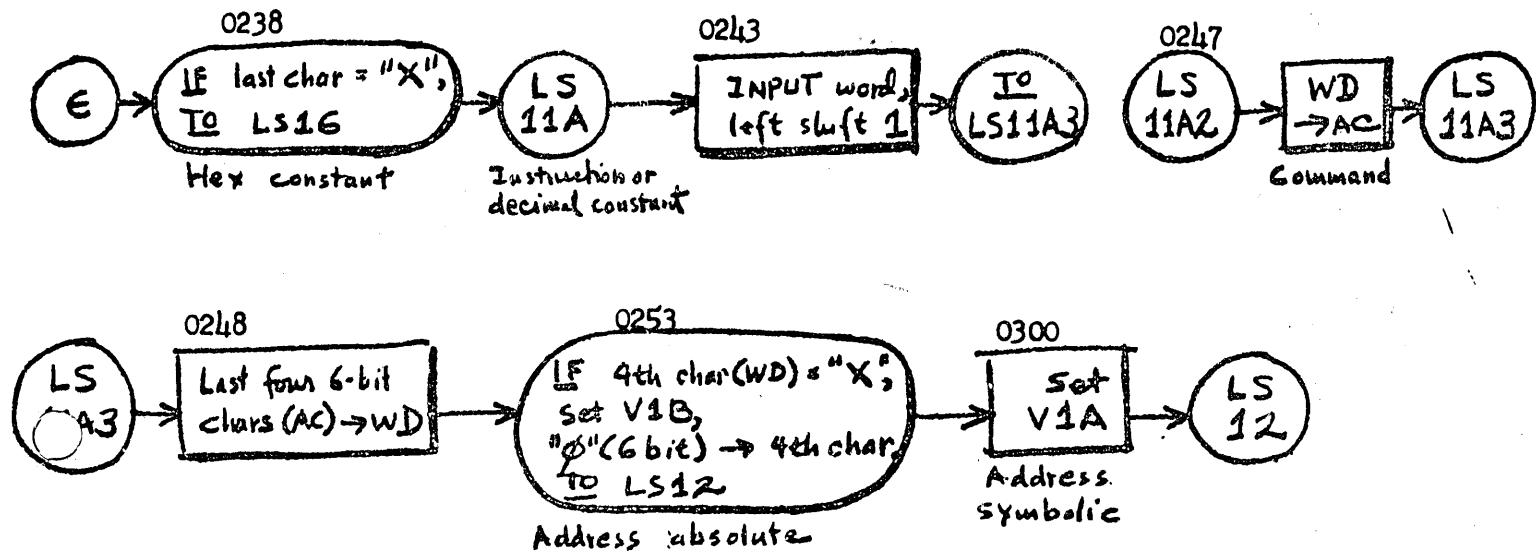

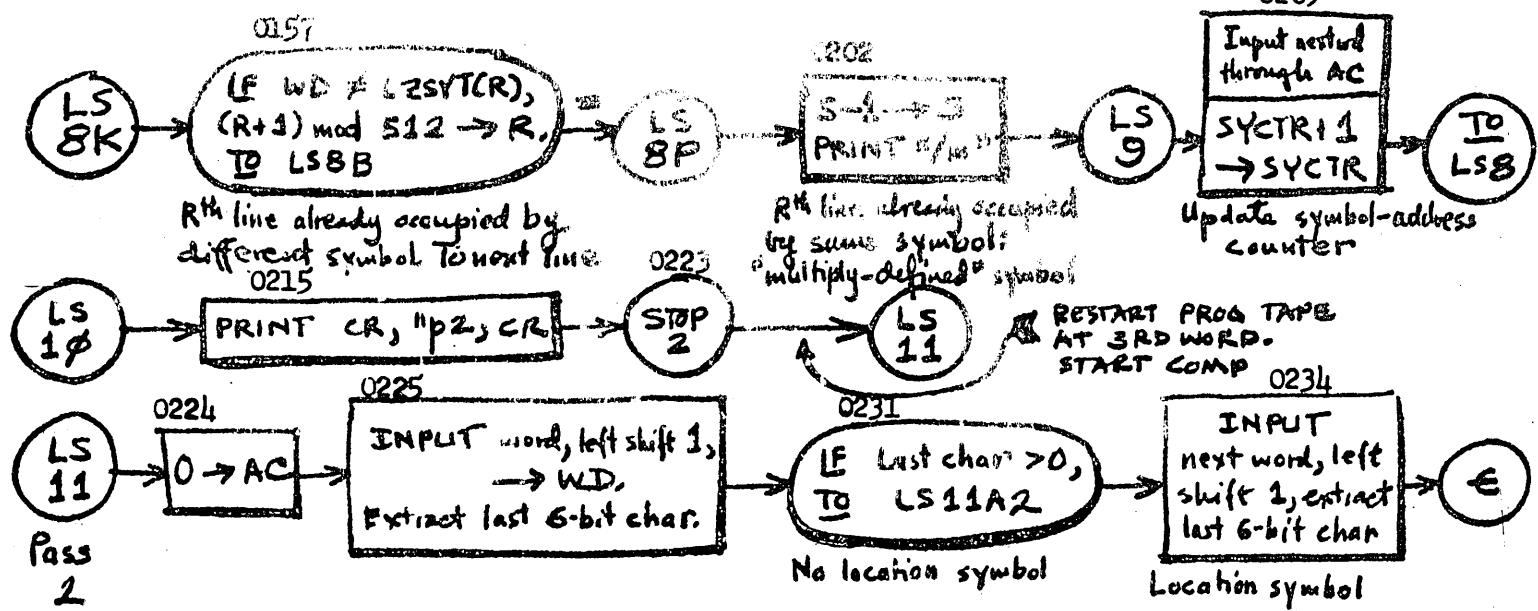

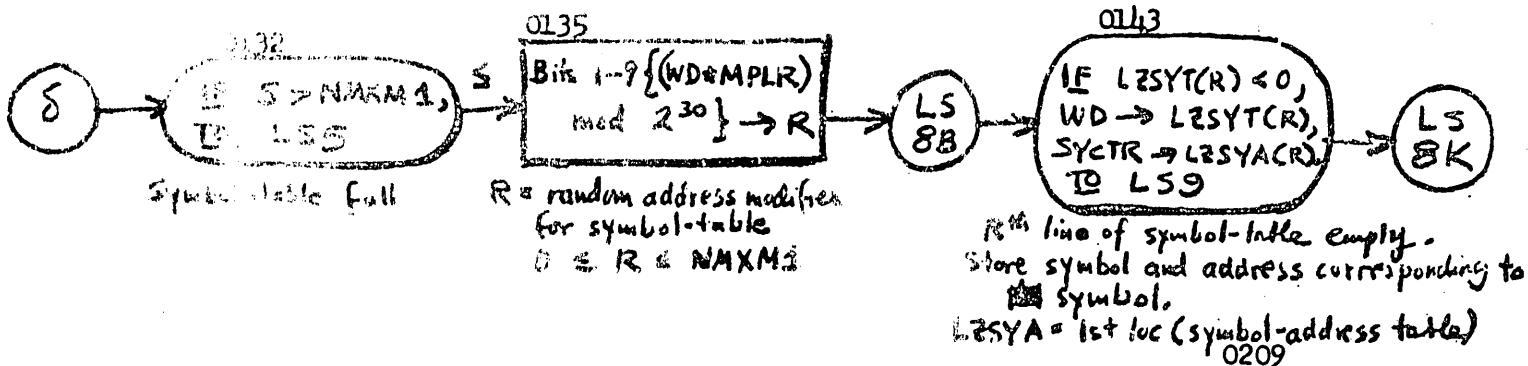

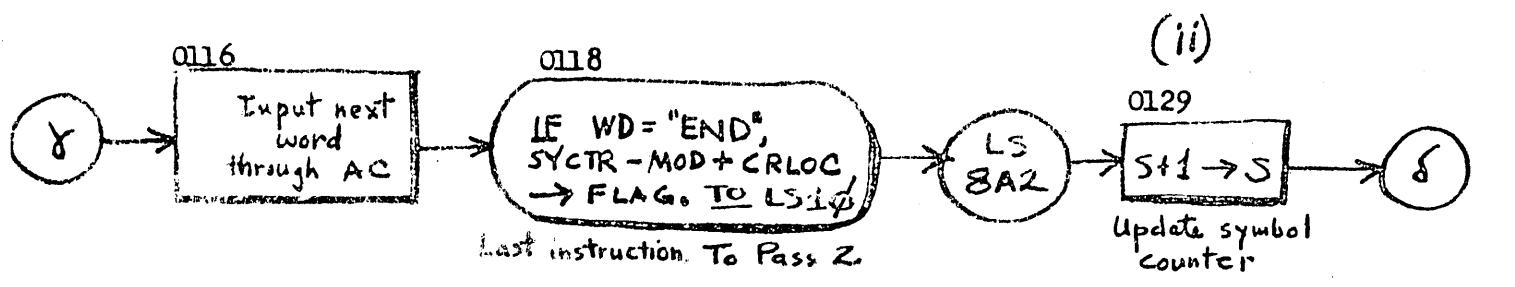

| | |
|----------|---|
| BINZ | Binarize |
| CR | Carriage Return |
| CRLOC | Current location of program being assembled |
| FORBT | Convert from 6-bit to 4-bit characters |
| LGSYT | Address of a line in the symbol table |
| LLSPI | Last location +1 |
| LZSYA | First location of the symbol-address table |
| LZSYA(R) | Rth line of symbol-address table |
| LZSYT | First location of the symbol table - 1 |
| LZSYT(R) | Rth line of symbol table |
| MOD | Modifier |
| MPLR | Multiplier for computing random address ($=5^{11}$) |
| NEGWD | Negative word (=wwwwwwq) |
| NMXMI | Number of lines in the symbol table - 1 |
| R | Random address modifier for symbol table |
| S | Index for lines of symbol table |
| STLOC | Starting location of program to be assembled |
| SYCTR | Symbol address counter |
| WD | A temporary storage location |
| WKLOC | A temporary storage location |
