1311 DIAGNOSTIC TEST 0020Write Addresses on Disk Pack**A. SCOPE:**

This program writes indelible addresses on 1311 Disk Packs. The addresses are five digits in length and are written sequentially starting with the track specified by the address which is entered via the console typewriter. The test terminates when the last track of the specified disk storage module has been written. Addresses can be written on additional disk storage modules by repeating the test and entering a new five digit starting address.

This test can be used to write addresses on the CE Disk Pack. Addresses will be written on all cylinders except 00, 34, 35, 36, and 99.

The program provides the option of saving the data on each sector or generating data for each sector when writing the sector addresses.

B. SETUP:

1. While running the test, the program switches have the following functions:

Switch 1 ON Bypasses error timeouts

OFF Allows error timeouts

Switch 2 ON Generates data for each sector

OFF Saves data on disk pack

Switch 3 ON Halts on error

OFF Bypasses halt on error

Switch 4 ON Loops test

OFF Halts on test completion

-2-

B. SETUP (cont.):

2. During the keying in of data, if the user makes an error typing in data on the console typewriter, he can turn console Switch 3 on, press release and start, turn Switch 3 off, and re-enter the data.

3. File Switches:

Write Address Switch -- ON

Compare Disable Switch -- ON (OUT)

4. Normal Setting of Console Switches

Program Switches -- As Desired

Data Switches -- Program

5. The user should insure that the PACK ON and READY lights on the Disk Storage Drive are ON.

6. Loading Program

- a. Clear core by inserting and executing 31 00003 00002

- b. Paper Tape Input

- (1) Load tape in reader.
- (2) Insert and execute 36 00000 00300.
- (3) After core has been loaded, depress START key.
- (4) Follow typed out instructions.

- c. Card Input

- (1) Place cards in reader hopper.
- (2) Place 1620 in manual mode.
- (3) Depress load key.
- (4) After core has been loaded, depress START key.
- (5) Follow typed out instructions.

Note: When using this test with the CE Disk Pack, yes must be keyed in in answer to the question "Are you using CE Disk Pack."

If no is keyed in, the head alignment data on cylinders 00, 34, 35, 36, and 99 will be destroyed.

C. DETAILED EXPLANATION:

This test is designed to write the indeleble addresses on 1311 disk packs with the option of either saving the data that is on the sectors or writing known data on the sectors. The test has been written in routine form, and groups of routines perform certain logical functions. The routines that perform logical functions are:

Control Routine

Seek Cylinder Routine

Write Addresses Routine

Check Addresses Written Routine

Test Complete Routine

Error Routine

The Control Routine is comprised of a group of routines. The name of the test, operating instructions, and switch functions are typed out by these routines. Input data required for the proper operation of this test is entered during the execution of the Control Routine. A check that the entered address is not on cylinders 35 or 36 is made; the disk unit drive code digit is generated from the module number entered; and the address of the first sector of the track is calculated. If known data is to be written on the sectors, this data is generated in the Control Routine.

The following input must be entered during the execution of the Control Routine: (See Note At Bottom of Page 2)

1. Yes or no, entered from the console typewriter.

Normally the answer to this question is YES; because the test is being used with the CE Disk Pack. Typing in YES provides for a program check to prevent writing on cylinders 00, 34, 35, 36, and 99. If NO is entered, no program check is made of the cylinders being written on and the head alignment data will be destroyed if used

C. DETAILED EXPLANATION (cont.):

- with the CE Disk Pack. A typeout occurs (DO NOT USE ON CE DISK PACK), if NO is entered to warn the user that all cylinders will be written on.
2. A one digit number, the module number of the Disk Storage drive on which the Disk Pack is located, is entered from the console typewriter.
3. A five digit sector address indicating the starting track on which addresses are to be written is entered from the console typewriter.
- To write all addresses, key in 00000. If YES was keyed in as the answer to whether or not the CE Disk Pack is being used, the sector address entered is checked that it is not on cylinders 35 or 36. If the entered address is on one of these cylinders, an error message will type out requesting that the address be entered again. A new address should be entered which is not on one of these cylinders.

