INTRODUCTION

The 650 Simulation Program presented in this manual is an interpretive routine for the IBM 705 Electronic Data Processing Machine which in effect transforms the 705 into an IBM 650 Magnetic Drum Data Processing Machine. The program was designed and written primarily as an aid in the transition from a basic 650 system to a 705 system and does not provide for simulation of a 650 with additional features. The logic of this 705 program parallels very closely the internal logic of the 650 itself; persons familiar with 650 operation and with 705 programming will readily understand the functions of the various routines.

It should be clearly understood that the 650 Simulation Program usually will not obviate the necessity of rewriting 650 programs for the 705. For efficient 705 operation, and in order to take full advantage of the greater capacities and speed of the 705, all applications should be completely re-programmed including the re-designing of the basic flow charts, or block diagrams. Nevertheless, the simulation program can be very useful. The necessity of rewriting all 650 programs before the installation of a 705, and release of the 650, is removed; those programs not rewritten before conversion may be treated in an orderly fashion allowing sufficient time for writing efficient 705 programs. In addition, it is possible that at a given installation a few 650 programs are used so infrequently as to make rewriting more expensive than inefficient operation of the 705. For one-time problems or once-a-year jobs, the use of the simulation program might be feasible almost indefinitely. Another possible application of the simulation program is in an installation which includes both a 705 and a 650 when the 650 is not available or is overburdened on occasion.

Certain features of the 650 Simulation Program limit its usefulness and restrict its application. One important factor to be considered is the speed with which a 650 program functions under 705 control. Because of the length and complexity of the simulation program, the 705 will produce 650 output at a slower rate of speed than will the 650. The difference in operating speeds of the 650 as simulated on the 705 compared with an actual 650 will vary depending on the degree of optimizing in the 650 program, the incidence of the various 650 instructions, and sundry other factors. Another feature to be considered is the necessity of programming the mapping routines which perform the functions of the 533 Read-Punch Unit control panel. (See "Simulation of the 533 Control Panel Functions," page 7 and "Notes on Programming of Read Mapping and

Punch Mapping," page 14.) Because of this feature the 650 Simulation Program is available in the form of a deck of 705 symbolic instruction cards in which symbolic blocks 90-97 are available for programming the mapping routines. After the mapping instructions have been written, card punched, and inserted in the deck, it is necessary, of course, to assemble the complete deck.

The 650 Simulation Program decks (symbolic instruction cards) are available from:

702/705 Program Librarian

New York 22, New York

MAIN FEATURES OF THE PROGRAM

705 COMPONENTS REQUIRED

To make the 650 Simulation Program as widely applicable as possible it was designed for use with the 20,000 memory position 705. Both 650 memory (2000 words) and the simulation program are contained in the 20,000 memory positions of the 705. If the program is to be used on a 705 with 40,000 memory positions, certain modifications are advisable. Allocation of the first two memory quadrants to the pseudo 650 drum and elimination of the PAC and UNPAC subroutines from the present program will result in a substantial increase in operating speed.

Only a 714 Card Reader and a 722 Card Punch are required in addition to the basic 705. It may be desirable, however, to use tape input instead of card input for the 650 load cards and data cards; this procedure is discussed under "Operating Notes."

705 MEMORY AREA ASSIGNMENT

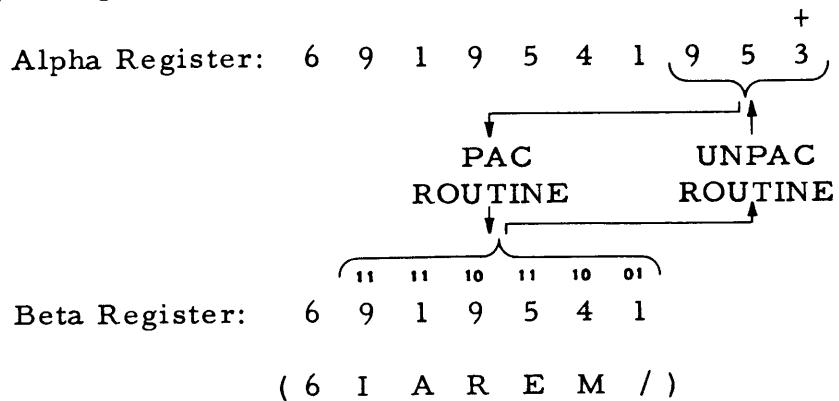

The 20,000 positions of 705 memory are allocated as follows:

00001 through 14000	- Simulated 650 Drum
14005 through 18019	Simulation Program
19730 through 19999	
18020 through 19729	- Available for simulation of control panel wiring.

SIMULATION OF 650 MEMORY

The 2000 word 650 drum memory is represented in the first 14,000 positions of 705 memory. This is accomplished by packing each ten-digit 650 word and its sign into seven 705 characters before it is placed in the 705 memory area representing the 650 drum. The sign of the 650 word is placed over the second digit from the left, and the three low order digits are removed, converted into quaternary zone representation, and placed over the third through seventh digits from the left. Thus, the zone portion of each of these five characters represents a factor of zero, one, two, or three times the assigned value of 256, 64, 16, 4, and 1, respectively, according to the position of the quaternary zone digit. In other words, a three-digit decimal number is converted into a five-position quaternary number in binary coding. The figure following shows a

schematic representation of this process of conversion and the reverse process of unpacking.

