Systems Reference Library

IBM 7094 Principles of Operation

This manual provides information on the content and operation of the IBM 7094 Data Processing System. It contains detailed discussions of computer instructions, commands and orders; data channel operations, input and output components, and programming examples. In addition, comprehensive discussions are provided of general concepts, as applied to the 7094.

This manual, together with the *IBM 7094 Model II* Data Processing System bulletin, Form A22-6760, is to be used as reference material for the IBM 7094 II system. Compatibility of performance of like 7094/7094 II instructions and operations can be assured only if these instructions and operations are employed as stated herein.

FIFTH EDITION

This is a reprint of A22-6703-3 incorporating changes released in the following Technical Newsletter:

вм 7094 Data Processing System

IBM 7094 Data Processing System

The increased precision, speed, and computing versatility demanded by the physical sciences and business, have been provided in the applications-dictated івм 7094 system. It is upwardly compatible from івм 704-709-7090 systems and incorporates laboratory tested and installation proved program support. The solid state 7094, with its real-time data transmission features and mass storage facilities, is the computing answer to the new challenges of science and industry.

System Fundamentals

The IBM 7094 Data Processing System is compatible with the IBM 7090 Data Processing System but has substantially increased internal operating speeds. Improvements in the processing unit include faster execution of:

Floating-Point Operations Fixed-Point Multiply and Divide Operations Index Transfer Instructions Conditional Transfer Instructions Compare Operations

The basic core storage operating cycle is 2 microseconds per word read from or written into core storage. Where possible, two instructions are transferred simultaneously from core storage to the processing unit, greatly reducing the number of instruction cycles. In addition to increased speed, the IBM 7094 Data Processing System offers these new or expanded functions:

Fast Double-Precision Floating-Point Arithmetic Seven Index Registers

New Index Complementing Instructions

Functional characteristics of 7094 system components remain unchanged from those of the 7090 system. Except for the 20 additional instructions on the 7094, compatibility exists between the 7090 and 7094 systems. All 7090 programs with properly defined instructions can be executed on a 7094 system in the same manner as on a 7090, but at increased operating speed if the configuration of input-output units is the same.

Core Storage

The IBM 7302 Core Storage has a capacity of 32,768 words (Figure 1). Each word is comprised of 36 databits. When data are taken from or entered into a word location, reference must be made to this address.

The 36 bits of a word are used in two ways: as an instruction to the computer "ordering" a particular operation, or as the operand of an operation (data).

Stored Program

The computer does its work by executing many instructions at high speed. The set of instructions used in solving a problem form a program for the computer. Because the computer holds its instructions internally it is called a stored program system.

Normally, instructions are taken from sequentially ascending locations. However, the execution of instructions does not have to occur in this manner. It is possible, by using control or transfer instructions, to alter the sequential execution process and to indicate some other location as the next instruction to be executed. In this way, it is possible to repeat any instruction or block of instructions as often as desired.

The logical path followed by the program may be determined by a series of tests applied at points in the execution process, thus providing a stored program with the ability to control its own course of execution.

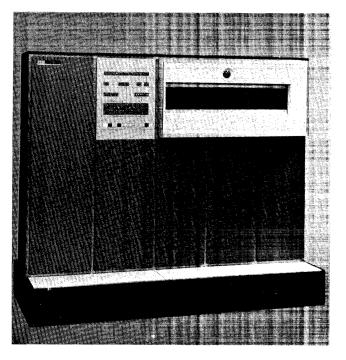

Figure 1. IBM 7302 Core Storage

Fixed-Point Numbers

When a word contains a fixed-point number, the first of the 36 positions holds the algebraic sign of the number. A "0" signifies a positive number and a "1" signifies a negative number. The remaining 35 positions contain the magnitude of the number. Figure 2 shows locations in storage containing plus one and minus three. When fixed-point operations are used, the programmer must decide where the point is to be located. On the computer, the point which separates the integral part from the fraction part is termed a binary point.

Figure 2. Words Containing +1 and -3

Floating-Point Numbers

When the range of numbers anticipated during a calculation is either large or unpredictable, it becomes difficult to work with fixed-point instructions. An alternative set of floating-point instructions is available for such calculations. These instructions maintain the binary point automatically.

A floating-point decimal number X may be expressed as a signed proper fraction (N) multiplied by some integral power (n) of 10. The number is normal if the power of 10 (n) is chosen so that the decimal point is positioned to the left of the most significant digit of N. Examples:

\boldsymbol{X}		N		10 ⁿ
010	_	10	×	10-
.140	==	.14	\times	10°
4.600	=	.46	\times	10 ¹
88.000		.88	\times	10 ²

Likewise, a floating-point binary number (X) may be represented as a signed proper fraction (B) times some integral power (b) of 2. In the normalized case the binary point is positioned to the left of the most significant digit of B. Examples:

X(BINARY)		B(BINARY)	2 ^b ((DECIMA	AL)
001		100	×	2-2	
.100	=	.100	X	20	
1.100		.110	X	2^{1}	
110.000		.110	×	23	

In the computer a floating-point number is stored in a word as shown in Figure 3. The fraction is contained in bit positions 9 through 35. A floating-point

Figure 3. Floating-Point Word Format, Single Precision

number with a 1-bit in position 9 is said to be normal. The sign of the fraction is contained in the S position of the word. The characteristic is formed by adding +128 to the exponent. For example, an exponent of -32 would be represented by a characteristic of 128 - 32 or 96. An exponent of +100 would be represented by a characteristic of 100 + 128 or 228. Since $128_{10} = 200_8$, the characteristic of a nonnegative exponent always has a 1-bit in position 1, while the characteristic of a negative exponent always produces a 0-bit in position 1. A normal zero has no bits in both the characteristic and the fraction.

Instructions

Most computer instructions have an address part which is used to denote the location in core storage which is to be subjected to some arithmetic or logical operation. This address part or field always occupies bit positions 21 through 35 (Figure 4). The 15-bit address field is just large enough to hold the number 32,767, the highest core storage address. This number, expressed in binary, is simply 15 consecutive ones.

Figure 4. Address Part of the Instruction

The operation part of an instruction, in general, is not fixed in length but may vary from one instruction to another. Figure 5 shows the bit pattern for the ADD instruction specifying core location 0001.

Figure 5. Add Instruction

Central Processing Unit

The central processing function is performed by the IBM 7109 Arithmetic Sequence Unit and the IBM 7110 Instruction Processing Unit. All arithmetic and instruction control functions are accomplished by these units. For ease of description, these units are called the central processing unit (CPU) (Figure 6).

The registers, counters, indicators, and switches within the CPU are described under "Central Processing Information Flow."

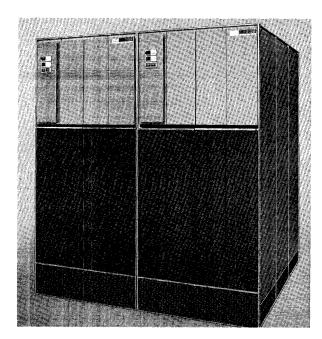

Figure 6. Central Processing Unit

Indicators and Sense Devices

Three indicators in the CPU are either on or off and can be tested by a test instruction peculiar to that indicator.

The accumulator overflow indicator is turned on whenever a 1 passes into or through position P from position 1 of the AC as a result of the execution of a fixed-point arithmetic or a shifting instruction. An example is a carry resulting from an algebraic addition. Either of the instructions TRANSFER ON OVERFLOW or transfer on no overflow can be used to test the status of this indicator.

The divide-check indicator is turned on, in fixedpoint division, if the magnitude of the number in the AC (dividend) is greater than or equal to the magnitude of the number in storage (divisor). In floatingpoint division a divide check occurs only when the divisor is zero or if the magnitude of the fraction of the dividend is greater than or equal to twice the magnitude of the fraction of the divisor. The dividecheck indicator is tested by the DIVIDE CHECK TEST instruction.

The input-output check indicator (1-0 check) is turned on by the attempted execution of an inputoutput instruction (copy, locate drum address, reset and load channel, or load channel) without selecting an input-output unit. Other conditions affecting the status of this indicator are discussed in the following pages. The 1-0 check indicator is tested by the INPUT-OUTPUT TEST instruction.

Transfer Trap Mode

The computer can be operated in a special transfer trap mode. The major use of this mode is in program testing. Operation in the trap mode permits the program to run at normal speed with interruptions of normal operation only at transfer points. At such points the location of the last sequential instruction is saved, and a transfer of control is made to a fixed location. Beginning at this fixed location, a special monitoring program may aid the programmer in control of his stored program even in the event of an incorrect transfer.

When the computer is operating in this mode, the location of each transfer instruction replaces the address part of core storage location 00000 before the instruction is executed. All functions of the transfer instruction (index register modification, testing, etc.) are performed normally. However, program control is transferred to location 00001 for all unconditional transfer instructions and conditional transfer instructions for which the transfer conditions are met.

Two instructions, trap transfer (TTR) and enter storage nullification and transfer (ESNT), are immune to the trapping mode. Their locations are never stored in location 00000, and control is always transferred to the location specified by the address of these instruc-

The instructions enter trapping mode and Leave TRAPPING MODE are used to enter or leave this special mode. Depression of the clear or reset keys on the console also causes the computer to exit from this mode.

Sense Switches

Located on the console are six sense switches, each of which may be turned on or off by the machine operator. The instruction swr (switch test) is used to test the setting of any desired switch.

Sense Lights

Also located on the console are four sense lights. Any one of these lights may be turned on or off by the SLN and SLF instructions. Another instruction, SLT (sense light test) is used to test the status of any desired sense light. The sLF instruction will turn off all sense lights.

Panel In-Out Switches

A group of 36 switches corresponding to the 36 positions of a word are provided on the console. A switch turned down corresponds to a 1, and one turned up corresponds to a 0. The instruction enter keys causes the number entered into these switches to replace the contents of the MQ register. A reset switch on the 7151 restores all input switches to the zero state.

Address Modification with Index Registers

One of the primary uses of index registers arises from their ability to modify instruction addresses. For this to occur, the instruction must specify the particular register that is to take part in the modifying activity. This is done by placing the appropriate bit configuration in the tag field (bit positions 18-20) of the instruction.

The 7094 has seven index registers and provides program compatibility with the three index registers used on the 7090. Index registers A, B, and C are used in 7090 index compatibility mode. Index register tag coding is:

INDEX 18	TAG 19	POSITION 20	INDEX REGISTER
0	0	1	A (XR 1)
0	Į	0	B (XR 2)
0	l	1	D (XR 3)
1	0	0	$\mathbf{C} (\mathbf{XR4})$
1	0	1	E (XR 5)
1	1	0	$\mathbf{F} (\mathbf{XR6})$
1	1	1	G (XR 7)

The seven index registers use all combinations of these tag bits for individual addresses; the presence of two or three tag bits does not mean multiple index registers are being used unless the 7094 is operating in the 7090 index compatibility mode. Compatibility with existing 7090 programs, which use multiple tags, is provided by two multiple tag instructions for entering and leaving multiple tag mode.

The assignment of the appropriate bit configuration in the tag field selects the index register to be used in the modifying activity. The instruction is then executed as if its address field contained the stated address minus the contents of the index register. For example, assume that storage location 01000 contains the instruction ADD 02117 and that this instruction has a 2 in its tag field. If the contents of index register 2 are 117, the number stored in location 02000 (2117 minus 117) is added into the accumulator when the ADD instruction is executed. However, location 01000 still contains the instruction ADD 2117 in its original form. Address 02000 is called the effective address, and the process is called effective address modification; that is, the address of the instruction is modified in the CPU for execution purposes but is unaltered in storage.

All computer instructions, when tagged, are subject to effective address modifications with the following exceptions:

- 1. Instructions which load, store, modify, or test the contents of an index register. These instructions use the tag field to specify the index register which is to be affected.
- 2. Convert instructions.

3. Those sense indicator instructions which combine the address and tag fields and use the entire right half of the instruction as a *mask*.

Note: The convert and sense indicator instructions referred to in items 2 and 3 above are defined in the section "Computer Instructions."

Multiple Tagging of Index Registers

In the 7094, an instruction involved in index register operation may refer to more than one index register, provided the following conditions exist:

- 1. The 7094 is operating in multiple tag mode.
- 2. The index registers used in multiple tagging are restricted to index registers 1, 2, and 4 (Figure 7).

Multiple tagging permits instructions using index registers to use information stored in up to three index registers simultaneously. This multiple usage has extensive application; however, care must be exercised when multiple tags are used. The use of multiple tags results in a logical or (See "Logical Operations") of the contents of the specified index registers.

For example, if a tag of 3 (bit configuration 011 in bit positions 18-20 of the using instruction—7094 operating in multiple tag mode) is given, the 15 bit positions of index register 1 (xr 1) are or'ed with the 15 bit positions of index register 2 (xr 2).