The drive code digit must be calculated from the module number keyed in because of the format of the Disk Control Field. The calculation of the drive code gives the following results:

| <u>Module No.</u> | <u>Drive Code</u> |
|-------------------|-------------------|
| 0 | 1 |
| 1 | 3 - |
| 2 | 5 - |
| 3 | 7 - |

This drive code is then set in the F₀ position of the Disk sub-instructions.

The starting address of the track containing the addresses entered is calculated. This is always an even digit in the tens position and zero in the units' position; i. e., XXXEO. If the tens' digit entered is even, it is the starting address, but if it is odd, the starting address is one less than the tens' digit entered.

C DETAILED EXPLANATION (cont.):

The status of program switch 2 determines whether the data on the sectors will be rewritten (switch 2 off) when the addresses are written or whether generated data will replace (switch 2 on) the previous data on the sectors. The routine to generate a track (2100 characters) of data is entered if switch 2 is on. A typical sector of the data generated is:

0000000000111111112222222222...88888888899999999999

The twenty, five digit address are inserted in their respective positions before the data is written on the disk pack.

Prior to giving the access mechanism a seek command to position at the proper cylinder for writing, a check is made as to whether the CE Disk Pack is being used or not (entered information). If the CE Disk is being used, a check is made to verify that cylinders 00, 34, or 99 are not being accessed. If the cylinder is 00, the address is updated to cylinder

01 and the test continues; if the cylinder is 34, the address is updated to cylinder 37 before programming is continued; and if the cylinder is 99, the program enters the test completed routine. If the CE Disk Pack is not being used, this routine is bypassed.

The Seek Cylinder Routine positions the access mechanism and then checks to see if a Select Lock condition exists.

The Write Address Routine checks program switch 2 to determine if the data on the Disk Pack is to be saved or not. If it is, a Read Disk Track Numerically without wrong length record check (RTN) is executed. The new (generated) disk addresses are placed in their proper positions in the data just read in, and then a Write Disk Track without wrong length Record Check (WTN) is executed. A check for parity errors is made after the RTN and WTN instructions.

The Check Addresses Written Routine makes a double check to insure that the addresses were written on the Disk Pack. The first check is the execution of a check Disk Track Numerically without wrong length record

C. DETAILED EXPLANATION (cont.):

check (CTN). The second check is a program compare of each of the addresses read from the Disk Pack. A RTN instruction compares the Disk Addresses against the addresses in the data used in the WTN instruction, Write Address routine. If both of these checks give positive indications, the addresses have been written on the Disk Pack. Error messages are typed out if the results are negative.

The Check Addresses Written Routine also contains a routine to determine if a complete cylinder has been written. If it has, updating is performed and the Seek Cylinder Routine is entered. A check is also made to determine if the entire Disk Pack has been written. When it has, the Test Completed routine is entered.

The Test Completed Routine checks if any errors occurred while the program was being run, if the error timeouts were bypassed, and then types out the appropriate message.

The Error Routine is entered whenever a Parity Check is detected or a program compare indicates an incorrect result. It contains the necessary instructions to control whether or not an error message will be typed out, whether or not the program will halt on an error, or whether or not the program will loop on an error.

D. ERROR ANALYSIS:

CANT USE CYLINDERS 00, 34, 35, 36, 99 ON CE DISK PACK

ERO 00930, 00954

This error type out will occur if the user keys in a sector address that is on cylinders 35 and 36, and he has the CE Disk Pack on the storage drive. The program will request the sector address again.

ERROR OCCURRED BUT SWITCH 1 WAS ON, THUS NO ETO

ER8O 02430

This error type out will occur in the test completed routine if the user has switch 1 ON and an error occurred during the

D. ERROR ANALYSIS (cont.):

running of the test. ETO = Error Type Out.

AAAAAAA BBBBB (XX) CYL ZZ HDY

All other error type outs follow this standard format.

AAAAAAA is the Disk Storage Command on which the error occurred. All disk operations in this program are without Wrong Length Record Check.