Explanation:

Conversion to Quaternary Number System } $953 = \underline{3} \times 256 + \underline{2} \times 64 + \underline{3} \times 16 + \underline{2} \times 4 + \underline{1} \times 1$

Binary Coding: 11 10 11 10 01

Zoning Position in Beta }
Register, from the left } 3rd 4th 5th 6th 7th

The + sign, coded on the 705 as zone bits "11", is placed over the second digit from the left in the Beta Register.

SIMULATION OF THE 650 ARITHMETIC UNITS

The 650 arithmetic units are represented by a twenty-digit pseudo-accumulator and a ten-digit pseudo-distributor in the 705 memory. Reference to the functions of these components is made in the following pages.

SIMULATION OF THE 650 CONSOLE

The methods of simulating the various lights, switches, and keys of the 650 console are described below. For easy reference, a complete listing of the 650 console components with their 705 counterparts is included under "Operating Notes."

The Display Lights and Display Switch are simulated by a 705 typewriter write-out of any 650 word. To display a word from the simulated drum, i.e., to READ-OUT STORAGE, the drum address is entered in the

simulated address selection switches (symbolic location 16.19.0 for this operation) and a manual transfer is made to 705 symbolic location 16.77.0 from the 705 console. Both the 650 drum address and the ten-digit word, with its sign, are typed out with appropriate identification, followed by 705 Program Stop 1111. Depression of the start key will cause the next higher drum word to be displayed. The format of the typewriter message is as follows:

650 ADD. XXXX XXXXXXXXXXXXX+WORD

To display the contents of the distributor, the accumulator, and the program register, a manual transfer is made to 705 symbolic location 16.25.0. The contents of the three units are typed out with an indication of the signs of the distributor and the accumulator and with appropriate identification for each component, as follows:

DIS XXXXXXXXXXXXX+ ACC XXXXXXXXXXXXXXXXXXXXXXX+
P. R. XX XXXX XXXX

705 Program Stop 2222 follows this message. Depressing the start key will cause a transfer to the beginning of the Interpretive routine and thus effects resumption of operation. (Simulation of the READ-IN STORAGE function of the 650 display switch is obtained by entering the information from the 705 console - see next paragraph.)

The Storage Entry Switches are represented by ten characters in the 705 memory at symbolic location 80.00.0. The sign switch is simulated by the zone portion of the character in the units position. Information may be entered directly from the 705 console or by means of a card in the card reader. The latter method is recommended for initializing the storage entry switches and is discussed more fully under "Operating Notes."

The Operation Lights, Address Lights, and Operating Lights are simulated functionally by typewriter messages. Thus, each instruction executed when the simulated half-cycle mode has been put into effect by the necessary alteration switch setting (see below) is shown by the following message: The words "HALF CYCLE" are typed first and then the contents of the distributor, the accumulator, and the program register are written out with appropriate sign indications before interpretation and execution of the next instruction.

The Address Selection Switches are represented by two groups of four characters each in 705 memory. The four characters at symbolic location

16.24.0 represent the address selection switches with respect to the address stop feature. The other four characters represent the address selection switches with respect to the READ-IN STORAGE and READ-OUT STORAGE functions, and are found at symbolic location 16.19.0.

The Programmed Switch is simulated by means of the 705 alteration switch 0911 in conjunction with appropriate instructions in the simulation program. When 0911 is set to the OFF position a 650 stop code will be executed, and the contents of the distributor, the accumulator, and the program register will be written on the typewriter preceded by the words "650 STOP CODE." Operation may be resumed by depressing the start key. With 0911 set to the ON position a 650 stop code will be executed as a No-Op instruction.

The Half-Cycle Switch is simulated with the 705 alteration switch 0913 and related program instructions. When 0913 is set to the ON position, one 650 instruction is executed each time the start key is depressed. Each instruction executed is written on the typewriter preceded by the words "HALF CYCLE," as well as the contents of the distributor and accumulator with appropriate identification.

Control Switch simulation is effected by means of the 705 alteration switch 0914 and associated program instructions. This switch is turned to the ON position to obtain operation of the address stop feature. The 650 address is stored in symbolic location 16.24.0 representing the setting of the address selection switches. At the time of the address stop, the typewriter writes the words "ADDRESS STOP" followed by the contents of the distributor, the accumulator, and the program register. Depressing the start key causes resumption of operation. Setting 0914 to the OFF position is the equivalent of the 650 control switch in the RUN position; the MANUAL setting is covered by the routine itself.

Overflow Switch simulation is accomplished with the 705 alteration switch 0912 and related instructions. This switch is set to the ON position for overflow SENSE and to the OFF position for overflow STOP. When a stop on overflow occurs, the contents of the distributor, the accumulator, and the program register are written out on the typewriter preceded by the word "OVERFLOW." Operation may be resumed by depressing the start key. When the simulated overflow switch is set to SENSE, i.e., 0912 is set to ON, and an overflow other than quotient overflow occurs, an "A" is placed in the overflow register (at symbolic location 80.47.0) which is interrogated by the Branch on Overflow routine. It is important to note that the 705 overflow check indicator switch (0904) must be set to PROGRAM CONTROL for proper functioning of the simulated 650 overflow switch.

Error Switch simulation is not included in the simulation program. Error sensing is under control of the 705. All check indicator switches other than the 0904 switch are set to the AUTOMATIC position as the simulation program does not include error correction routines for 0902 and 0903 errors. Thus in the event of a 705 read-write error (0902) it is necessary to manually transfer to the appropriate instruction in the simulation program to re-read (symbolic location 7.03.0) or to re-write (symbolic location 7.84.0) the record in error, after restoring the cards as may be required. In the event of an error in card punching (0903) it is advisable to mark the error card for subsequent manual correction and resume operation.

