1. PURPOSE

The Sense Switch Interrogation Program(SSIP) provides the maintenance engineer a standard method of control and monitoring of maintenance programs. This control is provided through the maintenance bits of maintenance console and options are defined below.

2. PROGRAMMING INTRODUCTION

2.1. General

Functions have been assigned to the sense switches so that, if they are all off or the machine is not in Maintenance Mode, the tests will run in Normal Mode. In Normal Mode, all the test routines will be run in order, once, and then the machine will stop. If any errors occur, the test in which they occurred will be identified by a print out. No other printouts will occur and testing will continue. In Normal Mode the interruption system will be disabled unless a specific test enables the interrupt system in order to test interruption.

The SSIP monitor, when activated, monitors continuity within the maintenance program. It may be activated (or enabled) by replacing a branch instruction, location 002543.0, with a NOP. After a sequence error, the monitor will return control to the last previous in sequence point.

Only ERS and SSW exits are monitored. Manual branches to the first instruction of a test may be made from either half word of the maintenance bits. In this case no monitor error will occur if the branch is left in the bits.

Paragraph 3.2. lists the sense switch options available. Appendix A is a flow chart of the sense switch interrogation routines.

2.2. Communication

2.2.1. Entry Points

1. SSW-location 1301.0, normal exit for sense switch interrogation.
2. ERS-location 1302.0, error exit for sense switch interrogation (not normally used).

3. SERS-location 1304.0, special exit for error when test is not complete. It provides for return to the maintenance program at the instruction following the SIC, SEN; B, SERS. The B, SERS should not be a BD or BE because control will not be monitored in SSIP.

2.2.2. Return points from the SSIP to the maintenance program are provided by Instruction Counter Storage into the following locations:

1. SEN, location 1310.00, receives IC on SERS exit.
2. SENO to SEN 31, location 1311.00 to 1350.40, receives IC on exit from SSW and ERS. The number, ie, SENn, (where n is a number) gives the relative location of the loop address. It is word count from the first instruction in the routine to be executed to the branch to SSW or ERS. It provides the return address for a loop option.

2.2.3. At the beginning of each test routine, the maintenance program will store the routine identity in location DPET13 (1437.00).

2.2.4. The maintenance program will branch to SSW at the beginning of the program to provide for the initial set up of the SSIP.

2.3. Output From SSIP

Output from the SSIP will be through the operators console printer unless suppress printing option is selected. Output from monitoring routine or forced identity printouts may occur as noted below even though the suppress printing option is selected.

At the beginning of each test section of a maintenance program, the program will store the section identity and branch to the SSIP. The program will store the identity in location DPET13, address 1437.0, and branch to the SSIP at location IDF 1 (1443.0) or IDF2 (1444.4). The IC will be stored in RET (1306.4).

The normal exit to the SSIP will be IDF1. If sense switch 36 is active and the console printer (typewriter) is ready, the heading will be printed and control will be returned to the maintenance program at the instruction following the SIC, RET; B, IDF1.

If the maintenance program branches to IDF2 in SSIP, sensing sense switch 36 is bypassed and printing will occur if the console printer is ready.

2.3.1. Print Formats

1. Identity Print

1200

The section identification is the only thing printed with SSW36 active and a branch to IDF1 or a branch to IDF2.

2. Single Error Print

1200 005673.4

The section identification precedes the octal address. The octal address is the stored instruction counter from an active branch to SERS or ERS.

3. Total Error Count - SSW34 active

1200 005677.0 0059

Section identity is printed. The octal address is the stored instruction counter from an active branch to ERS or SSW. 0059 is the decimal error count during 100 passes through the routine. This count may be a maximum of 9, 999. If the error count is zero printing will not occur.

4. Indicator Printout as a result of an Interrupt

1200 005317.4 IJ

1200 is section identification, will be SSIP if SSIP had control at interrupt. 005317.4 is the address of the instruction following the one causing the interrupt.