BBBBBB (XX) is the error that occurred and turned on ANY DATA check. (XX) is the indicator number.

CYL ZZ HDY gives the cylinder number ZZ (00-99) and the head Y90-9) addressed when the error occurred.

The AAAAAAAA type outs that can occur are:

READ TRACK A1 ER2 01530

The program is reading from a track on the Disk into area A1 in memory.

WRITE TRACK ER3 01710

The program is writing from area A1 in memory onto a track on the Disk Pack.

READ BK TK CK ER4 01782

The program is doing a read back track compare of the data written onto the Disk Pack out of area A1 in memory.

READ TRACK A2 ER5 01842

The program is reading the track written back into area A2 in memory.

PROG COMPARE ER6 01986

The program is doing a compare of the sector addresses written from area A1 and read back into area A2.

SEEK ER8 01458

The program has performed a seek operation.

D. ERROR ANALYSIS (cont.):
BBBBBB (XX),

The BBBB type errors are:

| | | |
|------------------|------|-------|
| ADS CK (36) | ER10 | 02574 |
| WLR CK (37) | ER11 | 02694 |
| OVFO CK (38) | ER12 | 02718 |
| RD CK (06) | ER14 | 02754 |
| WR CK (07) | ER15 | 02778 |
| MBR-E (16) | ER16 | 02802 |
| MBR-O (17) | ER17 | 02826 |
| FILE NO IND (39) | ER13 | 02718 |

The program found Any File indicator on, but all the indicators which turn it on are off.

NOT/EQ ADS ER18 02010

The program during the compare of the sector address found one that was not equal. The program attempts to rewrite that track of addresses again.

SELECT LOCK ER19 02574
CYL ZZ HD Y ER20 02934

This is the rest of the error type out that tells the user which cylinder (CYL) the error occurred on, where ZZ will be from 00 to 99, and also which head (HD) or track was in error, where Y will be from 0 to 9.

E. SERVICE HINTS:

1. The test also contains a routine that will loop on a write instruction (write disk track numerically without record length check). This routine has to be entered via execution of a branch instruction in the insert area (49 03114). This routine changes a no operation instruction to a branch and branches to the main program for the data as to which module number and sector address is to be used.