Key Controls simulation is quite apparent. The 650 program start and program stop keys are represented by the 705 start and stop keys. The function of the 650 transfer key is accomplished by entering in the program register, at symbolic location 80.04.1 - 001, a 650 NO-OP instruction with an I-address of the 650 word to which transfer is desired, and manually transferring on the 705 to symbolic location 10.00.0. The function of the remaining keys - program reset, computer reset, accumulator reset, error reset, and error sense reset - may be simulated by entering zeros in the 705 memory positions representing the components concerned.

SIMULATION OF THE 533 CONTROL PANEL FUNCTIONS

The functions performed by the control panel of the 533 Read-Punch Unit and the input-output buffers of the 650 are accomplished in the simulation program by sequences of 705 instructions. It is obvious, therefore, that the portions of the program which simulate the control panel must be programmed to conform with the wiring of the control panel for the 650 program being run. These routines of the program, known as Read Mapping and Punch Mapping, are shown in the listing of the simulation program included in the appendix; they were written specifically for simulation of the control panel wiring for "SOAP" - Symbolic Optimum Assembly Program. Comments and suggestions concerning the programming of Read Mapping and Punch Mapping routines are included under "Notes on Programming of Read Mapping and Punch Mapping."

FUNCTIONING OF THE PROGRAM

As the appendix includes both a flow chart and a complete listing of the 650 Simulation Program, the following explanations are intended merely as a general description of the program. A list of the parts of the program by major symbolic blocks, with a brief description of the functions of each part, is provided below as a basis for discussion.

<u>MAJOR SYMBOLIC BLOCKS</u>	<u>FUNCTIONS</u>
00	Pivot Transfers and 0X Codes Routine *
01	1X Codes Routine
02	2X Codes Routine
03	3X Codes Routine
04	4X Codes Routine
06	6X Codes Routine
07	7X Codes Routine
08	Code 84 - Table Lookup
09	90 BRD Codes and Housekeeping 2
10	Interpretive Routine
11	Convert 650 Address to 705
12	UNPAC (First Part)
13	PAC
14	Convert Numeric to Alphabetic
15	Convert Alphabetic to Numeric
16 & 17	Message Buffer and Routines
19	Exit Routine for Subroutines
20	Final Stop (HLT 7777)
48	Housekeeping 1
50	Unsigned Constants
51	Signed Constants
70	Ten-Word Buffer
71	80 Column Card Buffer
80	650 Components (Storage Entry Switches, Distributor, Accumulator, Program Register, Address Register, and Overflow Register), Alpha Register, Beta Register, and Miscellaneous Constants
90-94	Read Mapping Routine
95-97	Punch Mapping Routine
98	650 Drum Memory Print-Out
99	Continuation of UNPAC

* X indicates a variable digit.

HOUSEKEEPING

Housekeeping operations of the program are accomplished in two stages: Housekeeping 1 (symbolic block 48) is actually a separate 705 program which sets up various ASU's and sets to zero most of the memory positions of the simulated 650 drum. This routine must be assembled apart from the program proper. Housekeeping 1 presumes the use of a special one-card load program supplied with the deck. The final instruction of Housekeeping 1, a transfer to 0004, returns control to this one-card load which brings the balance of the simulation program into 705 memory, thereby displacing Housekeeping 1. The "00" transfer control card of the main simulation deck contains a transfer to Housekeeping 2 which consists of the last few instructions of symbolic block 09. Here, the balance of the "drum" is set to zero, thus wiping out the load program; and entry to the Interpretive routine of the simulation program is effected.

MAIN ROUTINES

Interpretive Routine

Interpretive routine functions are primarily those of executive control and analysis of the specific 650 instructions; they constitute simulation of the internal functions of the 650. Symbolic program block 10 contains the Interpretive routine, and entry is made to its first instruction each time a 650 instruction is executed. The flow chart in the appendix illustrates the functioning of this routine in considerable detail. Instructions are moved into the program register and data into the distributor from 800X locations or from drum locations in the appropriate sequences. When instructions or data are located on the drum, the Interpretive routine utilizes the Convert 650 Address to 705 and UNPAC subroutines to fetch the information and put it in proper form. An α LOD α technique is used to enter and exit these subroutines. In addition, the Interpretive routine provides for validity checking and controls the half-cycle and address stop features. Execution of the specific 650 operation code is carried out in separate routines, transfer to which is effected through a method of digit selection on the tens and units position, in that order, of the operation code. The initial transfer of this digit selection routine using the tens position of the operation code is set up and executed in this Interpretive routine.

Pivot Transfers and 650 Operations Routines

The Interpretive routine and the Pivot Transfers constitute a double digit selection device identifying the operation code. The specific routines

for the various 650 instructions can be located readily in the program listing as the symbolic block numbers correspond to the high order digits of the operation codes.

In the case of the 6X codes, the actual 650 arithmetic operations are performed by the corresponding arithmetic (1X codes) routine in block 01; the function of symbolic block 06 is simply that of resetting the accumulator (upper accumulator only for code 64).

The 2X operations routine makes use of the Convert 650 Address to 705 and PAC subroutines in performing the five 650 Store operations.

The 3X (Shift) and 4X (Branch) functions are straightforward, utilizing only the 03 and 04 symbolic blocks, respectively, without entering any subroutines.