IJ-Mnemonic name of the indicator causing the interrupt.

2.3.2. Printout from Monitor

When the SSIP monitor is enabled, printouts will occur on the console printer independent of the sense switch settings. The printout will contain a statement "IN SEQ AT" or "OUT OF SEQ AT" and an address. The address will be the IC stored on a branch to SSW or ERS.

2.4. Interrupts and Resets

The SSIP has within it a master interrupt table. It requires the initial setup for locating it in the normal operating area and to set the proper interrupt address (address 2.0). The interrupt address (starting location of the table) is INT, location 1353.0. Any program intentionally producing interrupts should modify this table to prevent an indicator printout. An indicator printout will be interpreted as an error by the maintenance engineer. The address to modify will be INT plus the indicator number, ie, AD is indicator 16 so INT + 16.0 may be changed to a branch to the maintenance program indicating success. The next branch to SSW or ERS will restore the interrupt table to its initial condition. Additional conditioning with each branch to SSW or ERS follows; the interval timer will be loaded to a maximum, the indicator mask will be restored, the boundaries and control bit will be reset to zero, the interrupt address will be reset, and indicators will be cleared.

3. OPERATING PROCEDURES

3.1. Loading Procedures (PUNFUL Cards)

3.1.1. Equipment

1. SSIP Binary Deck

2. Desired Maintenance Program Decks.

3.1.2. Procedure

1. Push Master Reset button

2. Place Interrupt disable in the inactive position.

3. Place Time Clock disable switch in the inactive position.

4. Place maintenance switch in active position (Maintenance Mode). Note: If maintenance switch is inactive, the SSIP will run as in normal mode, ie, no SSW active, regardless of position. Programmed halts in SSIP may be bypass under this condition.

5. Place sense switches in the desired location (see 3.2 below). Reference: note under 3.1.2.4. above.

6. Depress IPL key (initial program load) on operators console.
7. Place SSIP card deck in the card reader hopper. The control card at front of deck should have the chain flag set or word count sufficient to prevent initiating the SSIP.
8. Push the Start pushbutton on the card reader.

When the "out of material" light comes on the SSIP is in memory. To load the maintenance program proceed as follows:

9. If SSIP monitoring is desired, replace Branch in SSIP with NOP (Addr 2543.0).
10. Depress IPL key on operators console.
11. Place maintenance program deck in the card reader hopper.
12. Push the Start pushbutton on the card reader.

If the control word of the deck has the proper word count, after the deck is read in the first word of the program just read in will be executed. This instruction should be an active branch which will start the program.

3.2. Options

Sense Switch (Maintenance Bits)	Effect of setting to 1
32	Suppress error print out
33	Stop on error
34	Repeat each test 100X and print number of errors
35	Repeat current test indefinitely

36	Print out section identity
37	Repeat block of tests
38	Start each test Enabled
39	Spare
	If SSW 33 is on and 32 is off, printing will occur before the halt. If SSW 34 and 35 are both on, the test will be repeated indefinitely in blocks of 100X each with the error count being recorded. Use of SSW 37 and 61 are not available in card loaded versions of SSIP.

3.3. Output Media

The output from the SSIP will be by console printer (typewriter) when available. The error halt may be used instead of the console printer (see options above).

4. PROGRAM PHILOSOPHY

The SSIP is a package of routines providing a uniform method of control and output from sigma area maintenance programs. The present SSIP (PUNFUL card loaded) does not control the reading in the maintenance program. It therefore must rely on the maintenance programmer to give control to the SSIP to provide for an initial setup at the beginning of his program. This permits SSIP to housekeep registers and tables that will be used later. If monitoring for continuity is desired, the branch at 2543.0 will have been replaced with a NOP and a dummy pass into the monitor routine will also occur. The housekeeping will consist of setting interval timer to all ones, setting boundaries and the control bit to zero, setting interrupt address, transferring the interrupt table to its operating location, indicators will be cleared, and the mask will be reset. The indicator mask will be as follows; 0-25, 28, 33, and 34 set and the remaining mask bits will be cleared. Each time a maintenance program branches to SSW or ERS, the above housekeeping will occur before control is returned to the maintenance program (except during looping).