NOTE: If the 7094 was not operating in multiple tag mode, the above bit configuration would result in referring to the contents of index register 3 (xr 3).

Assume that xr 1 contains the number 03204_8 (000 011 010 000 100) and xr 2 contains the number 03061_8 (000 011 000 110 001). An instruction, ADD 06521_8 , with a tag of 3 will cause index register

+	04008		38	06521 ₈
S. 1	11	12 13 14	17 18 20 3	21 35

operation on the contents of the two index registers (xr 1 and xr 2) as follows:

xr 1	000 011	010 000	100	(03204_8)
xr 2	000 011	000 110	001	(03061_8)
Inclusive or'ed result	000 011	010 110	101	(03265_8)

The or'ed result (03265_8) is subtracted from the address contained in the ADD instruction $(06521_8) = 03234_8$, which becomes the effective address that the ADD instruction uses instead of 06521_8 .

Note that the contents of the two index registers involved, xr 1 and xr 2, do not change their contents (xr 1-03204g, xr 2-03061g) during the oring operation. However, if multiple tagging is used with instructions that normally alter the contents of the index registers (TIX, TXI, etc.), both index registers would contain the or'ed result.

In 7094 operating mode, multiple tag operations are not performed when more than one bit is in the tag field.

Tag F	ield		
Binary	Octal	Index Registers	Specified
000	0	None	
001	1	A	1
010	2	В	2
011	3	A & B	1 & 2
100	4	С	4
101	5	A & C	1 & 4
110	6	B & C	2 & 4
111	7	A & B & C	1 & 2 & 4

Figure 7. Multiple Tags

Decrement Field

A group of instructions are used to test or alter the contents of an index register. The value used to test or alter an index register is contained in positions 3-17 of these instructions. These 15 bit positions are referred to as the decrement field (Figure 8).

Complement Arithmetic

When index registers are used for effective address modification, the contents of an index register are always subtracted from an instruction's address. Since neither the address of an instruction nor the contents of an index register are associated with any algebraic sign, it is not possible to accomplish effective address modification by addition in any direct manner. However, this may be accomplished by using complement arithmetic. The following definitions apply to this type of arithmetic:

- 1. The 1's complement of a number is defined as that number which results by replacing each 1 in a number with a 0 and each 0 with a 1. For example, given the binary number 101, the 1's complement would be 010. Also, the sum of a binary number and its I's complement is a binary number composed of all ones (101 + 010 = 111).
- 2. The 2's complement of a binary number is defined as the 1's complement of a number increased by one. Thus, for the preceding example, the 2's complement of the binary number 101 would be 011.

Effective Addresses

Effective addresses are always formed in the computer by the addition of the 2's complement of the contents of the index register. This is an automatic feature. For example, if index register 4 contains the number 00005₈ and the instruction ADD 00015₈ with a tag of 4 is executed, the effective address is 00010:

2's complement of XR 4	111	111	111	111	011
ADD instruction address	000	000	000	001	101
Effective address (carry lost)	000	000	000	001	000

Since both the contents of an index register and an instruction address are 15-bit numbers, all resulting carries to the sixteenth position will be lost.

If index register 4 had contained the 2's complement of 00005₈ (77773₈) then the effective address would be 00022.:

2's complement of XR 4 000 000 000 101 ADD instruction address Effective address 000 000 000 010 010

Note: All numbers (addresses) in this manual are expressed in octal notation unless specifically noted otherwise. Binary numbers are readily apparent.

Indirect Addressing

The concept of effective address modification is extended for a large group of instructions for which indirect addressing is provided. This extension is carried out as follows:

- 1. Just as index registers are addressed with a tag, indirect addressing is specified or "addressed" by a flag (1 bits in both positions 12 and 13 of the instruction). An effective address is computed by subtracting the contents of the specified index register (if one is specified) from the address part of the instruction. This is known as an indirect effective address.
- 2. The contents of this indirect effective address are examined, and the index register specified by this location and the address part of this location are used to compute a direct effective address. The instruction is then executed as if its address field had contained this direct effective address with no flag or tag.

The following examples illustrate this process. Assume that the address part of core storage location 00054 contains 00273. If the instruction ADD 00054 is executed, the contents of core storage location 00054 are added to the contents of the accumulator register. However, if this same instruction had indirect addressing specified by 1 bits in both positions 12 and 13, the contents of location 00273 would be added to the accumulator. Now assume that index register 1 contains 00004 and core storage location 00050 contains a I in its tag field and 00167 in its address part. If the instruction ADD 00054 (with an index tag of 1 and indirect addressing specified) is executed, then the indirect effective address equals 00050 (address field of the ADD instruction minus the contents of XR 1). The direct effective address is 00163 (00167-00004) and the contents of this location are added into the contents of the accumulator.

Data Channels

Both the IBM 7607 and 7909 Data Channels of the 7094 Data Processing System use a command word technique for data transmission. With this technique, control of an input-output operation passes from the central processing unit to the data channel itself, freeing the central processing unit to proceed with its own stored program. The command word is used to transfer control, and the data channels contain registers and counters to exercise this control. The channel performs command decoding, word counting, address changing, assembly of data bytes into words, and disassembly of words into bytes.

The 7909 Data Channel attaches to the IBM 7606 Multiplexor, as does the 7607 Data Channel, and controls data transmission between the IBM 7631 File Control, the IBM 7640 Hypertape Control, and the 7094 system. In addition, the 7909 can also instruct and select the 7631 and perform limited counting and testing operations independently of the CPU or of activity of other data channels. This represents a significant departure from operation of the 7607 Data Channel.

With a suitable program, it is possible to perform data transmission in storage (core-to-core or disk-to-disk on the same 7909) independently of CPU activity. The channel may also perform independently a limited search of information in core storage or on the disk storage. Although channel operation is asynchronous and independent of the CPU, the CPU is able to supervise 7909 operation. The CPU may interrogate, start, and reset the channel by using the proper CPU instruction. In addition, the 7909 may signal the CPU by means of a channel trap command.

Data Channel Operation

Data being transmitted between core storage and any input-output device must pass through a data channel. The operation of a data channel is initiated by the execution of two instructions in the central processing unit. Once started, the channel operates independently of the main program being executed by the CPU. A data channel has the responsibility for controlling the quantity and destination of all data transmitted between core storage and the input-output device. It also performs limited counting and testing operations concerned with the transmission of data.

The IBM 7909 Data Channel is also able to instruct and select a control unit, such as the IBM 7631 File Control or the IBM 7640 Hypertape Control.

Programs for a channel operation are stored in core storage just as are instructions executed by the CPU. To distinguish between CPU and data channel programs, data executed in the CPU are termed *instructions*, data executed by the data channel are termed *commands*, and data executed by the adapter are termed *orders*.

Although a channel, once started, operates asynchronously, the main program may exercise a large degree of supervisory control through instructions

which test the status of a data channel. A single command may transmit a large block of words between core storage and an input-output device so that normally many instructions in the main program may be executed during the time taken to execute just one command in a data channel.

All transmission is in 36-bit word parallel fashion. Since the CPU and a data channel cannot take a storage reference cycle at the same time, the execution of an instruction in the main program may be delayed at least one computer cycle. Once such a delay occurs, all of the time needs of all data channels will be satisfied before the main program execution is resumed. Such delays are imposed automatically and do not interfere with the internal registers or calculations in the CPU. If the instruction being executed is not using core storage when a channel requires a storage cycle, normally no delay is occasioned. When several data channels require storage cycles at one time, the sequence of transmission is handled automatically.

A data channel controls all input-output units attached to it in much the same way. Because of the importance of magnetic tape, the relationship between a data channel and tape is discussed here. A description of the operation of the card reader, card punch, and printer, together with additional information on magnetic tape, will be found in the section "Input-Output Components."

Magnetic Tape and Data Channel (7607) Addresses

A maximum of ten IBM 729 Magnetic Tape Units per 7607 Data Channel may be used with the 7094 system. Like locations in core storage, each tape unit has an address. Each data channel also has an address. The combination of the two addresses will then specify a particular tape unit attached to a particular data channel.

To start a tape unit for reading or writing, a select instruction must be executed in the main program. The instruction READ SELECT prepares the tape for a reading operation and the instruction write select prepares it for writing. The joint address of a tape unit and data channel occupies the address part (positions 21-35) of the select instruction. If the address field of this instruction is viewed as a five-digit octal number, then the three low-order digits specify the tape unit, and the fourth and fifth digits the data channel (Figure 9).

Figure 9. Select Instruction Address Field

The specific numerical addressing system used by the tapes is as follows:

- 1. Data channels A through H are identified by the octal numbers 1 through 10 and occupy positions 23-26 of the instruction.
- 2. In the BCD mode, tape units 1-10 are identified by the octal numbers 201-212, occupying positions 27-35 of the instruction.
- 3. In the binary mode, the tape units are identified by the octal numbers 221-232 which occupy positions 27-35 of the instruction.

Examples: If the instruction READ SELECT 1201 is executed, tape unit 1 attached to data channel A will be selected and started for a reading operation in the BCD mode. If the instruction write select 3223 is given, tape unit 3 attached to data channel C will be selected and started for a write operation in the binary mode.

Data Channel Registers (7607)

Once the select instruction has been executed, the operation of the tape and transmission of data between core storage and tape are under control of the data channel. There are four registers in the channel which control its operation. These registers are similar in function to the control registers in the CPU.

The first command of a data channel program must be sent to the channel by a RESET AND LOAD CHANNEL instruction from the main program. The address part of this instruction specifies the location in core storage containing the data channel command. When this instruction is executed, the contents of the location in core storage (specified by the RESET AND LOAD CHAN-NEL instruction) are sent to the data channel control registers.

There is a separate RESET AND LOAD CHANNEL instruction for each data channel. Where select instructions specify the appropriate data channel through usage of part of their address field, the address field of the reset and load channel is fully occupied by the storage address of the command. Thus, the distinction between data channels is made in the operation part of the instruction.

Word Counter. The contents of positions 3-17 of the data channel command are loaded into this counter (Figure 10). This counter specifies the number of words to be transmitted between core storage and the input-output unit. As each word is entered or taken from core storage, the contents of the word counter are reduced by one. Once the word counter reaches zero, no more words can be transmitted until a new command puts another word count into the word counter.

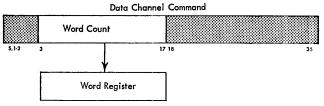

Figure 10. Data Channel Word Counter

Channel Address Counter. The contents of positions 21-35 of the data channel command are loaded into this counter (Figure 11). The counter specifies the location in core storage from which the data are to be taken during writing or to be entered into during reading. The contents of this counter are increased by one after each word transmission to or from core storage. Thus, the address counter directs the transmission of data into or from consecutive locations in core storage.

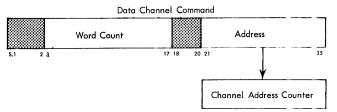

Figure 11. Data Channel Address Counter

Location Counter. This counter is similar to the instruction counter in the CPU. The location counter contains the location of the current data channel command, plus one. Thus, data channel commands are taken normally from sequential locations in core storage. Just as control or transfer instructions alter the contents of the CPU's instruction counter, transfer commands change the contents of the location counter in a data channel.

The size of these counters (word counter, channel address counter, and location counter) is set at 15-bit length. Each counter has a capacity large enough to hold the address of the last location in core storage. When a 15-bit command field is loaded into a channel counter, the leftmost bits which exceed the capacity of the counter are ignored. When the contents of a channel counter are stored in a 15-bit field in core storage, the leftmost bits corresponding to the absent bits of the register are set to zeros.

With reference to blocks of consecutively located commands or data words, the highest location in core storage and location zero are treated as consecutive

Operation Register. This register is similar to the instruction register in the CPU. The contents of positions S, 1, 2, and 19 of a data channel command are loaded into this register (Figure 12). Bit positions S, 1, and 2 provide for eight possible data channel operations. Each of the eight commands may accomplish either reading or writing. Position 19 is used only for reading operations; it has no effect on writing operations. When this position contains a 1, all functions proceed normally except that no transmission

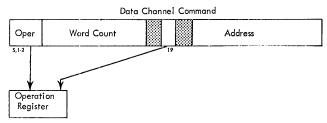

Figure 12. Data Channel Operation Register

of data to core storage occurs. Thus, a command with position 19 containing a 1 may be used to skip over a number of words (determined by the word count) while reading from an input device. When position 19 contains a 1, the data channel involved is said to be operating in the non-transmitting mode.

Data Register. This 36-bit register serves as a buffer between core storage and an input-output device.