The 7X codes routines are found in program block 07. The Read (70) routine first reads a card into the 80 column card buffer area, and then tests to determine whether it is a 650 load card.* If it is a load card, the entire 80 columns are moved into words 1-8 of the ten-word buffer area. If it is not a load card, transfer is made to the Read Mapping routine where the 80 columns of data are revised and edited by the simulated control panel and placed in the appropriate positions of the ten-word buffer before return to the Read routine. Then by means of the Convert 650 Address to 705 and PAC subroutines, the ten words in the ten-word buffer are placed on the simulated drum one at a time. The Punch (71) routine is essentially the reverse of the above: the Convert 650 Address to 705 and UNPAC subroutines are used in moving the data into the ten-word buffer one word at a time, and the Punch Mapping routine, simulating the control panel, transposes the data into the appropriate arrangement in the 80 column card buffer before the card is written out on the 722 Card Punch or other peripheral equipment.

The Table Lookup operation (Code 84) of the 650 is simulated in program block 08. Here again the subroutines, Convert 650 Address to 705 and

* As the 12 punch which identifies load cards may appear in any card column, it may be necessary to modify the instructions at symbolic locations 07.07.0 and 07.12.0. The listing in this manual assumes the 12 punch to be in the second column as required for the "SOAP" Program. See "Notes on Programming of Read Mapping and Punch Mapping."

UNPAC, are required in performing the operation. Searching for the argument begins with the first word in the designated band of the simulated drum. Since the table arguments must be unpacked one word at a time and compared with the contents of the simulated distributor, the simulation of this 650 operation is relatively more time consuming than that of others.

The 9X operations, Branch on 8 in Distributor Position 1-10, are simulated by a relatively few (the first 13) instructions in symbolic block 09. When a branch is indicated, a portion of block 04 is used to substitute the D-address for the I-address in the program register.

SUBROUTINES

The subroutines discussed below are called for as needed by the main routines described previously. All transfers to subroutines depend on α LOD α sequences carried out in ASU 12.

Convert 650 Address to 705

This subroutine is contained in symbolic block 11 and is utilized by some of the main routines. Before the α LOD α and the transfer to this subroutine, the 650 address is loaded into ASU 04 for conversion. In the subroutine, after the conversion has been made in the manner indicated in the flow chart, the 705 address is loaded into ASU 04, where it will be picked up by the main routine which called for the conversion. Re-entry to that main routine is then effected by returning to the second instruction after the α LOD α instruction through the Subroutine Out.

PAC and UNPAC

These subroutines (PAC in program block 13, UNPAC in blocks 12 and 99) have been illustrated and briefly discussed under "Simulation of 650 Memory."

As mentioned previously, the PAC operation compresses a 650 word and its sign into seven 705 characters by placing the sign over the second digit from the left and by converting the three low-order digits to a quaternary zone representation over the third through the seventh digits. All of the simulated 650 operations which place data on the drum make use of the subroutine. Before the α LOD α and the transfer to PAC, the 650 word (ten digits) to be packed is placed in the Alpha Register. The subroutine, after making the conversion, places the packed (seven character) word in the Beta Register, and returns control to the main routine at the second instruction after the α LOD α instruction.

The function of UNPAC is the reverse of that of the PAC subroutine: UNPAC acts on the contents of the Beta Register, stripping the zones from the six low-order characters and reconverting them into the sign and the three terminal digits, and places the resulting unpacked (ten digit) word in the Alpha Register.

Convert Alphabetic to Numeric; Convert Numeric to Alphabetic

These subroutines simulate the 650 alphabetic device by converting, respectively, five 705 characters into ten digits corresponding to the 650 alphabetic code, and vice versa. They are available in the 650 Simulation Program (in symbolic blocks 15 and 14) for convenience in programming the Read Mapping and Punch Mapping routines, respectively. Each subroutine converts one word at a time; entry to either is made with an α LOD α each time a word is to be converted.

In the case of Alphabetic to Numeric conversion, the five characters considered alphabetic are placed in the five low-order positions of the Beta Register before entry to the subroutine is made. The converted word is placed in the Alpha Register by the subroutine, and re-entry to Read Mapping is effected.

To convert numeric to alphabetic the process is reversed, i.e., the ten digit numerical word is placed in the Alpha Register before conversion, and the result is found in the Beta Register after conversion. Each of these subroutines is utilized only by the related mapping routine and thus does not figure in the operation of the program unless called for by the programmer writing the mapping routines. Obviously, they are not needed if the input and the output data are entirely numerical.

Subroutine Out

This subroutine (block 19) is actually a secondary subroutine which provides for return to the main routine from all subroutines. As already explained, entering of any subroutine is preceded by an α LOD α in ASU 12. The exit from each subroutine is an automatic transfer to Subroutine Out, which simply sets up and executes the transfer instruction required for re-entry at the appropriate instruction of the main routine concerned.

OTHER ROUTINES

The remaining portions of the program require little or no discussion. A sequence of instructions in symbolic block 16 provides for setting up

and writing out the various typewriter messages. A short routine in symbolic block 98 is available at the user's option for unpacking and printing out, on the 717 printer, the contents of the simulated drum; this routine is designed as an aid in debugging the Read and Punch Mapping routines.

NOTES ON PROGRAMMING OF READ MAPPING AND PUNCH MAPPING

As noted previously, the Read Mapping and Punch Mapping routines perform the functions of control panel wiring in the 533 Read-Punch Unit. Therefore, these routines must be written to conform to the control panel wiring required for the specific 650 application which is to be run on the 705. The program listing in the appendix includes the Read and Punch Mapping routines for "SOAP" which are relatively long and involved inasmuch as the wiring of the "SOAP" control panel is quite extensive. (See 650 Programming Bulletin 1, Symbolic Optimum Assembly Programming - S.O.A.P., Form 22-6285-1, page 34, for wiring diagram) Mapping routines for other applications will usually require considerably fewer instructions.