The MP (maintenance program) will again branch to SSIP with the section identity stored in DPET13. Branching to IDF1 will cause the identity to be printed if SSW 36 is set. Branching IDF2 will cause the identity to be printed independent of SSW 36 setting (Both contingent on console printer being ready and both independent of SSW 32 settings). Control is returned to the instruction following the branch to IDF1 or IDF2.

Index register 13 is used throughout the SSIP and will not be restored on return to the MP. All other index registers will be restored if used.

SENSE SWITCH INTERROGATION PROGRAM

An error halt (SSW33 active) requires a manual branch from the maintenance bits to continue.

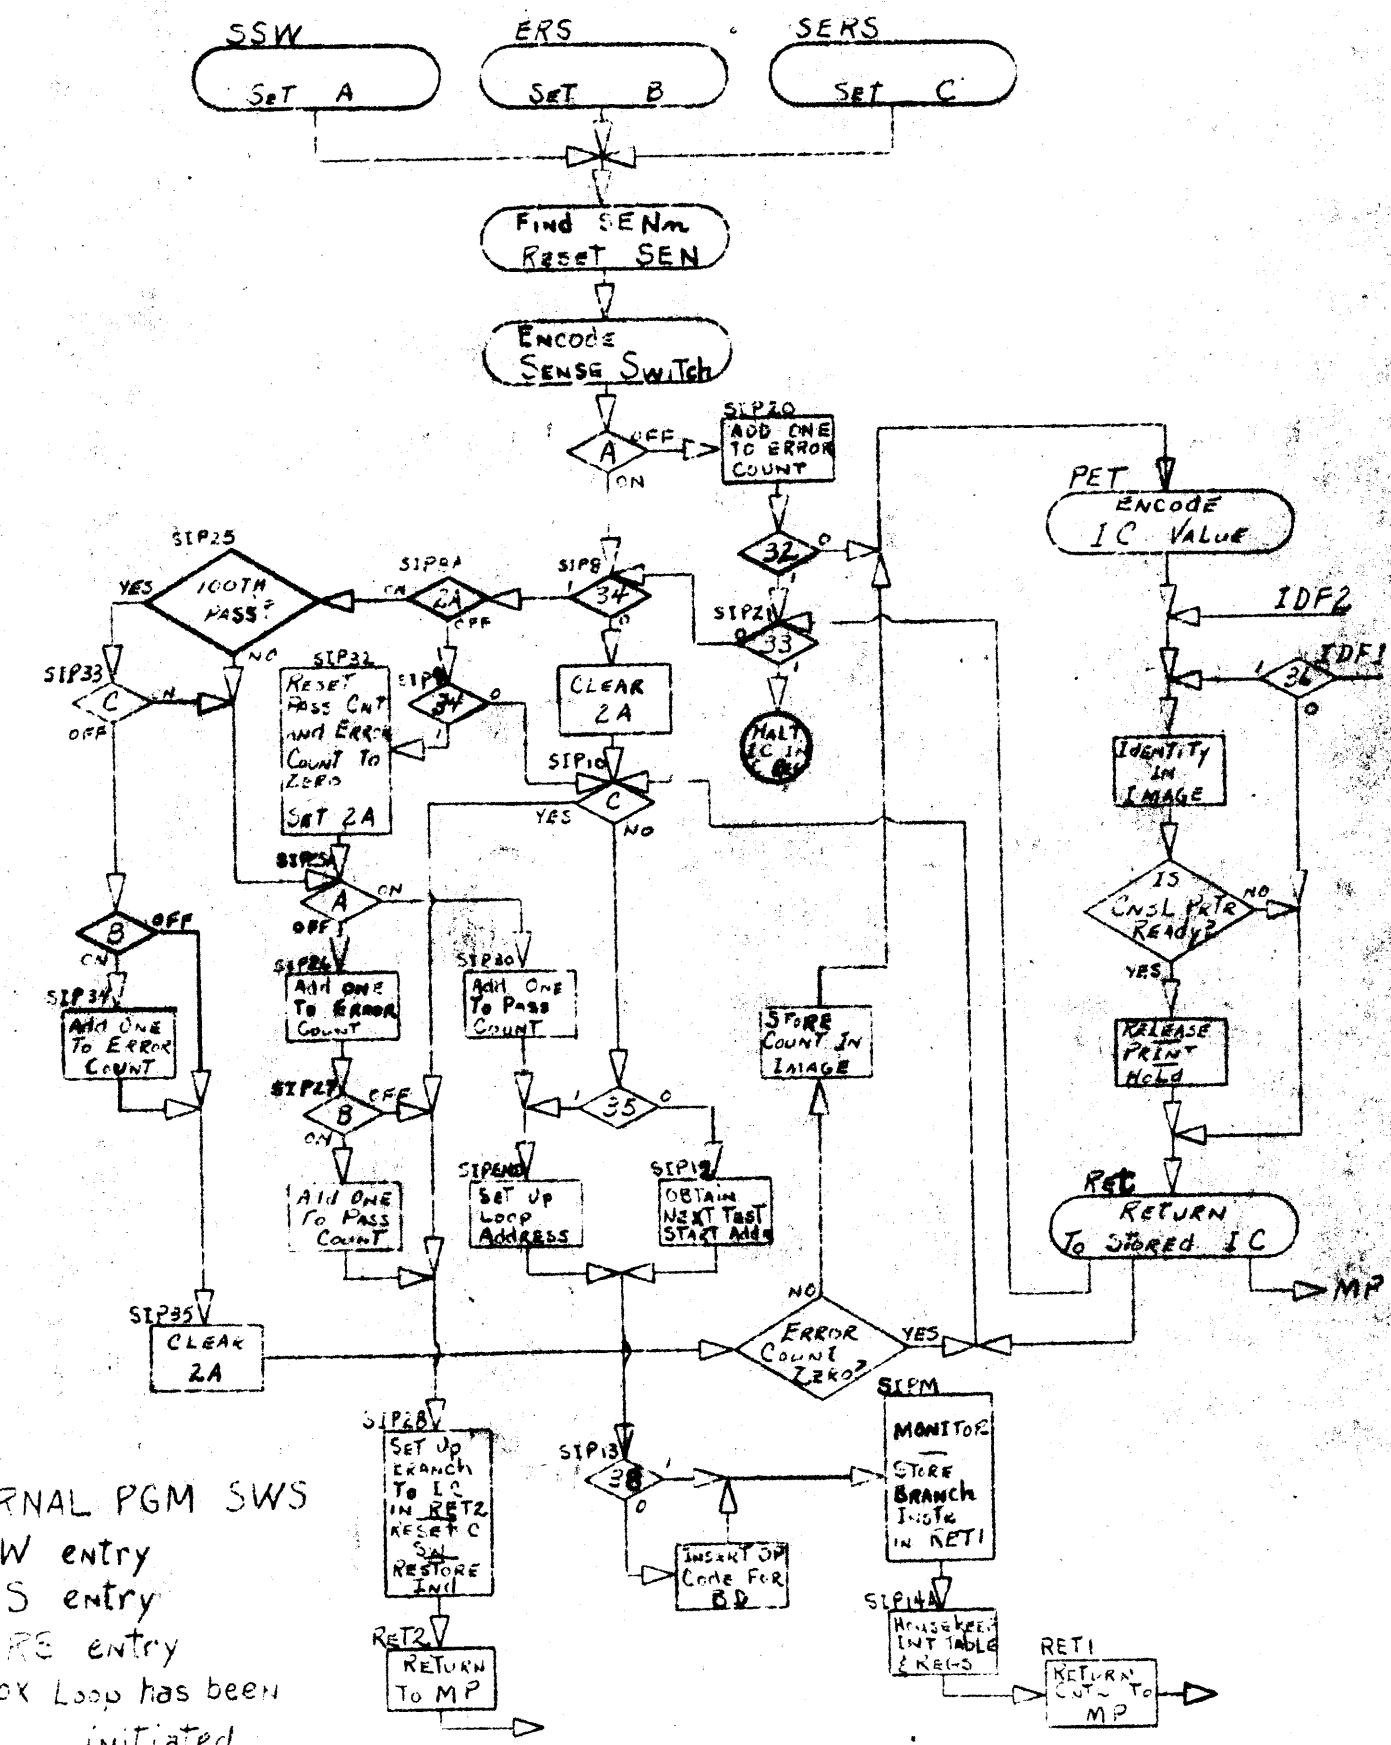

After the MP gains control after branching to IDF1 or 2, testing will begin. Whenever an error is detected the program will indicate this by branching SIC, SEN; B, SERS. This should not be an enabling or disabling branch because SSIP will return control to the MP in the same manner it was received. SSIP rechecks the sense switches, prints unless suppressed, and continues if halt is not requested. If the 100X loop has been requested the error count is stepped one and control is returned to the MP.