Cale Exit-Entry. To punch or print the 72 possible positions for a row of information, two separate words must be brought from core storage. These words are stored in the 72-position exit-entry register because all punch or print magnets must be energized at about the same time. At the proper time, all 72 positions are sent to the output device being used.

Tape Register. Tape words coming from the data register are transmitted in parallel. Likewise, words going to the data register from the tape register are sent in parallel. Words going to and from the tape unit must, however, go in six-bit groups. In writing a word on tape, the word is first sent from the data register to the tape register and is then sent to the tape unit, six bits at a time. After the first six-bit group has been sent to the tape unit, the contents of the tape register are shifted six positions to the left. This process is repeated six times until the entire word has been written on tape. In the case of reading, groups enter from the right of the tape register and are shifted left until a full word has been assembled.

Data Channel Entry Keys. These keys are similar in action to the console entry keys on the CPU. There is one set on each data channel console.

Data flow for the 7607 is shown in Figure 13.

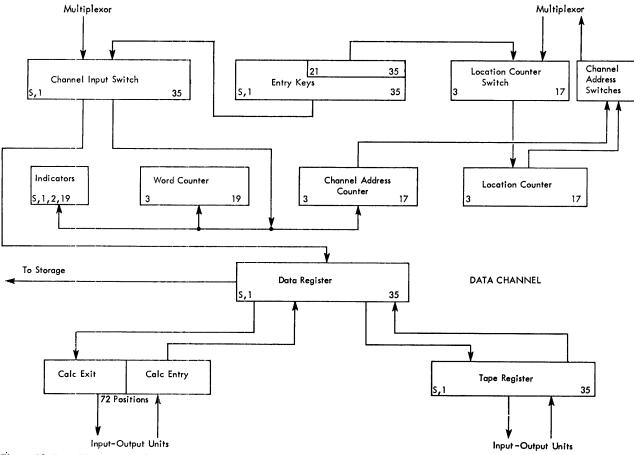

Figure 13. Data Flow, IBM 7607 Data Channel

Data Channel Register Example. An example is shown in Figure 14. If core storage location 1546 contains the data channel command, represented here as an octal number, 000124002117, and the instruction reset and load channel A with an address of 1546 is executed, then zeros will be placed in the operation register, 00124 will be placed in the word counter, 2117 will be placed in the channel address counter, and the location counter will contain 1547.

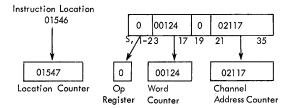

Figure 14. Data Channel Register Example

Once a tape unit has been started by a select instruction, the data channel must receive its first command within a definite time period. Thus, the reset and load channel must be executed by the main program within this allotted time period following the select order. Specific tape timings are given in the magnetic tape section of "Input-Output Components."

If the reset and load channel is not executed within the allotted time period, the tape unit is logically disconnected from the calculator and no word transmission will occur. If a reset and load channel is given at any time when an input-output device is not logically connected to the data channel, the instruction is executed in the CPU but a special indicator, called the input-output check indicator, is turned on. The status of this indicator may be tested by the stored program.

Exact description, together with examples, of the data channel commands is found in the "Computer Instructions" section.

Data Channel Indicators (7607)

Each data channel has four indicators that may be turned on during tape operations. These indicators may be tested for the on condition. When tested, an indicator that is on is turned off.

Tape Check Indicator. The tape check indicator may be turned on at any time during a tape read or write operation. When on, the indicator signals that an error has occurred in a read or write operation. The indicator will not be turned on unless the channel is logically connected to the CPU. For example, if the tape has been logically disconnected from the computer and is spacing to the next end-of-record gap, the indicator will not be turned on if an error is sensed during this period.

Beginning-of-Tape Indicator. Small strips of adhesive aluminum material are placed a few feet from each end of the tape. These strips are used to indicate the beginning of tape (load point) and the physical end of usable tape. Any instruction which backspaces the tape to its load point or attempts to backspace the tape beyond its load point turns on the beginning-oftape indicator in the data channel to which the tape is attached, indicating that the backspace instruction was not logically completed.

End-of-Tape Indicator. When the strip marking the end of tape is reached during writing, the end-of-tape indicator in the data channel to which the tape is attached is turned on. No interruption in the writing process occurs so that the writing operation may be completed even though the end-of-tape strip has been passed over. However, if the status of the indicator is ignored and writing continues, the tape may eventually be pulled from its reel. This indicator is never turned on during a read operation.

End-of-File Indicator. The end-of-file indicator in a channel will be turned on any time an end of file (tape mark) is encountered during a reading operation. An end of file may be written on a tape at any time by the write end of file (wef) instruction. The indicator is not turned on when an end of file is written.

The indicators for tape check, end of file, beginning and end of tape may be turned on by any of the tape units attached to a given data channel. To make a meaningful test of the indicators, therefore, the stored program should know which of the attached tape units had the possibility of turning on an indicator. The data channel's end-of-file indicator may also be turned on by a card reader attached to that channel.

In addition to the instructions which test the status of the indicators defined above, each data channel has a set of instructions which facilitate the synchronous operation of a stored program and its associated inputoutput activity. Two of these instructions test whether or not a channel operation is still in process. By the execution of another instruction it is possible to obtain, at any time, the contents of the data channel's operation register, channel address register, and location register.

When an end-of-file is sensed during reading, the turning on of the channel's end-of-file indicator logically disconnects the input-output device from the data channel. The execution of the channel command is terminated immediately, even if it has not

been completed. The internal registers of the data channel are not reset. By obtaining the status of the location register and the address register, the main program may always ascertain the point at which the end-of-file condition interrupted the input-output operation.

Data Channel Trap

This feature allows the data channel to signal or interrupt processing by trapping the computer program. The trap may be initiated by: (1) the completion of a channel command, (2) an end of file, or (3) a redundancy tape check. These conditions are called channel signals.

Two instructions, ENABLE (ENB) and RESTORE CHANNEL TRAPS (RCT), are used with this feature and are described in the "Computer Instructions" section.

A trap indicator on the operator's console indicates when a trap occurs. The execution of an enable or restore channel trap instruction will turn the indicator on. The execution of any trap will turn the indicator off. With the indicator off, traps are said to be inhibited.

A data channel is *enabled* by use of the enable instruction. This instruction conditions the channel so that a channel signal may be combined with it, when and if it occurs. When a channel is enabled for a particular channel signal (for example, redundancy tape check), the other channel signals are not used

for trapping. Thus, the channel is said to be *disabled* with regard to these other channel signals. A logic flow chart of circuits involved with one data channel is shown in Figure 15. Note that the trap control indicator must be on for a trap to occur.

Data channels may be individually or collectively prevented from causing traps until the program is able to handle them. In this event the channel signal is saved until the program allows it to become effective.

When a trap occurs, the contents of the instruction counter (1C) are stored and the next instruction is taken from a fixed location as follows:

HANNEL	STORE THE IC AT	NEXT INSTRUCTION FROM
Α	0012	0013
В	0014	0015
č	0016	0017
D	0020	0021
Ē	0022	0023
F	0024	0025
Ğ	0026	0027
H	0030	0031

The first instruction after execution of a trap should be an unconditional transfer. If these instructions, located at the odd locations 0013-0031, are not provided by the programmer and do not alter the contents of the instruction counter, the program resumes from the point at which the trap occurred (after executing the instruction at the odd location). A trapping signal occurs under the conditions listed below:

1. If an ioct, iort, or iost is used and no load channel instruction is waiting in the main program

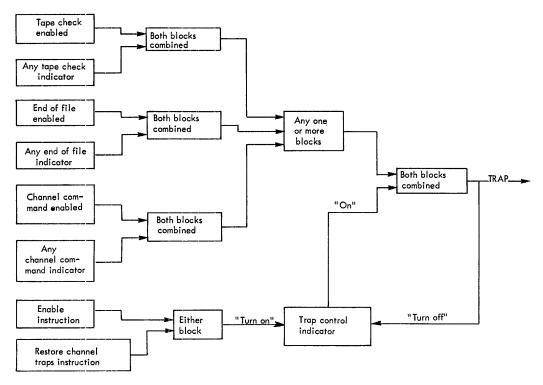

Figure 15. Logic Flow of Data Channel Trapping

- upon completion of the command. A trap resulting from this condition will cause the decrement of the location in which the contents of the instruction counter are stored to be cleared and a I to be placed in position 17.
- 2. Whenever the end-of-file indicator is turned on. A trap resulting from this condition will cause the decrement of the location in which the contents of the instruction counter are stored to be cleared and a 1 to be placed in position 15.
- 3. Whenever a redundancy check occurs. With this type of trap, the decrement of the location in which the instruction counter is stored is cleared and a 1 is placed in position 16.

If a trapping signal is generated while a channel is disabled or inhibited, the trap request is remembered until the channel is enabled or restored.

The instruction following an enable, restore channel trap, or execute instruction will always be executed before another trap is processed. Furthermore, traps are prevented from occurring between a read or write select and the following (normally a reset and load) instruction.

Execution of certain instructions, while a channel is disabled, will cause the remembered trap to be lost. This type of trap and the effect it produces are as foll

ollows:	
TYPE	EFFECT
Channel command	Read or write selection of the corresponding channel
End-of-file	Execution of a transfer on end-of-file for that channel
Tape check	Execution of a transfer on tape-check for that channel

A TEF or TRC instruction, to a disabled channel, will reset the EOF or tape check indicator and will be executed properly.

The end-of-file and tape-check indicators are turned off whenever a trap results from an indicator's being on. If the tape-check indicator is on for an enabled channel (even though traps are inhibited), the channel is immediately disconnected.

When a channel is enabled for a tape-check or endof-file condition, a transfer-on-redundancy-check or end-of-file instruction addressing that channel will be treated as a no-operation instruction.

If a trap is called for, subsequent to the execution of certain halt instructions, the following procedure occurs:

1. Halt and transfer. The trap is performed and the CPU resumes execution of instructions. At the time the trap occurs, the instruction counter contains the location of the HTR instruction.

- 2. Halt and proceed. This is the same procedure as HTR except that the instruction counter contains the location of the HPR instruction plus one.
- 3. Divide or halt. The computer is restarted as with the HTR, except that the instruction counter contains the location of the divide instruction plus one.

A trap normally occurs at the completion of the instruction being executed. For example, if a trap is called for while execution of a load-channel instruction is being delayed (command is incomplete), the trap does not occur until the load-channel instruction has been completed. If a trap is called for while the CPU is in manual status, no trap occurs until the CPU is returned to automatic status. The start key need not be depressed.

The reduced cycle time of the 7094, together with instruction overlap operations, allows the 7094 to channel trap at different instruction locations than would have been experienced for the same trapping conditions on the 7090 system. In addition, variations in cable lengths between the central processing unit and the various data channels can also result in differences in trapping locations.

Caution should be exercised when programming if an attempt is made to synchronize the central processing unit and the several data channels. Allowance of sufficient instruction cycle time, following an enable (ENB) instruction, should be provided.

On a 7094, if conditions for a trap exist when the ENB is given, the instruction following the ENB will always be executed. In the event this instruction is a one cycle instruction, a second instruction may also be executed, depending on the time loss due to cable length between the CPU and the particular data channel involved in the trapping activity.

Instructions with a duration of two or more cycles provide sufficient time for the channel trap to occur with the exception of instructions that normally block channel trap, as well as the compare instructions, LAS and CAS.

Data Channel Trap Programming

For programs utilizing data channel trap, certain characteristics of the feature make some programming techniques dangerous. If these techniques are used in a program operating with data channel trap enabled, random failures may occur which appear to be machine malfunction. Usually these failures are not reproducible, owing to the random occurrence of the 1-0 interrupts. Some techniques to be avoided are:

1. Execution of TRCX or TEFX instructions, when the 1-0 interrupts are disabled, turn off the corresponding trap indicator if it is on, causing a waiting trap to be lost. If the indicator was on for either of these conditions the instruction transfers correctly. Care must be taken when testing these conditions, both in and out of the trap mode. A separate error checking routine should be used for operating in each mode, since conditions are different in both modes of operation.

2. Execution of TCOX* does not guarantee that a channel is not busy upon release. If interruption occurs because of a condition sensed at I-time of the TCOX, the channel is disconnected, causing the TCOX to advance the instruction counter to the next location following the TCOX. The interrupt now occurs, as the instruction is complete. If the interrupt routine reinitiates 1-0 activity on the channel (to maintain highest possible 1-0 speed), the channel is busy upon re-entry, but the TCOX has been bypassed. If an I-O operation follows the TCOX, its execution may cause the trap normally resulting from the previous channel activity to be dropped, also possibly causing the program to hang up in a waiting loop. It is suggested that a storage flag be kept for each channel to indicate channel activity. This flag may be tested in a:

Loop to act as pseudo-rcox* delay. The flag must be set to zero by the trap routine and set to non-zero by any routine which executes a select on the channel.