Familiarity with both the 650 and the 705 is required of the person programming these routines. If the panel wiring to be simulated is complex, it is advisable to make a complete analysis of the control panel functions for that application in the form of a block diagram before attempting to write the routines.

Certain essential information and some suggestions are included in the following paragraphs.

AVAILABLE MEMORY AND ASU's

Approximately 1,700 positions of 705 memory are left free for the Read and Punch Mapping routines: memory positions 18,020 through 19,729. (Symbolic blocks 90-97 are available for coding.) The following list shows the status of the various 705 storage units. Note that ASU's 13, 14, and 15 are available for the mapping routines; ASU's 01 to 05 and 07 may be used also, but if their lengths are altered they must be reset after being used. Caution may have to be exercised if ASU's 01, 02, 04, or 06 are to be used in the Read Mapping or Punch Mapping routines as these ASU's are utilized in Convert Alphabetic to Numeric and Convert Numeric to Alphabetic subroutines.

<u>Storage Unit</u>	<u>Length</u>	<u>Contents</u>	<u>Functions</u>
Accumulator	Various	Various	Miscellaneous
ASU 01	1	X	Miscellaneous
ASU 02	2	XX	Miscellaneous
ASU 03	3	XXX	Miscellaneous

<u>Storage Unit</u>	<u>Length</u>	<u>Contents</u>	<u>Functions</u>
ASU 04	4	XXXX	650 and 705 Addresses
ASU 05	10	XXXXXXXXXX	Unpacked 650 words
ASU 06	2	#0	Executing ADM instructions
ASU 07	7	XXXXXXX	Packed 650 words
ASU 08	1	F	Constant
ASU 09	1	G	Constant
ASU 10	1	H	Constant
ASU 11	1	I	Constant
ASU 12	4	XXXX	α LOD α
ASU 13	-	-	Available
ASU 14	-	-	Available
ASU 15	-	-	Available

650 LOAD CARDS

If the 650 program to be simulated uses only one type of load card, the Read routine (block 07) identifies them as load cards and handles them accordingly, provided the instructions at symbolic locations 7.07.0 and 7.12.0 refer to the card column containing the 12-punch which identifies the load cards. If, however, the program uses two types of load cards, as in the case of "SOAP", it is necessary to test for the secondary load cards in the Read Mapping routine. The first nine instructions of symbolic block 90 constitute the test for secondary load cards in the "SOAP" application; the instructions at symbolic locations 90.00.2 and 90.00.7 might require modification if the sequence were used in another application also requiring two types of load cards.

SIMULATION OF THE STANDARD (80-80) BOARD

The first operation to be programmed in a Read Mapping routine simulating the 80-80 board (or any other board) is the resetting of the 10-word storage area to zeros; conversely, the first step of programming Punch Mapping is the resetting of the 80-column card storage area to blanks. One way to complete the 80-80 board simulation is to provide, in Read Mapping, for the transmission of the first ten positions of card storage to Word 1 of the 10-word storage, the next ten columns to Word 2, etc., until all 80 columns have been moved. Conversely, in Punch Mapping, provide for the transmission of Word 1 to the first 10 positions of card storage, Word 2 to the next 10 positions, etc. This approach might be

thought of as the conventional method as it is similar to the one used in the simulation of complex boards. Of course, the simplest way to accomplish the 80-80 board simulation would be to provide for the transmission of the whole 80-column card storage area at one time to words 1-8 of the 10-word storage, and vice versa. Re-entry to the Read routine from Read Mapping is at symbolic location 07.21.0, and to the Punch routine from Punch Mapping at 07.84.0.

ALPHANUMERICAL DATA

The two subroutines provided for handling alphanumerical data, Convert Alphabetic to Numeric and Convert Numeric to Alphabetic, already have been discussed in some detail. They are used in the following manner:

In Read Mapping, place the five-character alphabetic word to be converted in the Beta Register, α LOD α in ASU 12, and transfer to symbolic location 15.00.0. Upon return from symbolic block 15, the converted word may be loaded into ASU 05 from the Alpha Register and unloaded in the desired word position of the 10-word storage. Conversely, in Punch Mapping, place the 10 digit numerical-coded word in the Alpha Register, α LOD α in ASU 12, and transfer to symbolic location 14.00.0. Upon return from symbolic block 14, the converted word may be loaded into an ASU, set to five positions, from the Beta Register and unloaded in the appropriate five positions of the 80-column card storage area.

SIMULATION OF STORAGE ENTRY A-B-C, PUNCH CARD A-B-C, ETC.

When more than one card format is to be read into the simulated 650, or when more than one card format is to be punched, the programming will be facilitated by writing a separate Read Mapping and/or Punch Mapping routine for each different format, using a different symbolic block number for each routine. Entry to the appropriate routine will be dependent upon an initial test. The setting up of a control word to identify the different card formats in Read Mapping is simply a matter of testing the appropriate columns, i.e., positions of the card record, and placing 8's and 9's in word 10 in accordance with the results of the tests.