When the MP completes a routine, it will SIC, SENn; B, SSW (or ERS). Normally ERS is not desired because it may cause an error indication that was previously given. Otherwise the exits are the same. The sense switches are read and the results are stored (At this point the error print occurs for ERS). Next the 100X loop option is checked. If 100X loop option has been started a check is made of pass count. If entry was through ERS the error count is increased by one. If this is not the 100th pass, the pass count is increased by one and index registers are restore. Control is returned to the MP at the starting address of the loop. If this is the 100th pass, the looping switch (memory location) is cleared. The error count is checked and printed unless count is zero.

The unconditional loop option is now checked and return to start of loop is requested.

If looping is not requested, the SSIP determines the first instruction of next routine. Sense switch 38 is now checked to determine if control is to be returned system enabled or disabled. The machine environment is restored (housekeeping) as stated above and control is returned to the MP.

The interrupt table is made up of 48 memory locations; one for each indicator that can cause an interrupt. When an interrupt occurs the system will get a free instruction. This instruction is determined by the address stored in the interrupt address register (location 2.0) plus the indicator causing interruption. In the SSIP interrupt table the free instruction will be SIC, INTZ; BD, INT (n). From here the indicator mnemonic name is obtained for printout. If the console printer is ready the print out occurs and control is returned to the MP at the instruction following the instruction causing the interrupt. The MP may replace the free instruction with a branch to their own program as a check for specific interrupts.

12 -OPERATING INSTRUCTIONS FOR MONITOR

11 -
10 -1. TO ENABLE ADDRESS MONITORING SET THE

9 -FIRST BRANCH BELOW TO A NOP.

8 -
7 -2. PRINT SUPPRESS AND STOP ON ERROR SWITCHES

6 -HAVE NO EFFECT ON MONITOR.

5 -
4 -3. AFTER A SEQUENCE ERROR MONITOR RETURNS

3 -CONTROL TO THE PREVIOUS IN SEQUENCE POINT.

2 -
1 -4. SSW AND ERS BUT NOT SERS EXITS FROM

-THE TESTS ARE MONITORED.

-5. MANUAL BRANCHES TO THE FIRST INSTRUCTION

-OF A TEST MAY BE MADE FROM EITHER

-HALF WORD OF THE KEYS WITHOUT CAUSING

-A MONITOR ERROR IF THE BRANCH IS LEFT IN

-THE KEYS.

-6. MONITOR ONLY REQUIRES AGREEMENT

-BETWEEN CALCULATED AND ACTUAL ADDRESSES

-PLUS OR MINUS TWO.

-7. THE SECOND ADDRESS IS USED IN A BRANCH TO A BRANCH