3. No data cell common to both trap and non-trap routines should be changed by the non-trap routine without disabling the interrupt system, unless the cell may be modified by one and only one instruction. This is illustrated by the following program which violates the above rule:

TRAP CLA BETA
ADD ONE
STO BETA
....restore AC
....
NONTRP CLA BETA
SUB ONE
STO BETA

If a trap occurs between NONTRP and NONTRP +2, the routine at trap will save the AC, add one to BETA, and store the augmented value back in BETA. Upon reloading the AC and re-entering the NONTRP routine, the old contents of BETA are stored over the newly augmented value. This could be prevented by disabling the I-O traps before NONTRP and re-enabling them after NONTRP +2.

4. If the 1-0 program is checking for noise records in the end of record gap, the redundancy trap should not to be used to detect noise. Redundancy trapping could occur while reading the first or second word from tape, immediately disconnecting the channel from the tape. A SCHX instruction to investigate the length of this redundant record would show that the

record is only one or two words long, classing it as a noise record. This is an error and may be prevented by always testing for redundancy during the end of operation or end-of-file trap routine with a normal TRCX instruction.

- 5. Care must be taken when writing subroutines which may be entered by both trap and non-trap routines. Entry at trap time to a routine which has been interrupted by the trap can give destructive results.
- 6. Trap time subroutines which issue 1-0 selects should insure that the selected channel is dormant before giving the select. This may be difficult without destroying or ignoring existing trap signals on the selected channel.

For more information on trapping, see "Interrupt."

External Signal

A standard feature of the computer system is its ability to accept a signal from an external source. This signal is stored and will cause the computer to execute a trapping operation as soon as possible. Normally, upon receipt of an external signal, the instruction being executed is completed and the location of the next instruction is stored in the address portion of core location 0003. The computer then takes its next instruction from location 0004. If, however, the current instruction is a floating point trap instruction which causes overflow or underflow, the floating point trap will be executed before the external signal trap is allowed to occur. The external signal trap is completely independent of data channel traps. Significant implications of this are:

- 1. If the computer is halted, the trap will not occur until the start key is depressed and the halt operation is completed.
- 2. It is not possible to disable or inhibit an external signal trap.
- 3. The external signal trap is unconditional in that it may occur between an input-output select instruction and the following instruction, a restore channel traps or enable instruction and the following instruction, or an execute instruction and the instruction to be executed. If a trap occurs at one of these times and the external signal trap subroutine is then interrupted by a data channel trap, timing limitations may be exceeded and/or the program may return to the incorrect re-entry location in the main program.

IBM 7909 Data Channel Registers

Registers in the 7909 Data Channel (Figure 16) are:

Character Registers: This seven-position (six data bits and a parity bit) register serves as a buffer for data characters passing between the control unit and the assembly register.

Read and Write Translators: These translators are optional and are used with the BCD translation optional feature. Their function is to translate characters going to and from the control unit when operation is in the BCD mode. The translators are not active during transfer of control data or sense data.

Character Switches: These switches are used to transfer characters into and out of the character register.

Storage Bus Switches: These 36-position switches provide the data path to and from the 7606 Multiplexor for data and command entry into the 7909.

Data Register: This 36-position register is a buffer register for data flow between core storage and the assembly register. During a write or control operation, the data register is loaded with the next data word to be sent to the control unit. On a read or sense operation, the input data are kept in the data register until the data can be placed in core storage.

Assembly Register: This 36-position register assembles and disassembles data passing between the 7909 and the control unit.

Channel Address Switches: This 15-position switch provides the 7606 with address information. The next word needed by the 7909 is obtained by directing the address counter to the channel address switch if data are to be transmitted or by directing the command counter to the channel address switch when a new command is required.

Operation and Control Registers: During a command word cycle, the storage bus switches are directed to the operation register, word counter, and address counter. Positions S, 1, 2, 3, and 19 enter the operation register. These five bits are decoded and provide the 7909 with its next command. Positions 21-35 enter the address counter. During data operations, the address counter contains the location of the next data word. During transfer type commands (TCM, TDC), the address counter contains the location of the next channel command. Positions 3-17 enter the word counter, which is used to control the number of words passed between the 7909 and core storage.

Command Counter: The 15-position command counter contains the location of the next 7909 command. The first operation performed during all command execution-except wrr and rwr-is to step the command counter to the next sequential command location. The command counter is reset and reloaded by execution of an RSC, TCH, LIPT, or successful TCM or TDC command.

Character Ring: The character ring completes a cycle for each character transmitted. Its main use is to synchronize character-bit transmission.

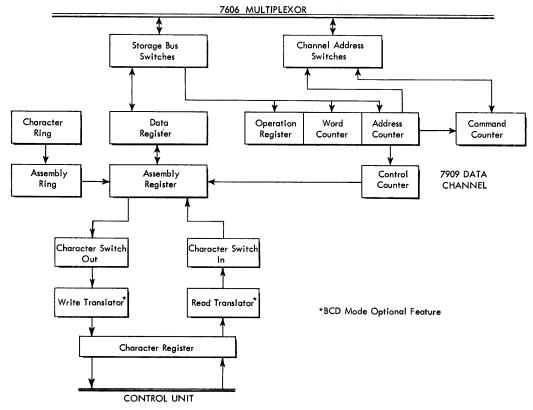

Figure 16. IBM 7909 Data Channel Data Flow

Assembly Ring: The assembly ring is a character counter and gates data into or out of the assembly register as required. During data operations, data are sent to or received from the adapter, one 6-bit character at a time, through the character switches.

Control Counter. This six-position counter is provided for programming convenience. The counter contents may be changed or tested in a variety of ways as described under "7909 Data Channel Commands."

7094 System Configuration

Each IBM 7094 Data Processing System includes:

7109 Arithmetic Sequence	7608 Power Con-
Unit	verter
7110 Instruction Processing	7617 Data Channel
Unit	Console
7151 Console Control Unit	7618 Power Control
7302 Core Storage	711 Card Reader
7606 Multiplexor	716 Printer
7607 Data Channel	721 Card Punch

The 7607 Data Channel is available in four models:

- Model 1 Controls up to ten 729 п and 729 п Magnetic Tape Units and one each івм 711 Card Reader, івм 721 Card Punch, and івм 716 Printer.
- Model 2 Controls up to ten 729 II and 729 IV Magnetic Tape Units.
- Model 3 Controls up to ten IBM 729 II, IV, V, or VI Magnetic Tape Units and one each IBM 711 Card Reader, IBM 721 Card Punch and IBM 716 Printer.
- Model 4 Controls up to ten 729 II, IV, V, or VI Magnetic Tape Units.
- Model 5 Controls one each IBM 711 Card Reader, IBM 716 Printer, and IBM 721 Card Punch.

Eight 7607 Data Channels, with an IBM 7617 Data Channel Console for each data channel may be attached to the 7606 Multiplexor. IBM 729 II and IV Magnetic Tape Units may be mixed on a 7607 Model 1 or Model 2 Data Channel, and 729 II, IV, V, or VI Magnetic Tape Units may be mixed on a 7607 Model 3 or Model 4 Data Channel.

IBM 1301 Disk Storage, IBM 7320 Drum Storage, IBM 7340-1 Hypertape Drives, and IBM Tele-Processing® equipment may be attached to the 7094 system through the IBM 7909 Data Channel. Four 7909 Data Channels may be attached to a 7094 system as long as the total number of data channels (7607 and 7909) does not exceed eight.

With disk or drum storage, an IBM 7631 File Control unit is used between the 1301/7320 and the 7909 Data Channel. Three models of the 7631 are available with the 7094 system:

Model 2: For use with single 7094 operation.

- Model 3: For shared disk operation between a 7094 and a 1410 or 7010 system.
- Model 4: For shared disk operation between a 7094 and another 7000 series (except 7072 or 7010) system.

Five 1301 Disk Storage units or five 7320 Drum Storage units or combinations of 1301/7320 up to five may be attached to the 7094 system through either one or two 7631 File Control units.

When IBM 7340-1 Hypertape Drives are attached to the 7094 system, an IBM 7640 Hypertape Control is used between the 7909 Data Channel and 7340-1 Hypertape Drives. One 7640 Hypertape Control may be attached to a 7094 system. The 7640 has two data paths, and each path must be attached to a 7909 Data Channel. Twenty 7340-1 Hypertape Drives may be attached to a 7640 Hypertape Control.

An optional Data Channel Switch feature may be attached to the 7909 Data Channel, giving the channel two data paths instead of one. Only one input-output device, however, may be in use on a 7909 at one time. Attachment of the 7640 Hypertape Control requires two 7909 Data Channels; however, a 7631 File Control and one-half of the 7640 (one data path) may be attached to the same 7909 if the Data Channel Switch feature is used.

The IBM 1414-6 Input-Output Synchronizer is used when attachment of Tele-Processing equipment is desired. The 1414-6 is attached to the 7909 Data Channel and maximum limitations depend on other equipment (7631 and 7640). The IBM 1009 Data Transmission Unit, IBM 1011 Paper Tape Reader, IBM 1014 Remote Inquiry Unit, and telegraph input-output units may be attached to the 1414-6. The maximum number of input-output devices is governed by the number of buffers each unit requires and is outlined in the IBM 1414-6 Input-Output Synchronizer with 7090 Data Processing System Bulletin, Form G22-6625.

An IBM 7094 Data Processing System is shown in Figure 17. Attachments and possible data paths are shown without regard to the permitted maximums.

Data Flow

With a program stored in core storage, the computer can operate and process data to produce desired results. The computer is directed to perform each of its operations by:

An *instruction*, which is interpreted or decoded by the central processing unit.

A command, which is decoded and executed by a data channel.

An order, which is decoded and executed by a control unit.

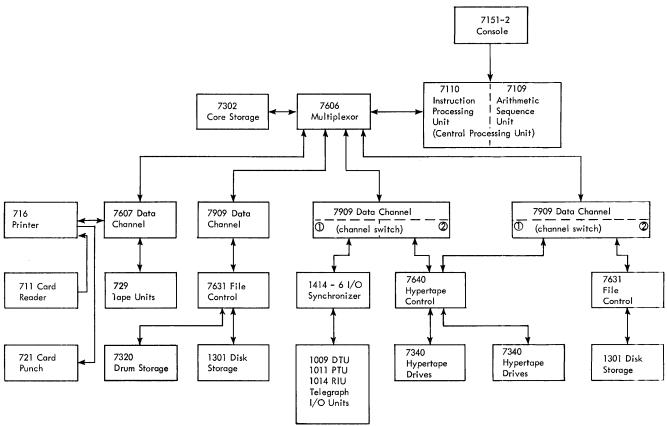

Figure 17. IBM 7094 Data Processing System Configuration

Computer Cycles

The basic computer cycle for the 7094 system is two microseconds. Four different types of cycles are used: instruction (I), execute (E), logic (L), and buffer (B). The cyclic sequence of the computer is fixed, always beginning with an I cycle and progressing to E, L, or B cycles, depending on the instruction.

Although the sequence may be fixed, the number of cycles required, exclusive of the I cycle, is not. The number of cycles required for each activity is determined by the number of steps to be performed before an answer is complete and may vary from as many as 19 cycles to as few as one.

Instruction Cycle

All instructions start with an instruction (I) cycle and some are completed with the I cycle.

If the instruction is addressed to an even-numbered core storage location, the 7094 system always reads two instructions out of core storage: the even-numbered instruction and the immediately higher odd-numbered instruction. If an odd-numbered core storage location is addressed, only the odd-numbered location is read out of core storage.

The I cycle has three purposes:

- 1. To locate and obtain instructions from core storage.
- 2. To establish the execution control circuits for the instruction and, in the case of a single cycle instruction, to execute the instruction.
- 3. To locate the data word, if any, in core storage as specified by the address field of the instruction.

Instruction Cycle Sequence

In the following description of an instruction cycle sequence, it is assumed that the instruction has at least one I cycle and one E, L, or B cycle. The units involved in an I cycle, and appropriate data flow lines, are shown in Figure 18.