When co-selector simulation is necessary, the following technique may prove helpful:

71.00.0 with an increment of 001 is the position of card column 1 in the 80-column card storage area. Depending on whether or not

a predetermined controlling factor, such as an X punch in col. 79, is present, ASU 13 is set to a length of five and ASU 14 is set to a length of zero, or vice versa. Serial transmission is now attempted through both ASU 13 and ASU 14, as follows:

	<u>ASU</u>
RCV 70.01.0 - 009	
TMT 71.00.0 + 001	13
TMT 71.00.0 + 011	14

The ASU which is set to zero will cause the related TMT instruction to function effectively as a NOP instruction, and the other ASU permits the selected five digits to pass.

OPERATING NOTES

The information in this section is intended as a check-list for users of the 650 Simulation Program before assembling the program and as reference material for the operator during the actual running of the program.

STEPS REQUIRED TO UTILIZE THE SIMULATION PROGRAM

- A. Program the Read and Punch Mapping Routines; card punch the symbolic instruction cards and insert them in the proper sequence in the main symbolic deck.
- B. Modify symbolic instructions 07.07.0 and 07.12.0 so that the increment corresponds to the card column containing the 12-punch which identifies the 650 load cards.
- C. It may be desirable to transfer the 650 load cards and data cards to magnetic tape in an auxiliary operation and to use the tape as input for the simulation program. To modify the program for tape input, change the instruction at symbolic location 07.03.0 to "SEL 020X" and insert these three additional housekeeping instructions as class 1 symbolic entries in Housekeeping 2:

09.16.0 .	SEL	020X
09.17.0	RWD	0002
09.18.0	IOF	0000

These instructions apply to a 705 with a 754 Tape Control Unit. If tape input is desired on a 705 equipped with a 777 Tape Record Coordinator, the instructions should be in the appropriate form, and a BPC instruction should be inserted immediately following the SEL instruction located at symbolic location 07.03.0.

Another procedure which may prove useful if a 650 program is to be simulated frequently is as follows: After the 650 program has been loaded into core storage under control of the simulation program, the entire 705 memory may be written on a tape. Using this tape for subsequent runs of the program will result in a considerable saving of time. To make use of this procedure it is necessary to devise a housekeeping routine which will initialize the various ASU's and, as the final step, read in the tape record containing memory. As the last position of memory will not be present on the tape, the

housekeeping routine must provide for placing the appropriate character, an "H", in memory position 19, 999 before the Read instruction addressed to the memory tape is given. Because the housekeeping program will be wiped out when the tape is read in, it is necessary to locate the routine in memory so as to have the last instruction, i. e., the Read instruction, located at 15, 334. At the end of the Read command, MAC I will step five positions and thus will be at the appropriate place in the simulation program.

- D. If a 717 printer is available "on-line", it may be desirable to print the output instead of punching it, either while testing the Read and Punch Mapping routines, or for final output if a printed report is needed. To make this modification, simply change symbolic entry 7.84.0 to "SEL 0400". If the 650 card output is to be used for printing reports with rearrangement of the data on, for example, the 402 Accounting Machine, it will save an auxiliary listing operation to print directly on the 717 line printer. It usually will be necessary, then, to incorporate the appropriate instructions in the Punch Mapping routine to provide the desired format.
- E. Assemble Housekeeping 1 and the main program separately. (Note: In assembling the main program the operator may expect three "check operation" messages in addition to the final stop message. These messages will refer to symbolic entries 01.57.0, 01.63.0, and 08.32.0 and may be disregarded; they occur as a result of using the special technique of addressing a LNG instruction to an ASU.)
- F. Prepare 705 program cards to be used to initialize the simulated storage entry switches and simulated program register. The "patch" card for initialization of the storage entry switches should contain, in columns 16-25, the 650 instruction which is set initially in the storage entry switches when operating on an actual 650; the units position of the instruction should be signed plus. The "patch" card for initialization of the simulated program register should be punched with the following 650 instruction as data in columns 16-25: 00 0000 8000; the units position should not be signed. The actual 705 addresses to be punched in the "initial address" columns of these cards may be obtained from the assembly listing. The "number of columns" will be punched "10" in both cases. These two initialization cards must be placed in the main deck of simulation program cards immediately preceding the transfer control card.
- G. Using the assembly listing, translate the symbolic addresses of the various simulated 650 components, etc., into actual addresses so as

to have the information readily available at the console when the program is being run.

H. Arrange the cards in the card reader in the following sequence:

1. Special one-card load program
2. Housekeeping 1 cards
3. Housekeeping 1 "00" transfer control card
4. Simulation deck (main deck)
5. Storage entry switches initialization card
6. Program register initialization card
7. Simulation program "00" transfer control card
8. 650 program load cards
9. 650 program data cards

If tape input is used for the 650 load cards and data cards, the transfer control card of the simulation program will be the last card in the card reader.

METHOD OF OBTAINING A 650 "DRUM" PRINT-OUT

To obtain a print-out of the simulated 650 drum on an "on-line" 717 Printer, the operator may effect a manual transfer (705) to symbolic instruction 98.70.1, actual address, 19734. The end of the drum print will be signaled by HLT 9999. If desired, a 705 memory print-out may thereafter be obtained by placing a memory-print deck in the card reader and depressing the 705 start key, which will transfer control to a connective routine reading in, and transferring to, the memory print-out program.

READ-OUT STORAGE

READ-IN STORAGE

Contents will be written on
typewriter by transferring to
symbolic location 16.25.0.

Contents will be written on type-
writer by storing 650 drum
address at symbolic location
16.19.0 and transferring to
16.77.0.

Word (signed) to be entered on
drum is stored at symbolic lo-
cation 16.21.0. Drum address
is stored at 16.19.0 and trans-
fer is effected to 16.96.0.