E. SERVICE HINTS (cont.):

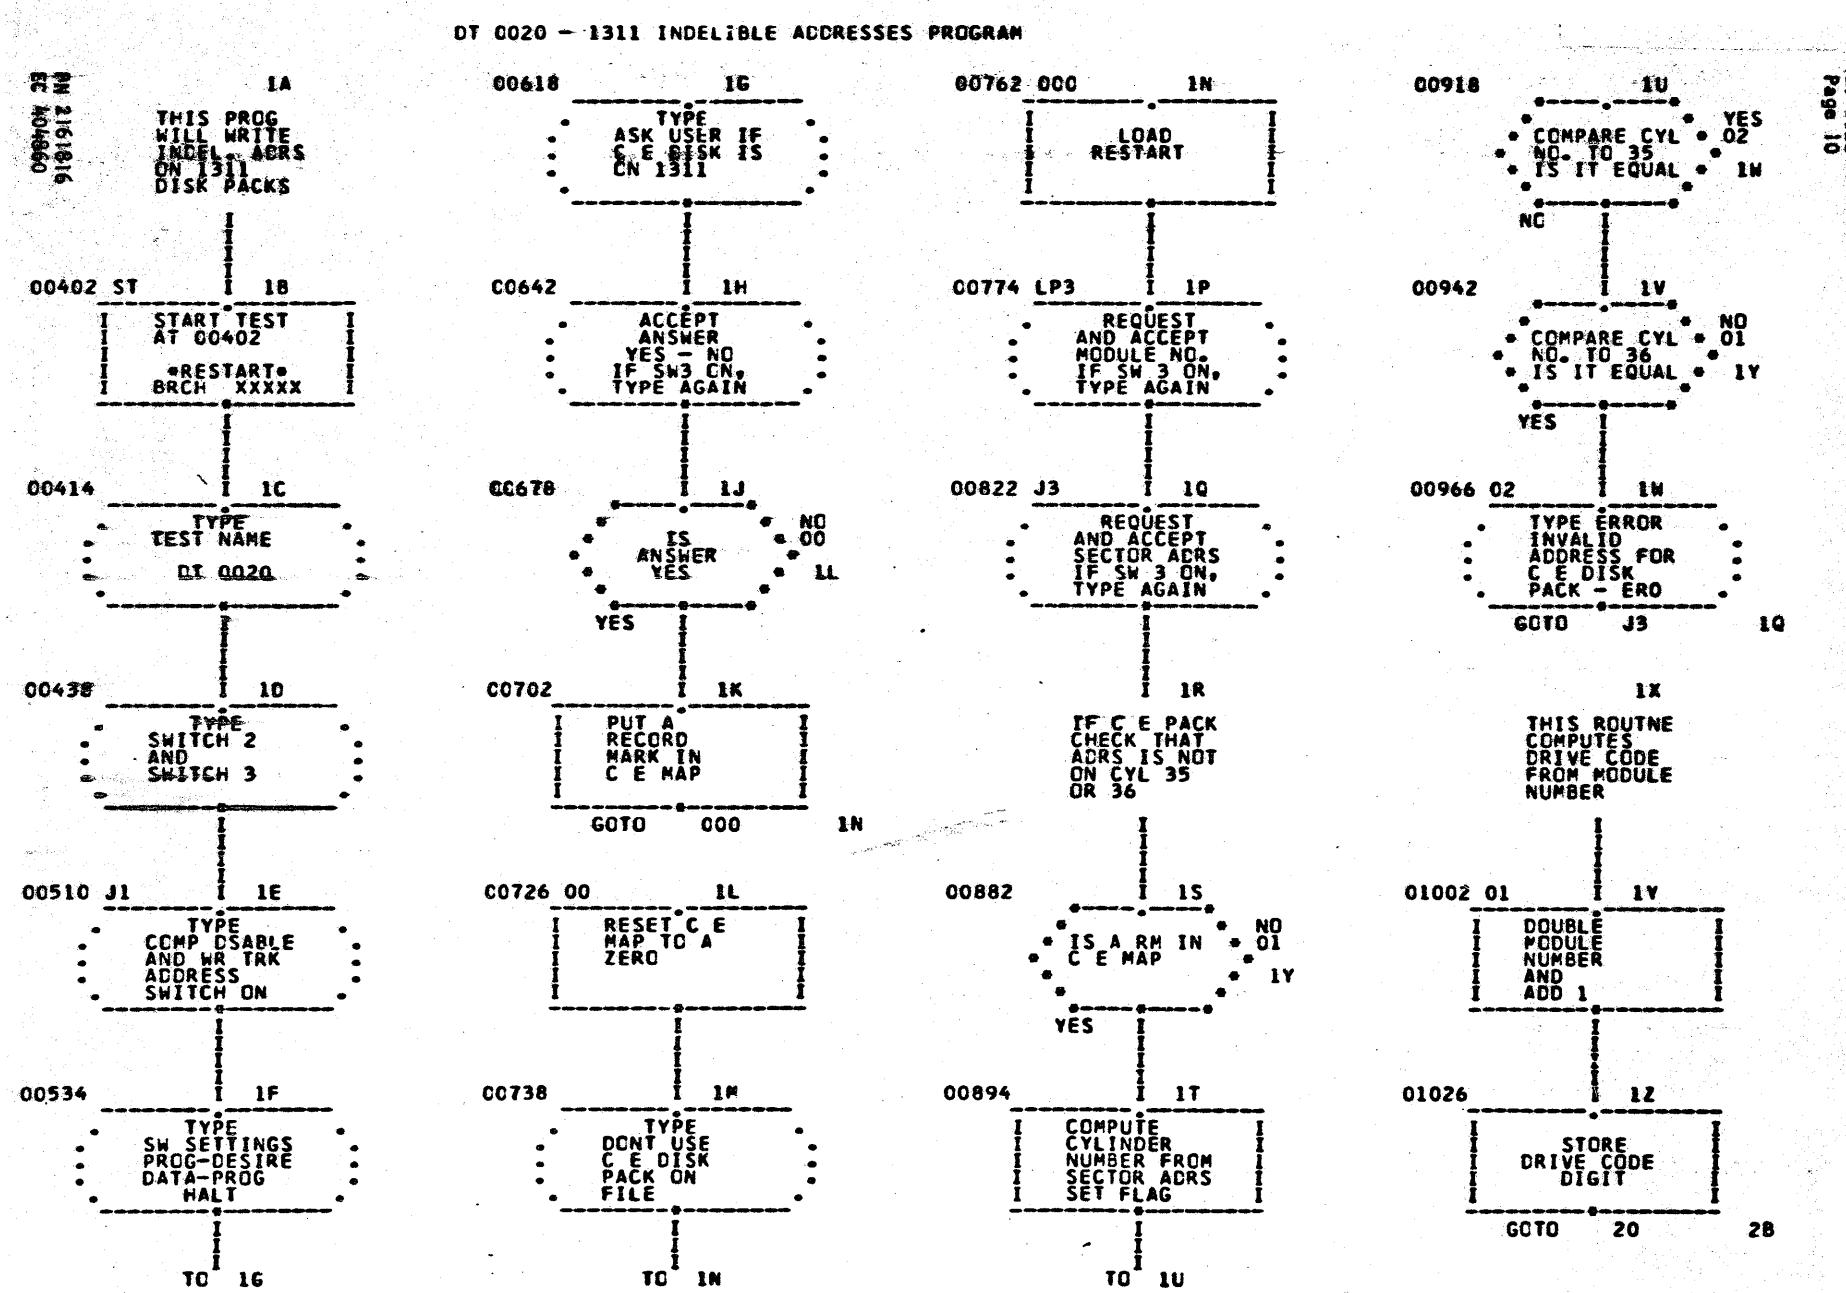

This is request from the user. The routine utilizes the write instruction in the main program. This write instruction is continually executed until the user turns console switch 4 off.

The routine then changes a branch to a "NOP", and branches to the test complete routine in the main program.