The I cycle begins when the instruction counter furnishes the location of the instruction to be decoded to the core storage "word locator," the multiplexor address switch. Controls for reading the instruction are automatically set up and the instruction word taken from core storage goes to the multiplexor storage bus. From the multiplexor storage bus, the instruction is read into the storage register, where it is separated into the operation portion and the address portion of the instruction word. The operation por-

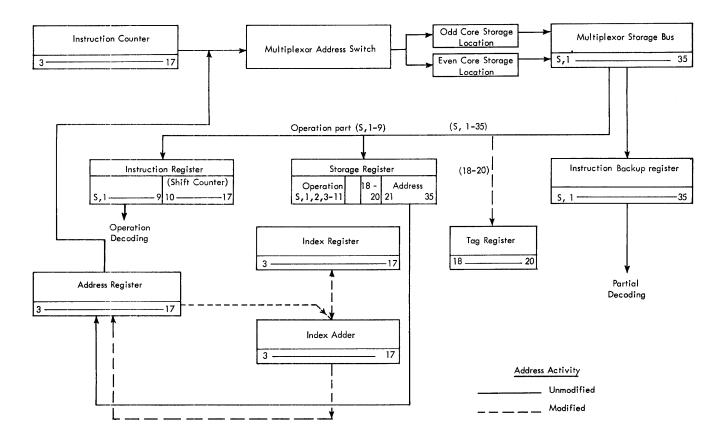

Figure 18. Simplified Instruction Cycle Flow

tion of the storage register goes into the instruction register, where the operation code is decoded and the execute control circuitry is set up to perform the operation specified by the instruction. The address portion of the instruction word, now located in the storage register, may be used directly or it may require modification. If the address is to be used directly, it goes to the address register and then to the multiplexor address switch to locate the appropriate data word in storage. If the address is to be modified, it is routed from the storage register to the index adders via the address register for index adder/index register modification activity. The modified address is then brought to the address register and on to the multiplexor address switch to locate the data word in core storage.

During the same instruction cycle and at the same time, a second instruction, located at the immediately next higher odd-numbered core storage address location, is brought to the instruction backup register (IBR). While in the IBR, the odd-numbered instruction is partially decoded to determine if it meets certain criteria for instruction overlap operation. See "Instruction Overlap." If it is determined that overlap is possible, the computer acts on the two instructions simultaneously. If the instruction in the IBR cannot

be overlapped, it is ignored in the current I cycle and is brought into the storage register on the next I cycle.

Execution Cycle

The execution (E) cycle is used when a reference to core storage is needed. All instructions requiring an operand must have an E cycle following the I cycle.

Indirect addressing of an instruction always requires an extra E cycle. In other words, an instruction that normally goes from I to E to be executed will go to I, E, and again to E if it is indirectly addressed.

Logic Cycle

The L cycle is an execute cycle that does not require a reference to core storage. Many instructions use both E and L cycles when information is required from storage and the instruction cannot be completed during an E cycle. Other instructions require no reference to storage and, therefore, use only I and L cycles for their completion.

Generally, instructions whose operating coding is 0200 through 0667 have an E cycle immediately following the I cycle. The remaining instructions usually go from I to L.

Buffer Cycle

A buffer (B) cycle is used by the data channels to get information from or to put information into core storage. This information can be either data or data channel commands. All demands for B cycles come from the channels themselves. Because of the nature of input-output devices, the demand for a B cycle must take precedence over an instruction being performed in the CPU. Otherwise, the information coming from or going to the data channel might not be transmitted in time.

When an instruction having multiple L cycles is being executed and a B cycle is demanded, the data channel shares cycles (B and L) with the CPU. This means that during any given cycle, both L and B cycles may be performed together. If a convert instruction, using many E cycles, is being executed, a B cycle demand can interrupt the CPU for its storage reference.

Central Processing Information Flow

Information flow is shown in Figure 19.

Central Processing Unit Registers and Counters

Instruction Counter (IC). The instruction counter is 15 positions long to accommodate the largest core storage address.

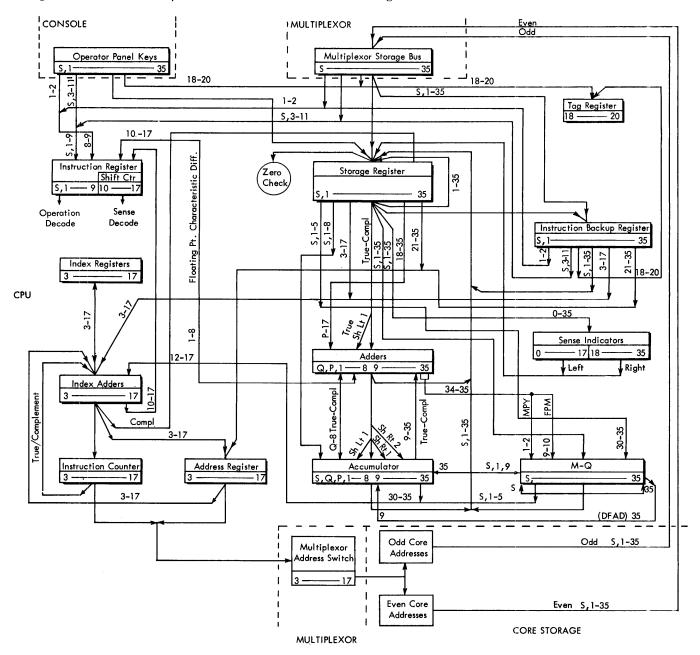

Figure 19. Central Processing Unit Information Flow

The IC is used to tell the computer the location of the next instruction to be performed. It may be reset to zero at the start of a program or may be set to a predetermined address. Once the program is started, the IC counts sequentially unless a transfer instruction is executed. In this case, the IC is set to the address specified by the transfer instruction and is again stepped sequentially starting with this new address. The highest location in core storage and location zero are treated as consecutive addresses.

The IC is normally advanced at the end of each I cycle. However, some instructions cause the computer to skip one or two instructions and, therefore, the IC may be advanced as many as three times while the instruction is being completed. If a halt occurs during the execution of a divide or halt instruction or a halt and proceed instruction, the IC has the address of the instruction being executed *plus one*. Upon execution of a halt and transfer instruction, the IC contains the address of the halt instruction.

If the auto-manual switch is depressed to suspend the execution of a CPU program, the ic contains the address of the instruction to be executed.

Instruction Backup Register (IBR). The instruction backup register is a 36-position register and is used during instruction overlap operations. Its positions are labeled S, 1-35. When the instruction reference is to an even location, the IBR is loaded with the contents of the next higher odd address after the contents of the even address have been placed in the storage register. The IBR may also be loaded from the storage register during double-precision operations and during the ERA (exclusive or to accumulator) instruction.

Address Register (AR). The address register receives its information from the storage register or instruction backup register at the beginning of a storage reference cycle (I or E cycle) and can be modified by index-register/index-adder activity. The contents of the AR are sent to the multiplexor address switch to set up the proper core storage location to be used.

Instruction Register (IR). Instructions and data are both in the form of 36-bit words, and the computer finds the difference between the two in the following manner:

- 1. Any word brought into the computer during an I cycle is treated as an instruction.
- 2. A word brought in during E time is treated as data.

All information coming into the CPU from core storage is placed in the storage register; information will also be placed in the IBR if it comes from an odd core

storage location during overlap operation. Since it is desirable to hold an instruction until it is completely executed, instructions are also held in the instruction register to make room in the storage register for data that may be required by the instruction.

NOTE. A transfer instruction at an odd address location may be taken from core storage and placed in the instruction backup register and executed in instruction overlap without being placed in the storage register.

The IR is divided into two parts. Positions S, 1-9 always contain the operation part of the instruction, while positions 10-17 form a counter known as the "shift counter." In shifting, multiplication, division, and floating-point instructions, the number of shifts to be made is placed in this shift counter and counted down in the execution of the shift operations. The shift counter is also used during floating-point operations to line up digits. During a MPY, MPR, DVH, or DVP operation, a constant of 43₈ is placed in the shift counter. When the shift counter is not being used for shifting, positions 10 through 17 may contain:

A sense instruction address.

Operation codes for those instructions which require an address part.

The class and unit codes for input-output instructions.

Note: Data channel addresses are decoded from the storage register itself.

The storage register (sr) has a capacity of 36 bits and serves as a buffer between core storage and the CPU. It is used for both arithmetic and control functions. For this reason the contents of the sr are always destroyed before the execution of a new instruction. Therefore, the sr is not a normal object of concern to the programmer except when manually stepping through a program in order to locate program errors.

The accumulator register (AC) has a capacity of 37 bits and a sign position. In addition to the normal 36 positions, the AC has two extra positions, Q and P, which precede position 1. These two positions are provided for accumulator overflow. When the sum of 35-bit numbers is a 36-bit result, a carry occurs out of the high-order position (position 1) and is placed in the P position. Similarly, a carry from P is placed in Q. Carries from Q are lost. Whenever a carry from position 1 to position P occurs, as a result of a fixed-point arithmetic or shifting instruction, the overflow indicator is turned on. The status of the overflow indicator may be tested by two of the computer's conditional control instructions.

Multiplier-Quotient Register (MQ). The MQ register has 36 positions. During a multiply instruction, this register contains the multiplier; during a divide in-

struction, it receives the quotient. It can store and shift a full 36-bit word. In addition to shifting right or left, it can also "ring shift" or "rotate." That is, bits shifted out of the sign position enter position 35. With regard to multiplication and some shift operations, the MQ may be considered as a right-hand extension of the Ac register.

Sense Indicator Register (SI). The sense indicator register is 36 positions long and is used to store words or parts of words for use in a calculation, or for matching or comparing results. It is controlled by the program and is used as a storage register in doubleprecision arithmetic operations. It is normally used as a set of switches which are set and tested by the program to determine the progress of a program.

Index Registers (XR). The seven 15-position index registers in the 7094 system are used for address modification. They are called into use by the tag positions of an instruction (positions 18-20) and modify an address by adding the 2's complement of their contents to the address. In effect, the address is reduced by the contents of the index register.

In Multiple Tag mode, index registers 1, 2, and 4 operate in parallel; that is, they are subject to multiple tagging. When the system is operating in seven index register mode, index registers are not operated in parallel and are not subject to multiple tagging.

Many instructions operate on the index registers and make them useful programming tools for such functions as counting, word alteration and program loop control.

Tag Register (TR). This register holds the tag field of the instruction being executed. Tag bits enter the register from console entry keys, multiplexor storage bus, or instruction backup register.

Index Adders (XAD.) A separate 15-position index adder is used with the index register operations. All storing, loading, changing, and modifying of index registers is accomplished through the index adders.

Computer Instructions

This section defines all computer instructions and describes their execution, indicators that may be affected, and timing.

Instruction Diagrams

A diagram representing the format of the instruction is given for each instruction. Preceding this diagram is the alphabetic code which identifies the instruction. The official name of the instruction is also given:

CLA — Clear and Add

Sample Format of Instructions

The numerical operation code is given in the octal number system. This can be easily converted to the binary system for reference to the bit pattern interpreted by the computer. The numbers appearing beneath the diagram indicate the bit positions of the computer-word that are concerned with this particular instruction.

The symbol "Y" appearing in the diagram denotes the address part of the instruction. Y may stand for the address of a word in core storage, the length of a shift, or the address of an input-output unit. For some index transmission instructions, Y may also represent a number which is to be loaded either in true or complement form into an index register.

For some instructions, positions 21-35 are used to contain part of the operation code. The appearance of octal numbers instead of Y in the address field will distinguish this type of instruction from others. In all cases, the full operation code is shown by its octal representation.

Those instructions for which indirect addressing may be specified will have the symbol F (flag) appearing in positions 12 and 13 of the instruction diagram (see figure). This symbol represents 1 bits in both positions 12 and 13 of the instruction. The description of those operations which can have indirect addressing will be defined in terms of direct addressing.

Similarly, for instructions that are subject to effective address modification by an index register, the diagram has the symbol T in the tag field of the instruction. This T is also used to specify any index register to be changed, stored, or tested. The description accompanying an instruction defines the manner in which it is executed when its tag is zero.

The shaded area in the instruction diagrams represent fields that are not used in that instruction.

The symbols D, C, and R are used to denote the decrement, count, and right-half word fields of instructions which use these fields. Each of these fields is interpreted only by certain classes of instructions. If such a field is interpreted by an instruction, the bit positions used by the field will be shown in the instruction diagram. If an instruction has a D or R part, neither indirect addressing nor effective address modification is ever possible.

Definitions

- 1. C(Y) denotes the contents of location Y, where Y refers to some location in storage. Similarly, C(AC), C(MQ), C(SR) and C(SI) denote the contents of the accumulator, multiplier-quotient, storage and sense indicator registers, respectively. In addition, subscripts refer to individual bit positions of a register. For example, C(MQ)_{S, 1-17} is read "the contents of positions S, I through 17 of the MQ." When subscripts are not used with this notation, the entire register is implied. For example, C(AC) denotes the contents of positions s,Q,P, 1-35, inclusive.
- 2. With input-output operations, DC denotes data channel, LR denotes DC location counter, AR denotes DC address counter, and WR denotes DC word counter.
- 3. When a register or part of a register is *cleared*, the cleared part is reset to zeros.
- 4. The negative of a number is the number with its sign reversed.
- 5. The magnitude of a number is the number with its sign made positive. (A zero in position S corresponds to a positive sign.)
- 6. When the word "store" is used in the title of an instruction, the transmission of a word or part of a word from some special register (e.g., the AC, MQ, SI or an index register) to some location in core storage is always implied.
- 7. When the word "load" is used in the title of an instruction, the transmission of a word or part of a word from some location in core storage to some special register (e.g., the MQ, SI, or DC registers, but not the AC) is always implied.