LISTING OF THE 650 CONSOLE COMPONENTS VERSUS THEIR
705 COUNTERPARTS (cont'd.)

<u>650 Console Component</u>	<u>705 Simulation</u>
Overflow Switch	<div style="text-align: center;"> STOP SENSE </div> <div style="margin-top: 10px;"> OFF ON </div>
Error Switch	<div style="text-align: center;"> STOP SENSE </div> <div style="margin-top: 10px;"> Error sensing is under control of the 705. (All check indicator switches except 0904 should be set to AUTOMATIC.) </div>
Transfer Key	<div style="text-align: center;"> Enter 00 0000 XXXX in program register (symbolic location 80.04.1) and transfer to symbolic location 10.00.0 (XXXX being the address of the 650 instruction to which a transfer is desired). </div>
Program Start Key	705 Start Key
Program Stop Key	705 Stop Key
Program Reset Key	Enter zeros in simulated pro- gram register.
Computer Reset Key	Enter zeros in simulated pro- gram register, distributor and accumulator.
Accumulator Reset Key	Enter zeros in simulated dis- tributor and accumulator.
Error Sense Reset Key	Not represented

PROGRAM STOPS (705)

Special One-Card Load Program

<u>Stops</u>	<u>Explanation and Action</u>
--------------	-------------------------------

9531	Card Reader end-of-file stop: "00" card missing. Check program deck, ready "00" card in card reader, RESET, and START.
------	---

Simulation Program

<u>Stops</u>	<u>Explanation and Action</u>
--------------	-------------------------------

0913	650 Half-cycle Stop. Depress START key to continue half-cycling, or place alteration switch 0913 OFF and depress START key to run automatically.
------	--

0914	650 Address Stop. Depress START key to resume operation.
------	--

1111	End of "Display 650 Word" routine. Depress START key to display word at next higher drum address, or manually transfer to symbolic location 10.00.0 to begin, or resume, operation.
------	---

2222	End of typewriter messages. Depress START key to resume operation.
------	--

7777	End of job.
------	-------------

9999	End of 650 "drum" print-out. Place 705 memory print program MEPR 70 or MEPR 72 in card reader and depress START key for 705 memory print-out.
------	---