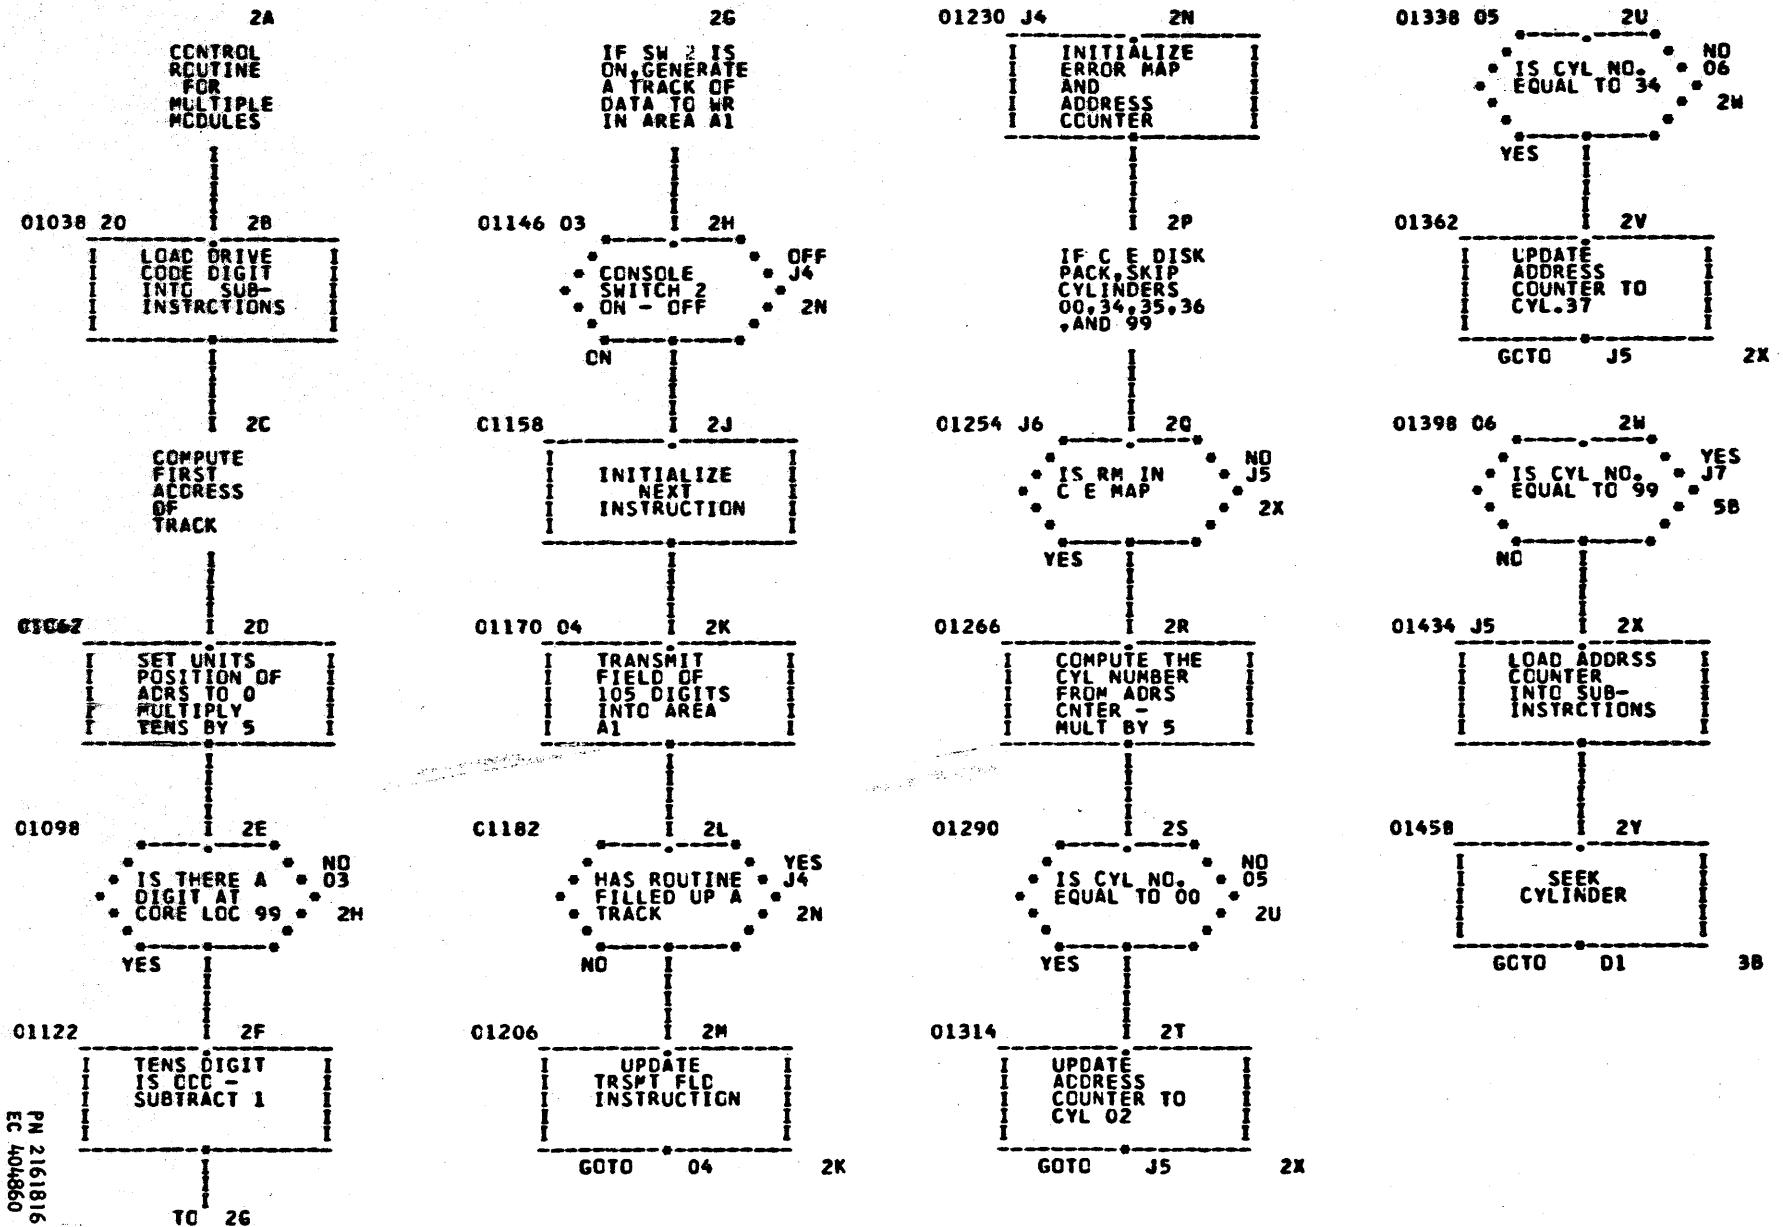

2. This program was designed to fulfill the need to write addresses on the 1311 Disk Pack. However, it can also serve two other functions:

a. It will detect bad spots on a Disk Pack if these interfere with the magnetic pattern on the disk. This is detected by parity errors during a Read Operation, should parity errors occur. The head and cylinder number associated with the error will be typed out with the error message. The user may then dump the data read onto the typewriter to determine, by examining the characters, which sector is bad. This is done by inserting and executing a 35 XXXXX 00100 where XXXXX is the core location of the data area in core. The XXXXX's can be determined by looking at the subinstruction of the Disk operation that error occurred on.