- 8. When the word "place" is used in the title of an instruction, the AC is always one of the agents.
- 9. All logical operations interpret the sign position (S) of Y as a numerical binary bit corresponding to position P of the AC or position 0 of the SI. The S position of the AC is either ignored or cleared by logical operations.
 - 10. In the three-letter alphabetic code:
 - a. The letter Q designates the MQ register.
 - b. The letter X in the second or third position designates an index register.
 - c. The first letter of all transfer instructions is a T.

In the following instruction descriptions, an instruction format is shown for each instruction. Under the "Indicator" heading, only those indicators that may alter the course of a program through test instructions or by trapping are noted. Under the "Execution" section, when instructions are similar, only the differences are noted and a statement (e.g., "Same as ADD procedure") will mean that the operations are alike except for the differences noted. Instruction flow charts are used with many instructions to aid in presenting the data flow.

Note again that all addresses and numbers, unless otherwise specified, are given in the octal number system.

Instruction Timing and Overlap

Three kinds of overlap are possible on the 7094 system:

Data Overlap in which the need for an operand from core storage is anticipated.

Store Overlap in which the need to refer to storage for a store operation is anticipated.

Transfer Overlap in which a transfer function is anticipated.

Each instruction reference to core storage results in two words being available (contents of the even and next higher odd address). If the instruction reference is to an even location, both the instruction addressed and the next sequential instruction are brought to the processing unit. In most cases, this next instruction is then available to the processing unit when it is needed without requiring an additional storage cycle for the instruction fetch. This results in a reduction of one cycle in execution time for most instructions located in odd locations in core storage. Timing rules for this instruction overlap are:

Data Overlap: If the instruction in the even location has a cycle time of two or more cycles (excluding 06xx store types codes) and is indexable, and the instruction in the next higher (odd) location requires a data fetch (not a store operation) from core storage, the execution time of this next instruction is reduced by one cycle.

Store Overlap: If the instruction in the even location has an octal code of 06xx (store type instruction), the execution time of the next instruction is reduced by one cycle. If the instruction following an 06xx octal code instruction is a one cycle instruction, it is executed in overlapped operation and requires no cycle time.

Transfer Overlap: If the instruction in the even location has an octal code of 02xx, 03xx, 04xx, or 05xx (except 052x and 053x) and the next instruction is TRA, TTR, TXI, TIX, TNX, TXH, TXL, or TSX, this instruction is executed in overlapped operation and requires no cycle time.

There are some exceptions to these rules because of logical and compatibility reasons. For example, if the address of an 06xx octal code instruction located at address $2n ext{ is } 2n + 1$, no overlap is possible. If a multiple tagged index modification instruction is in an odd location, no overlap occurs. Overlap is not effective for data or transfer overlap if the instruction in the even location is: (1) DVH, FDH, VDH, HPR, LCH, RCH, ENB, XEC, or ERA, (2) is non-indexable, or (3) is a double-precision floating-point instruction.

Research on instruction mixes indicates that out of 100 instructions executed, between 40 and 45 instruction fetches will be eliminated. If the rules are not applied, a rule of thumb is to reduce cycle times for all instructions executed by 0.4 cycles (0.8 micoseconds).

Fixed Point Operation

CLA - Clear and Add

Description. The $C(AC)_{S, 1-35}$ are replaced with the C(Y). Positions P and Q of the AC are set to zero. The C(Y) remain unchanged.

Indicators. None.

Timing: 2 cycles

Execution. The C(Y) are brought to the SR. $C(SR)_{1-35}$ is taken to the adders, the adders to $AC_{(1-35)}$ and the SR(S) to AC(S).

CAL — Clear and Add Logical Word

Description. The c(y) replace the $c(Ac)_{P,1-35}$. The sign of Y appears in position P of the Ac. Positions S and Q of the Ac are set to zero. The c(y) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. The SR (S) goes to adder position P. The rest of the operation is the same as for CLA.

CLS — Clear and Subtract

Description. The negative of C(Y) replaces the $C(AC)_{8,1-35}$. Positions P and Q of the AC are set to zero. The C(Y) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. (1) Invert sign of Y as it is entered into the SR. (2) Same as CLA.

The logic flow diagram for both the CLA and CLS instructions is shown in Figure 20.

ADD — Add

Description. The c(y) are algebraically added to the c(Ac). The resulting sum is placed in the Ac.

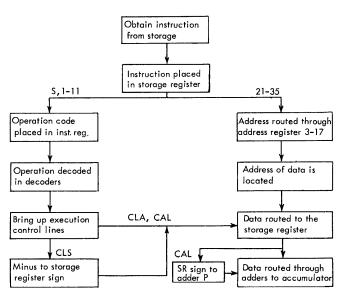

Figure 20. CLA, CAL, and CLS Flow Chart

The c(Y) are unchanged. Numbers of the same magnitude but different signs give a resultant sign the same as the sign of the original AC.

Indicators. AC overflow.

Timing: 2 cycles

Execution. The C(Y) are taken to the SR and then to the adders. With signs alike, the true AC(Q-35) is also taken to the adders, and the sum returned to the AC. With signs unlike, the complement of the AC (Q-35) is taken to the adders; any Q carry is taken to adder 35 and is remembered. The resultant sum in the adders is then taken back to the AC. If the signs were unlike and there was no Q carry, the complement of the AC(Q-35) is again taken to the adders and then back to the AC. With a Q carry, reverse the AC sign (Figure 21).

ADM - Add Magnitude

Description. The magnitude of the c(y) is added to the c(Ac). The resulting sum is placed in the Ac. The c(y) are unchanged. The sign of Y is ignored and Y is treated as a positive number. With a minus Ac sign, a subtractive process will occur.

Indicators. AC overflow.

Timing: 2 cycles

Execution. (1) SR (s) is forced plus. (2) Procedure is the same as for ADD.

SUB - Subtract

Description. The c(y) are algebraically subtracted from the c(Ac). The difference replaces the c(Ac). The c(y) are unchanged.

Indicators. AC overflow.

Timing: 2 cycles

Execution. (1) Sign of sR is reversed. (2) Same as ADD procedure.

SBM — Subtract Magnitude

Description. The magnitude of the c(y) is subtracted from the c(AC). The difference is placed in

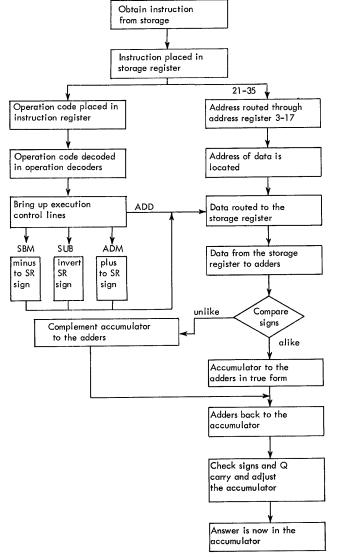

Figure 21. ADD, ADM, SUB, and SBM Flow Chart

the c(AC). The sign of Y is ignored and the c(Y) are treated as a negative number. The c(Y) are unchanged. If the sign of the AC is minus, an ADD will occur.

Indicators. AC overflow.

Timing: 2 cycles

Execution. (1) SR (s) is forced minus. (2) Same as add procedure.

The logic flow diagram for the ADD, SUB, ADM, and SBM instructions is shown in Figure 21.

ACL — Add and Carry Logical Word

Description. The C(Y) are added to the $C(AC)_{P,1-35}$. The resultant sum replaces the $C(AC)_{P,1-35}$. The sign of Y is added to position P of the AC. A carry from AC(P) is added to AC(35). Positions S and Q of the AC are not affected.

Indicators. None.

Timing: 2 cycles

Execution. The C(Y) are taken to the sr. The SR(s, 1-35) are then taken to the adders (P, 1-35). An adder P carry goes to adder 35. Adders (P, 1-35) are then returned to AC(P, 1-35).

MPY - Multiply

Description. The c(Y) are multiplied by the c(MQ). The 35 most significant bits (in terms of physical position) of the 70-bit product (formed by combining the AC and MQ) replace C (AC) 1-35 and the 35 least significant bits of the product replace the C (MQ) 1-35. AC_{P,Q} are cleared. The signs of the AC and MQ are both set to the algebraic sign of the product. To determine the placement of the binary point in the product, the number of bits to the right of the binary point of the first factor are added to the number of bits to the right of the binary point in the product.

Indicators. None

Timing: 2-5 cycles.

Execution. (1) The C(Y) are tested, and if the magnitude of the C(Y) is zero, the C(AC) and C(MQ)

are cleared. Step 2 is skipped and step 3 occurs. (2) If the magnitude of the c(Y) is not zero, the c(AC)_{Q,P,1-35} are cleared and multiplication proceeds:

IF MQ _{34–35} HAVE THIS BIT	
CONFIGURATION	MULTIPLY ACTIVITY
0 0	Shift c (AC) $_{Q_i}$ $_{P_i}$ $_{1-35}$ and c (MQ) $_{1-36}$ two bit positions to the right. No addition is made.
0 1	The $C(Y)_{1-35}$ are added to the AC. The $C(AC)_{Q, P, 1-35}$ and the $C(MQ)_{1-35}$ are shifted two bit positions to the right.
1 0	The $C(Y)_{1-36}$ are shifted one bit position to the left. The left-shifted $C(Y)_{1-36}$ are now added to the Ac. The $C(AC)_{Q, P, 1-36}$ and the $C(MQ)_{1-36}$ are now shifted two bit positions to the right.
11	The $C(Y)_{1-35}$ is subtracted (2's complement add) from the contents of AC. The $C(AC)_{Q, P, 1-35}$ and the $C(MQ)_{1-35}$ are now shifted two bit positions to the right. A 1 bit is automatically added to the multiplier before the next iteration.

(3) If the signs of the MQ and location Y are the same, the signs of the AC and MQ are made positive. If the signs differ, the signs of the AC and MQ are made negative.

The flow chart is shown in Figure 22.

An example of the use of the bit configurations is in the table at the bottom of this page. The number $27_{\rm s}$ is to be multipled by $33_{\rm s}$. Six bit positions will be used in the example rather than the normal 35 bit positions.

MPR — Multiply and Round

Description. This operation is the same as multiply except that the c(Ac) are increased by 1 if MQ(1) contains a one after multiplication is complete.

Indicators. None.

Timing: 2-5 cycles

Execution. (1) Develop the product as in multiply. (2) If MQ(1) contains a 1, add a 1 to AC(35).

RND - Round

Description. If position 1 of the MQ contains a 1, the C(AC) are increased by one. If MQ(1) contains a 0, the C(AC) are unchanged. In either case the C(MQ) are unchanged. Note that positions 24-35 of this instruction represent part of the operation code. Modification by indexing may change the operation code itself.

Indicators. AC overflow.

Timing: 2 cycles

Execution. If MQ (1) contains a 1, the C (AC) $_{Q-35}$ is sent to the adders with a carry to adder 35. The adder (Q-35) is then taken to AC (Q-35). If MQ (1) contains a 0, no rounding occurs.

AC QP	MQ	Y	ITERATION	COMMENTS	MULTIPLY ACTIVITY	BIT CONFIGURATION
000000	010111	011011	1	Initial contents of registers. MQ $_{34,\ 35}$ ready to be tested	-1X	11
100100	010111			C(Y) complemented and sent to AC		
1*1* 1*				Ones added to Q, P, and low-order bit position		
1 1 100101	010111			Add to AC		
111001	010101			Combined AC and MQ shifted two bit positions to the right. This is first partial product		
110110 carry	010101		2	C(Y) shifted left one bit position on way to	2X	10
< ≪ 101111				Add c(Y) into AC		
001011	110101			Combined AC and MQ shifted two bit positions to the right. This is the second partial product		
011011			3	C (Y) to AC	1X	01
100110	110101			Add C(Y) to AC		01
001001	101101			Combined Ac and MQ shifted two bit posi-		
1 1	5 5			tions to the right. Shift counter is now at 0. This is the answer		

Proof: $27_8 = 23_{10}$ and $33_8 = 27_{10}$ $23_{10} \times 27_{10} = 621_{10}$ $621_{10} = 1155_8$ Ans.

^{*} q and p are used in a -1X multiply activity to signal the computer that a complement addition has been performed. The one is added to the low-order position to perform a true subtraction (addition of the 2's complement).

