DATA TERMINAL **TECHNICAL INFORMATION**

HEWLETT  **PACKARD**

1.0 INTRODUCTION.

The Sweep Module interfaces the display controller of the terminal to the CRT. It generates all drive signals and specialized voltages required by the CRT display. Parts lists for the CRT Monitor Assembly (02644-60001) and Cable Assembly (02640-60138) are contained in section 13255-91001.

2.0 OPERATING PARAMETERS.

A summary of operating parameters for the Sweep Module is contained in tables 1.0 through 4.0.

Table 1.0 Physical Parameters

- 3.0 FUNCTIONAL DESCRIPTION. Refer to the block diagram (figure 1), schematic diagram (figure 2), timing diagram (figure 3), component location diagram (figure 4), and parts lists (02640-60028, 02640-60039, 02640-60040, 02640-60042, 02640-60084, 02640-60095, and 02645-60008) located in the appendix.
- The Sweep Module consists of video, vertical and horizontal drive circuits, a width voltage regulator and a high voltage power supply.
- 3.1 VIDEO DRIVE.
- 3.1.1 The function of the video drive circuit is to interface the low level logic input signals from the display section of the terminal to the higher levels required to drive the CRT.
- 3.1.2 The video amplifiers Q1 and Q2 are common emitter amplifiers with Q3 acting as an active pullup. Components R6 and CR2 protect the video transistors during CRT flashover. The video section is built on its own ground plane to prevent the very large and fast current transients that it generates (100 milliamperes in 20 nanoseconds) from interfering with the sweep circuits.
- 3.2 VERTICAL DRIVE.
- 3.2.1 The vertical drive circuit generates the vertical scanning waveform which causes the electron beam in the CRT to be moved from the top to the bottom of the screen.
- 3.2.2 Operational amplifier U2 is connected as an integrator. Components C2, R11, and R10 control the slope of integration and therefore, the height. FET Q4, discharges C2 during retrace and resets the integrator. Transistor Q13, interfaces the TTL Vertical Drive (VDR) signal to the levels required by the FET. The output of the integrator is ac coupled to the vertical output amplifier by capacitor C4. AC coupling is used at this point to center the vertical sweep about ground, thus providing positive and negative current to the yoke. A small offset is caused when the integrator resets rapidly and waits for the Vertical Drive to go high; but this offset can easily be corrected by the centering rings on the yoke.

Transistor array U3, and transistors Q5, Q6, Q7, and Q14 (with their associated components) form a differential input amplifier which is capable of driving the vertical deflection yoke. Yoke current is sensed by R17 and compared with the output of the integrator. The integrator output is adjustable from approximately 1 to 2 volts (100 to 200 milliamperes deflection current).

3.3 HORIZONTAL DRIVE.

- 3.3.1 The horizontal drive circuit generates the horizontal scan which sweeps the beam from left to right on the face of the CRT.
- 3.3.2 The Horizontal Drive (HDR) signal is buffered by open-collector gate U5 and applied to transistor Q11. When the Horizontal Drive is low, Q11 is on. Horizontal output transistor, Q12 is biased off, while the primary current of T1 increases to the value determined by R20 (about 200 milliamperes). When the Horizontal Drive goes high, Q11 turns off and the primary current of T1 is transferred to the secondary and turns on Q12. During the time that Q11 is off, C8 charges to the supply voltage and supplies a large turnoff current for Q12 when the horizontal drive again goes low. Transistor Q15 and its circuitry regulate the +12 volt supply down to 11 volts so that the drive to the horizontal transistor is kept constant.
- 3.3.2.1 Components Q12, CR6, C9, C10, the horizontal yoke, and the flyback transformer primary form a "ringing" horizontal sweep circuit. Sweep is initiated from the center of the screen when Q12 is turned on. This causes C10 to start to charge toward VREG through the yoke. The current increases to 2.5 amperes while C10 charges to -5 volts. At this point, Q12 is turned off and the current flows through C9 charging it rapidly to 300 volts. By this time the yoke current has decayed to zero and reversed direction. The flyback (voltage across C9) now decays rapidly and would go to -300 volts except that diode CR6 clamps it to VREG. Since this fixes the voltage across the yoke, the current now starts decreasing linearly toward zero. The current has now reversed direction and discharges C10. When the current has almost decayed to zero, Q12 is turned on and the cycle is repeated.
- 3.3.2.2 The linearity coil (L1) is not necessary for operation of the horizontal circuit, but is used to compensate losses in the yoke during the sweep. The coil has an apparent negative resistance resulting from the core material used and the fact that it is applied in an inductive circuit. The primary of the flyback transformer is necessary to provide a ground return for the collector of Q12 and provides a convenient method of generating the bias voltages necessary to drive the CRT.

3.4 WIDTH VOLTAGE REGULATOR.

3.4.1 This circuit regulates the width of the display by varying the voltage applied to the horizontal drive circuitry.

3.4.2 The width supply is a negative supply regulator using a voltage regulator in conjunction with a complementary transistor Darlington. Transistor Q8, acts as a current limiter and restricts the current to 0.8 amperes. This is necessary to protect the printed-circuit board and the flyback transformer from being destroyed in the event that Q12 shorts. This circuit keeps the width constant during varying current requirements and allows a method of varying the width without using inductors.

3.5 HIGH VOLTAGE POWER SUPPLY.

3.5.1 The high voltage power supply generates the various voltages required by the CRT which are not supplied by the terminal power supply. These voltages are -100V, 30V, 500V, and 15,000V.

3.5.2 The lower voltages are all generated by half-wave peak rectification of the horizontal flyback pulse. The 30-volt supply for the video circuits is Zener regulated to protect the video transistors from high voltages which could destroy them. Gap Caps C18, C19, and C20 provide additional supply filtering and act as spark gap voltage transient protection during CRT flashover. The CRT Ultron supply voltage is generated by a tripler which multiplies the peak-to-peak output voltage of the flyback (approximately 5 kilovolts) by three, rectifies it, and filters it. The tripler also contains a bleeder resistor to discharge the CRT when the circuitry is off. This prevents potential shock from the CRT when it is disconnected during servicing. The bleeder also serves to improve supply regulation. Under light loads, the flyback output "rings" (due to leakage inductance in the transformer). The bleeder resistor damps this "ringing" and prevents it from causing poor regulation.