CHECK INDICATOR STOPS

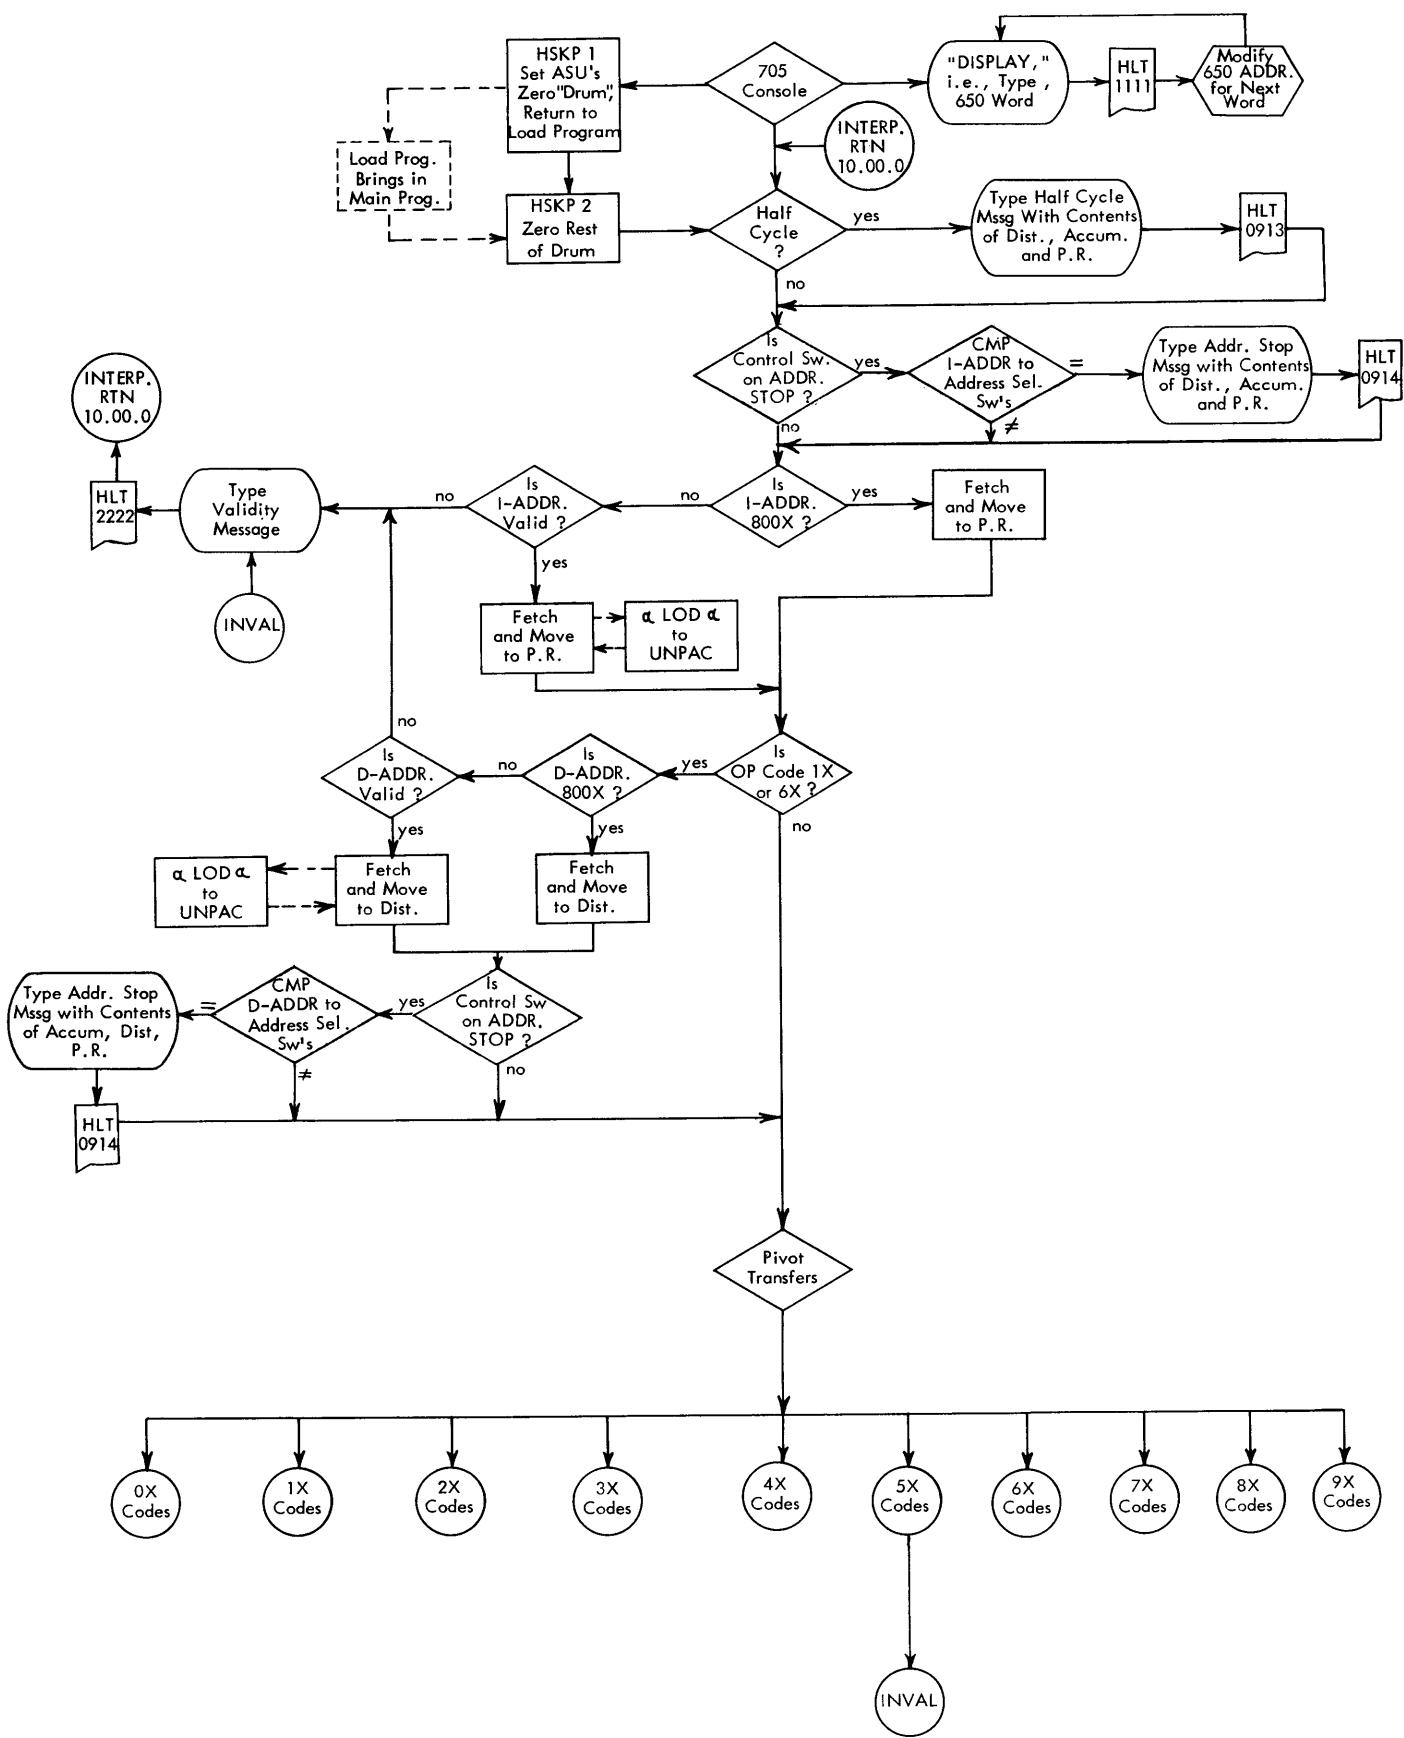

<u>Stops</u>	<u>Action</u>
0902 while reading	Remove cards from the hopper and run remaining cards out of the card reader; the error card will be the fourth card from the back. Or if end of file is about to occur, remove cards from both the hopper and the stacker, and run out the remaining cards; the error card will be the second from the front. Correct the error card, ready it and subsequent cards in the card reader, and manually transfer (705) to symbolic location 7.03.0 to re-read the record. Or if input is from tape, RESET, manually back-space the tape from the 705 console, and transfer to symbolic location 7.03.0 to reread the record.
0902 while writing	The card containing the error will be the one entering the stacker. Mark the error card and manually transfer to symbolic location 7.84.0 to rewrite the record.
0903 while writing	The card containing the error will be the top card in the stacker. Mark this card for subsequent manual correction and resume operation by depressing the START key.