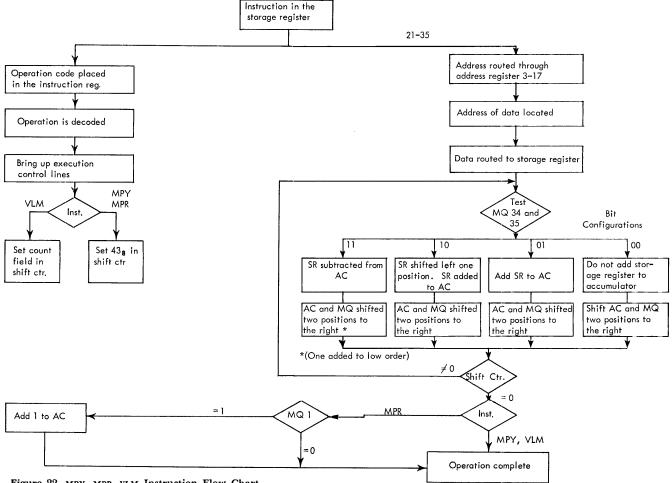

Figure 22. MPY, MPR, VLM Instruction Flow Chart

VLM — Variable Length Multiply

Description. This instruction multiplies the C(Y) by the C low-order bits of the c (MQ), to produce a 35 + Cbit product. The 35 most significant bits of the product replace the C(AC)₁₋₃₅ and the C least significant bits replace the C (MQ) 1 through C. Positions Q and P of the AC are cleared. The remaining 35—C positions of the MQ will contain the original 35-C highorder positions of the MQ. The sign of the AC and MQ is the algebraic sign of the product. An example is shown in Figure 23.

If C is zero, the instruction is interpreted as a nooperation and the computer proceeds directly to the next instruction in sequence, leaving the AC unchanged.

If C is not zero but the C(Y) are zero, the C(AC) and C (MQ) are cleared. If the signs of the MQ and location Y are the same, the signs of the AC and MQ are made positive. If the original signs of the SR and MQ differ,

the signs of the AC and MQ are made negative. Note: A count field which places a 1 bit in both positions 12 and 13 (60 or larger) will cause indirect addressing. In general, counts larger than 35 are meaningless.

Indicators. None.

Timing: 2-5 cycles

Execution. The instruction is the same as multiply except that the contents of the count field, instead of 43, are placed in the shift counter.

Figure 22 shows the flow chart for MPY, MPR, and VLM instructions.

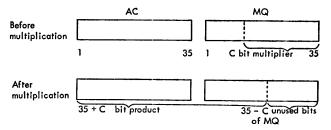

Figure 23. Variable Length Multiply

DVH - Divide or Halt

Description. The $c(AC)_{Q,P,1-35}$ and the $c(MQ)_{1-35}$ are treated as a 70-bit dividend plus sign, and the c(Y) as a 35-bit divisor. If the magnitude of c(Y) is greater than the magnitude of c(AC), division takes place. A 35-bit quotient replaces the $c(MQ)_{1-35}$ and the remainder replaces the $c(AC)_{1-35}$. The MQ sign is the algebraic sign of the quotient and the AC sign is the sign of the dividend.

If the magnitude of the c(x) is less than or equal to the magnitude of the c(AC), division does not occur and the computer stops with the divide-check indicator on. For example, if Q or P of the AC contains a 1, the magnitude of the c(x) is less than the c(AC). If division does not occur, the dividend remains unchanged in the AC and MQ.

Indicators. Divide check

Timing: 3-8 cycles

Execution. (1) The c (Ac and MQ) $_{1-35}$ are shifted left one position, creating a zero in position 35 of the MQ. (2) If the magnitude of the c (Y) is less than or equal to the magnitude of c (AC), the magnitude of c (Y) is subtracted from the magnitude of c (AC) and a one replaces the zero in MQ₃₅. Step 1 is then repeated (Figure 24). (3) If the magnitude of the c (Y) is greater than the magnitude of the c(AC), the computer returns to step 1.

The following example is a division problem. Assume we have a four-bit machine. The problem is 66 divided by 5, and the binary numbers represent the result of the described step.

DIVIDEND DIVISOR

AC	MQ	Y	COMMENTS
0100	0010	0101	Initial contents. $c(AC)$ less than $c(Y)$; division will take place.
1000	0100		C (AC and MQ) shifted left one place; C (AC) greater than C (Y).
0011	0101		c (Y) subtracted from c (AC) and a 1 replaces MQ 35.
0110	1010		c (Ac and MQ) shifted left one place; c (AC) greater than c (Y).
0001	1011		C(Y) subtracted from C(AC) and a 1 replaces MQ 35.
0011	0110		C (AC and MQ) shifted left one place; C (AC) less than C (Y).
0110	1100		C (AC and MQ) shifted left one place; C (AC) greater than C (Y).
0001	1101		C(Y) subtracted from C(AC) and a 1 replaces MQ 35.
RMDR	QUOT		The quotient is now complete in the MQ with the remainder in the AC.

DVP — Divide or Proceed

Description. If the magnitude of the C(Y) is greater than the magnitude of the C(AC), division occurs as with the DVH instruction. If the magnitude of the C(Y) is less than or equal to the magnitude of the C(AC), the divide-check indicator is turned on and the computer proceeds to the next instruction.

Indicators. Divide check

Timing: 3-8 cycles

Execution. Exactly the same as DVH except that instead of halting, when a divide-check occurs, the computer executes the next sequential instruction (Figure 24).

VDH — Variable Length Divide or Halt

Description. This instruction is the same as a DVH except that a C-bit quotient plus sign replaces the C low-order positions of the MQ. The remainder replaces the C (AC) 1-35 and the 35—C high-order positions of the MQ. Instead of 43 being placed in the shift counter initially, C is placed there. If C is zero the instruction is interpreted as a no-operation and the computer proceeds directly to the next instruction in sequence.

Indicators. Divide check.

Timing: 2-8 cycles

Execution. The same operation as DVH except as noted above.

Note: Indirect addressing may occur if the count field places 1-bits in positions 12 and 13 of the instruction (Figure 24).

VDP — Variable Length Divide or Proceed

Description. This instruction is the same as DVP except that a C bit quotient with a sign replaces the C low-order positions of the MQ. The remainder replaces the C (AC) 1-35 and the 35—C high-order positions of the MQ. C rather than 43 is placed in the shift counter initially. If C is zero the instruction is interpreted as a no-operation and the computer proceeds directly to the next instruction in sequence.

Indicators. Divide check.

Timing: 2-8 cycles

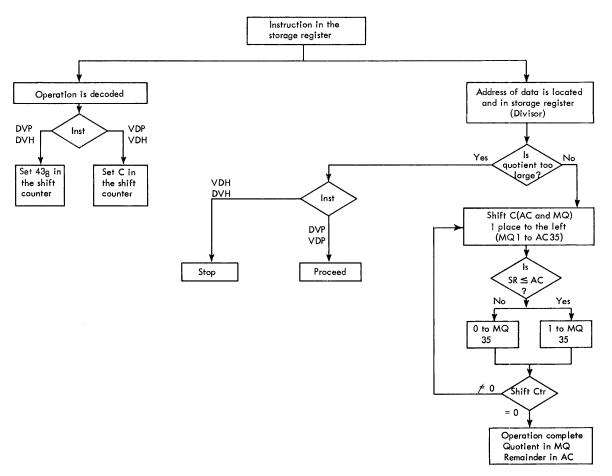

Figure 24. DVH, DVP, VDH, and VDP Flow Chart

Execution. The same procedure as DVP except as noted above.

Note: Indirect addressing may occur if the count field places 1 bits in positions 12 and 13 of the instruction.

Figure 24 shows the logic flow chart for DVH, DVP, VDH, and VDP instructions.

Floating Point Operations

The following operations are divided into two groups to describe the processing of floating-point numbers in either normalized or unnormalized form. The possibility of floating-point overflow or underflow during the execution of a floating-point instruction is indicated by an asterisk (*). All conditions of underflow and overflow are discussed following the last floatingpoint instruction.

Floating Point Arithmetic

The algebraic addition of two floating-point numbers in the computer is analogous to the ordinary algebraic addition of two signed numbers with decimal points. An example is the algebraic addition of the two numbers 100 and -0.1009:

$$\begin{array}{r}
100.0000 \\
-0.1009 \\
\hline
99.8991
\end{array}$$

Note that the second number must be shifted to the right to line up the decimal points, and that the first number must be supplied with additional zeros. The same addition performed with numbers expressed in floating-point decimal form, would be:

$$-.1000 \times 10^{3}$$
 $-.1009 \times 10^{0}$

Again, before the addition, the lower number is shifted to the right with a compensating change in

the exponent and corresponding zeros are added to the number on the upper line:

$$\begin{array}{l}
.1000000 \times 10^{3} \\
--.0001009 \times 10^{3} \\
\hline
.0998991 \times 10^{3} = .998991 \times 10^{2}
\end{array}$$

Note also that the digits of the answer must be moved to the left to be in normalized form and that the final fraction contains more digits than either of the two numbers involved in the addition.

In the computer the two numbers are expressed as binary fractions, each having an 8-bit binary characteristic to represent the exponent of 2. The "lining up" is done by shifting from the Ac into the MQ. The result of an addition or multiplication is normalized by shifting the fractions in the Ac and MQ left while making compensating changes in the characteristic of the sum or product.

FAD - Floating Add

Description. The floating-point numbers located in Y and the AC are added together. The most significant portion of the result appears as a normal floating-point number in the AC. The least significant portion of the result appears in the MQ as a floating-point number with a characteristic 33 (octal) less than the AC characteristic. The signs of the AC and MQ are set to the sign of the larger factor. The sum in the AC and MQ is always normalized whether the original factors were normal or not. If C (AC) 1-35 contain zeros, the FAD may be used to normalize an unnormal floating-point number.

Indicators. Floating-point underflow, overflow, and floating-point trap.

Timing: 2-12 cycles

Execution

- 1. The MQ register is cleared to zeros.
- 2. The c(Y) are placed in the sr.
- 3. If the characteristic in the sR is less than the characteristic in the AC, the c(sR) and $c(AC)_{s,1-35}$ are interchanged, as the number with the smaller characteristic must appear in the AC before addition can take place.
 - 4. The MQ is given the same sign as the AC.
- 5. If the difference in the characteristics is greater than 77_8 the c (AC) are cleared. If the difference in the characteristics is a number N_8 less than or equal to 77_8 , the c (AC) $_{9\text{-}35}$ are shifted right N_{10} places (where N_{10} is the decimal equivalent of N_8). Bits shifted out of position 35 of the AC enter position 9

of the MQ. Bits shifted out of position 35 of the MQ are lost.

- 6. The characteristic in the sR replaces the C(AC)₁₋₈.
- 7. The $C(SR)_{9-35}$ are added to the $C(AC)_{9-35}$ and this sum replaces the $C(AC)_{9-35}$. If the signs of the AC and SR are unlike, the $C(SR)_{9-35}$ are added to the l's complement of the $C(AC)_{9-35}$. Since the $C(AC)_{9-35}$ represent a pure fraction, the magnitude of their l's complement is equal to $(1-2^{-27}) C(AC)_{9-35}$.
- 8. Regardless of the sign or relative magnitudes of the SR and AC, the result appears in double-precision form with signs alike in both the AC and MQ. If the signs of the AC and SR are the same and the magnitude of the sums of the fractions is greater than or equal to one, there is a carry from position 9 into position 8 of the AC. Thus, the characteristic of the AC is increased by one.* In this event, the fractions of the AC and MQ are shifted right one position and a 1 is inserted into position 9 of the AC. If the signs of the AC and SR are different, there are two cases, both depending on the difference between the SR and AC fractions.
 - CASE 1. If the magnitude of the SR fraction is greater than the fraction in the AC, the AC and MQ signs are both changed to the sign of the SR. If the fraction of the MQ is zero, the difference between the fractions of the SR and AC is placed in the AC. If the fraction of the MQ is not zero, the difference between the fractions of the SR and AC, minus one, is placed in the AC; the 2's complement of the MQ fraction replaces the fraction in the MQ.

CASE 2. If the magnitude of the SR fraction is less than the fraction in the AC, the difference of the two fractions replaces the fraction of the AC. The sign of the AC and the entire MQ remain unchanged.

9a. If the resulting fractions in both the AC and MQ are zero, the AC is cleared, yielding a normal zero. If the fractions are in normalized form before the FAD is given, this result can only occur if the signs are different and the $C(Y)_{1-35}$ are equal to the $C(AC)_{1-35}$. The signs of the AC and MQ will be equal to the sign of the number originally in the AC. If the resulting fraction in the AC is zero and the two numbers were not in normalized form before addition, the signs of the AC and MQ are equal to the sign of the original number having the smaller characteristic.