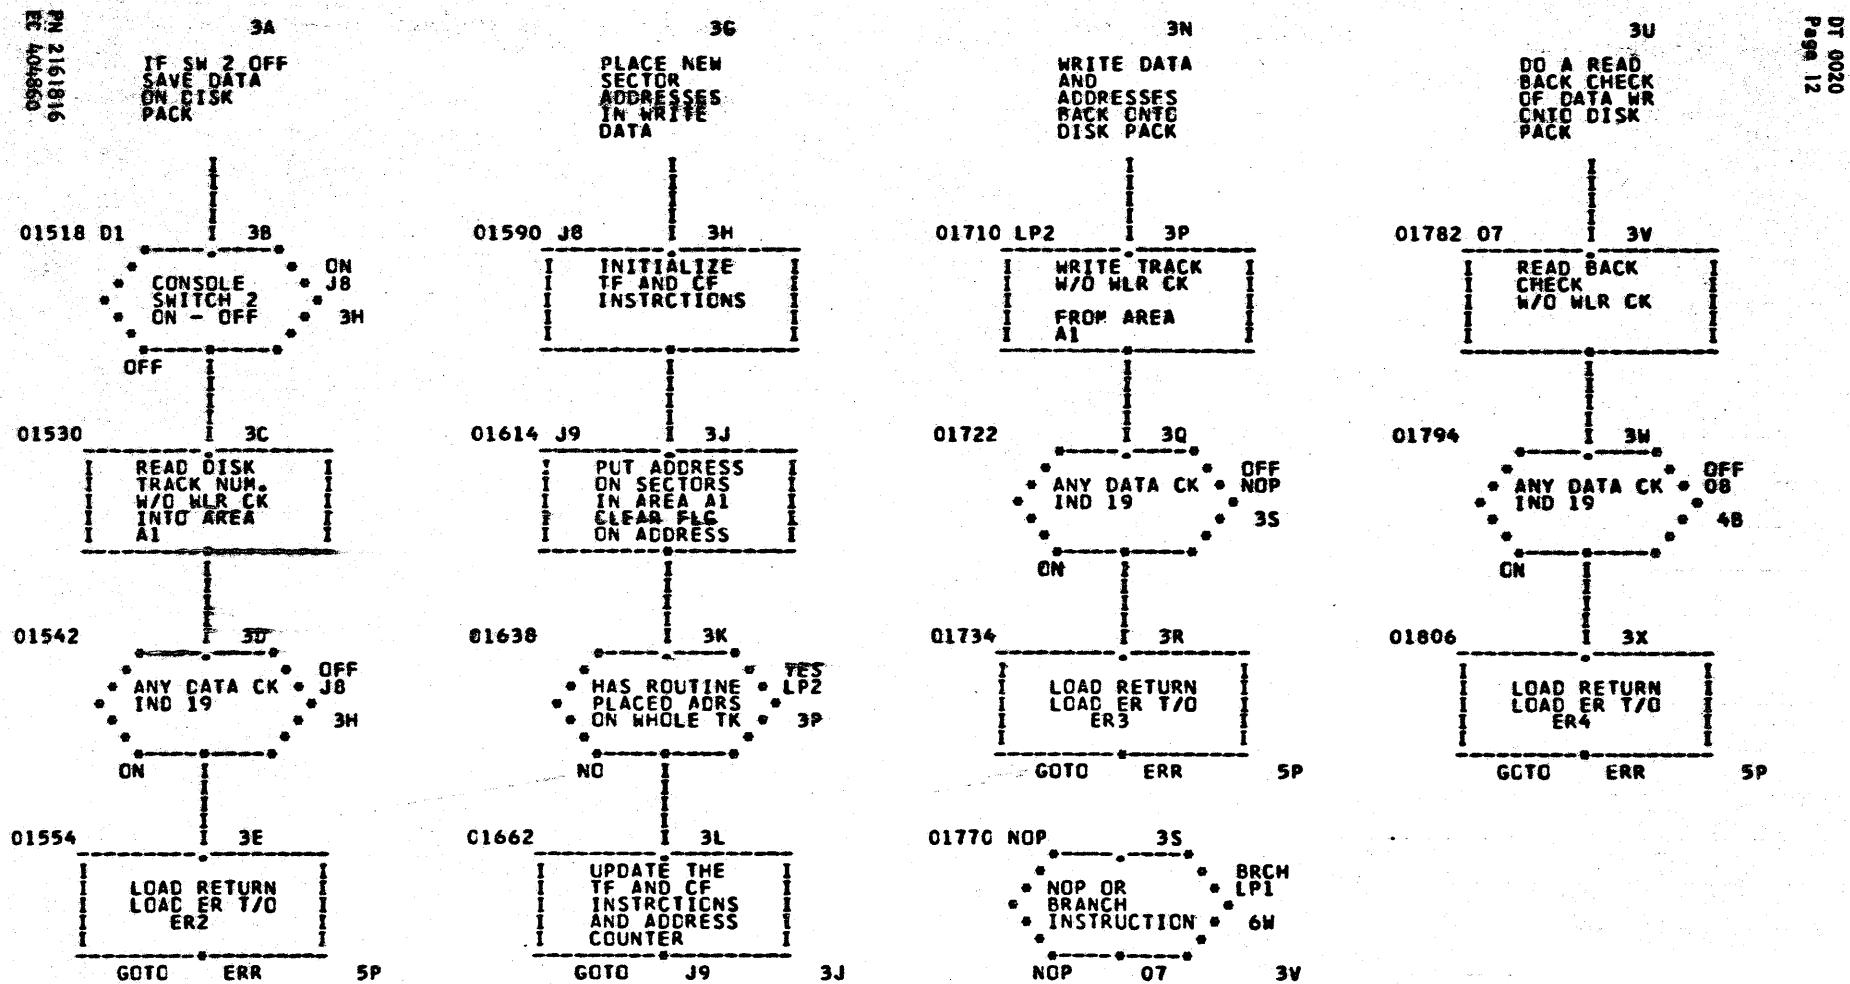

b. This program will write addresses on the Disk Pack beginning with the starting track address of the track on which the sector address keyed in is on. As a Seek operation is executed for each cylinder and as the operation progresses through higher consecutive cylinders until the addresses are written on cylinder 99, the user can watch the access arms to determine if the Seek operation is successfully seeking the cylinders (i. e., access arm will progressively reach farther into the Disk Pack).