9b. If the resulting fractions in the AC and MQ are not zero, the fractions of the AC and MQ are shifted left until a 1 appears in position 9 of the AC. Bits enter position 35 of the AC from position 9 of the MQ. The characteristic in the AC is reduced by one for each

position shifted.* No shifting is necessary if the fraction of the AC is in normal form at the beginning of this step.

10. The MQ is given a characteristic which is 27 less than the characteristic in the AC,* unless the AC contains a normal zero, in which case zeros are left in positions 1-8 of the MQ.

If the P and/or Q positions of the AC are not zero before the execution of the FAD, the result will usually be incorrect. Non-zero bits in P and/or Q which are initially interpreted as part of the AC characteristic make it larger than the characteristic in the SR so that the interchange in step 3 will always take place. During the interchange a 1 will be placed in position S of the sR if there is a 1 in either S or P positions of the AC, so that the sign of the number may be changed. Any bit in Q is lost during the interchange and both P and Q are cleared when the c (SR) replace the c (AC). The difference between the two characteristics is computed after the interchange occurs, so that in step 5, N will not be equal to the difference between the original characteristics. In step 6 the characteristic in the sR, with its Q and P bits missing, replaces the characteristic in the Ac. Consider as a sample problem the addition of:

$$2^2 \times .1001 = (SR) + 10000010.1001$$

 $2^5 \times .1001 = (AC) + 10000101.1001$

First, the exponents must be equalized and then the addition may proceed. The characteristics are checked and found unequal, with the largest in the Ac. The numbers in the Ac and SR are then exchanged, giving:

The MQ content is zeros at this time. The C(AC) 9-88 are then shifted right the number of places needed to equalize the exponents. (Remember that the binary point is located between positions 8 and 9 of all registers.) The registers then appear as:

SR	+10000101.1001
AC	+10000101.0001
MQ	+00000000.0010

The fractions (positions 9-35) may now be added.

SR	+10000101.1001
AC	+10000101.1010
MO	+00000000.0010

AC position 9 is checked for a 1 and no normalizing occurs. The MQ characteristic is now set. It is equal to the AC characteristic minus the number of places in the AC fraction (27 in the computer, 4 in this example):

SR	+10000101.1001
AC	+10000101.1010
MQ	+10000001.0010

Decoding the results into the original format, we find:

$2^{5} \times .1001$	$MQ = 2^1 \times .0010$	$0 = 2^5 \times .00000010$
$2^{5} \times .0001001$	AC =	$2^5 imes .1010$
$2^5 \times .1010001$	resultant sum	$=2^{5} \times .10100010$

FAM -- Floating Add Magnitude

Description. This instruction algebraically adds the positive magnitude of the floating-point numbers contained in Y to the signed floating-point number in the Ac. The sum is normalized.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-12 cycles

Execution. The same procedure as FAD except that the magnitude of the number in the SR is used (SR sign is forced plus).

UFA — Unnormalized Floating Add

Description. This instruction algebraically adds two floating-point numbers contained in the AC and Y. The sum is not normalized.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-8 cycles

Execution: The same procedure as FAD except that normalizing does not occur (step 9), and the test for normal zero in the AC (step 10) is not performed.

FSB — Floating Subtract

Description. This instruction algebraically subtracts the floating-point number located in Y from the floating-point number in the AC, and normalizes the result.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-12 cycles

Execution. The same procedure as FAD except that the negative of the C(Y) are placed in the SR (SR sign is reversed).

UAM - Unnormalized Add Magnitude

Description. This instruction algebraically adds the magnitude of the floating-point number contained in Y to the signed floating-point number in the Ac. The sum is not normalized.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-8 cycles

Execution: The same procedure as FAD except that the sign of the number in the SR is made positive, the result is not normalized, and the test for normal zero in the AC (step 10) is not performed.

FSM — Floating Subtract Magnitude

Description. This instruction algebraically subtracts the magnitude of a floating-point number stored at Y from the signed floating-point number in the Ac. The result is normalized.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-12 cycles

Execution. The same procedure as FAD except that the negative magnitude of the contents of Y are used (SR sign is forced minus).

UFS — Unnormalized Floating Subtract

Description. This instruction algebraically subtracts the floating-point number located in Y from the floating-point number in the AC. The result is not normalized.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-8 cycles

Execution: The same procedure as FAD except that the negative of the contents of Y are placed in the SR, normalizing does not occur, and the test for normal zero in the AC (step 10) is not performed.

USM — Unnormalized Floating Subtract Magnitude

Description. This instruction algebraically subtracts the magnitude of a floating-point number stored at Y from the signed floating-point number in the AC. The result is not normalized.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-8 cycles

Execution: The same procedure as FAD except that the negative magnitude of the contents of Y are used, the result is not normalized, and the test for normal zero in the AC (step 10) is not performed.

FRN — Floating Round

Description. Floating-point add, subtract, and multiply produce a double-word result. The instruction FRN will add 1 to position 35 of the AC if the MQ fraction is equal to or exceeds half the magnitude of a 1-bit in AC 35. The AC is corrected if rounding results in a carry from AC 9.

Indicators. Floating-point overflow, floating-point trap.

Timing: 2 cycles

Execution. If MQ 9 contains a 1, a carry will be added to AC 35. A carry out of AC 9 increases the char-

acteristic of the AC by 1, causes the fraction of the AC to be shifted right and a 1 to be placed in AC 9. Since the address part of this instruction represents part of the operation code, any modification by an index register may result in changing the operation itself.

FMP — Floating Multiply

Description. The c(Y) are multiplied by the c(MQ). The most significant part of the product appears in the AC and the least significant part appears in the MQ. The product of two normalized numbers is in normalized form. If either of the numbers is not normalized, the product may or may not be in normalized form.

Indicators. Floating-point underflow, floating-point overflow, and floating-point trap.

Timing: 2-5 cycles

Execution

- 1. The C(Y) are placed in the SR and the AC is cleared.
- 2a. If the multiplicand is a normal zero so that $C(SR)_{1-35}$ are equal to zero, the MQ_{1-35} is cleared and the calculator proceeds directly to the next instruction in sequence.
- 2b. If the c (SR) $_{9-35}$ are not equal to zero, the sum of the characteristics in the SR and MQ minus 128 is placed in positions 1-8 of the AC* (Figure 25).
- 3. The c (SR) $_{9-35}$ are multiplied by the c (MQ) $_{9-35}$. The 27 most significant digits of the 54-digit product replace the c (AC) $_{9-35}$ and the 27 least significant digits replace the c (MQ) $_{9-35}$. The sign of the AC is the algebraic sign of the product.
- 4a. If the fraction in the AC is zero, the $C(AC)_{Q, P, 1-35}$ are cleared, yielding a signed normal zero.
- 4b. If the position 9 of the AC contains a zero but the fraction in the AC is not zero, the $C(AC)_{10-35}$ and the $C(MQ)_{9-35}$ are shifted left one position and the characteristic in the AC is reduced by 1.
- 5a. If the AC contains a normal zero, positions 1-8 of the MQ are cleared.
- 5b. If the AC does not contain a normal zero, the $C(MQ)_{1-8}$ are replaced by a characteristic which is 27 less than the characteristic in the AC (*).
- 6. The sign of the MQ is replaced by the sign of the AC.

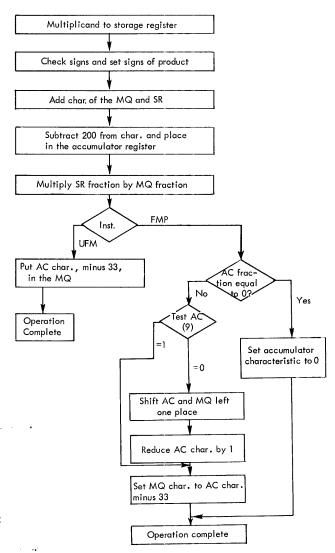

Figure 25. FMP and UFM Flow Chart

UFM — Unnormalized Floating Multiply

Description. This instruction multiplies the floating-point number at Y by the floating-point number in the MQ. The result is not normalized.

Indicators. Floating-point underflow and floating-point overflow; floating-point trap.

Timing: 2-5 cycles

Execution. The same procedure as FMP except that the product is not normalized or zero tested.

Figure 25 shows a flow chart of the FMP and UFM instructions.

FDH — Floating Divide or Halt

Description. The C(AC) are divided by the C(Y). The quotient appears in the MQ and the remainder appears in the AC. If the magnitude of the AC fraction is greater than or equal to twice that of the C(Y) 9-35, or if the magnitude of the C(Y) 9-35 is zero, the divide check indicator is turned on and the computer stops, leaving the dividend in the AC unchanged and a normal zero in the C(MQ). The quotient is in normal form if both the dividend and divisor are in that form. If they are, the magnitude of the ratio of the fraction in the AC to the fractional part of C(Y) is less than two but greater than one-half.

Indicators. Floating-point underflow, floating-point overflow, divide check, and floating-point trap.

Timing: 3-9 cycles

Execution

- 1. The c(y) are placed in the storage register.
- 2. The MQ is cleared.
- 3. The sign of the MQ is made equal to the algebraic sign of the quotient. The sign of the AC remains unchanged throughout so that the signs of the remainder and dividend always agree.
- 4. If the magnitude of the fraction in the AC is greater than or equal to twice the magnitude of the fraction in the SR, or if the fraction in the SR is zero, the divide-check indicator and panel light are turned on, the calculator stops and the dividend is left unchanged in the AC.
- 5. If the fraction in the AC is zero, the $C(AC)_{Q,P,1-35}$ are cleared and the remaining steps are skipped. If s (AC) is minus, the sign is forced plus.
- 6. If the magnitude of the fraction in the AC is greater than or equal to the magnitude of the fraction in the SR, the AC (positions 9-35) is shifted right one position, and the characteristic in the AC is increased by one. The bit in position 35 of the AC enters position 9 of the MQ.
- 7. The characteristic of the AC minus the characteristic of the SR plus 128 is placed in positions 1-8 of the MQ.*

- 8. The fractional part of the dividend, which consists of the $C(AC)_{9-35}$ (and the C(MQ) if the condition of step 6 is met), is divided by the fraction in the sx and the quotient replaces the $C(MQ)_{9-35}$.
- 9. The 27-bit remainder resulting from the division in step 8 replaces the c (AC) $_{8-85}$.
 - 10. The characteristic in the AC is reduced by 27*.

Note: Even though the numbers are not in normalized form, the quotient will be normalized if the ratio above holds. If the fraction in the Ac is zero, a normalized zero will result in the MQ.

FDP — Floating Divide or Proceed

Description. This instruction divides the floating-point number stored in the Ac by the floating-point number located at Y.

Indicators. Floating-point underflow, floating-point overflow, divide check, and floating-point trap.

Timing: 3-9 cycles

Execution. The same procedure as FDH except that if the computer cannot handle the problem, it does not halt but proceeds to the next sequential instruction.

Floating-Point Trap

During the execution of floating-point instructions the resultant characteristic in the Ac and MQ may exceed eight bit positions (result is too large for storage). The capacity is exceeded if the exponent goes beyond +177₈ or below -200₈. Beyond +177₈ is termed overflow while below -200₈ is termed underflow. Overflow and underflow may occur in either the AC or the MQ registers.

To aid the programmer in checking for these conditions, a unique check called *floating-point trap* is used. The computer will, upon sensing an underflow or overflow, put the address plus one of the instruction that caused the condition into the address portion of location 0000.

An identifying code, telling whether an underflow or an overflow occurred and whether the most significant result is in the AC or MQ, is placed in the decrement portion of location 0000. The computer then executes the instruction at location 0010 and proceeds from there. These underflows and overflows are termed *spills*. The decrement positions and meaning of a 1-bit in these positions is:

BIT

POS. MEANING

- 12. Double-precision address error.
- 14. Single-precision divide only (MQ register is not an extension of the AC factor).
- 15. Overflow in either AC or MQ, or both registers.
- 16. Ac factor exceeded-Ac overflow or underflow.
- MQ fraction is excessive—MQ overflow or underflow.

Double-Precision Floating-Point Operations

The IBM 7094 Data Processing System provides high-speed floating-point operations for both single-precision and double-precision numbers. The standard floating-point number format uses eight bits to express an exponent and 27 bits plus a sign position to express the fraction. Double-precision floating-point number format retains the same exponent range but increases the fraction length to 54 bits.

The result of a double-precision operation is a number contained in the accumulator (AC) and the multiplier-quotient (MQ) registers. This number has the same format as the result of a floating-point add instruction. That is, the signs of the AC and MQ are the same, the characteristic in the MQ is 27 less than the AC characteristic, and there are two 27-bit fractions. The format of double-precision operands in core storage is the same, except that the low-order sign and characteristic of both operands do not participate in any of the double-precision instructions.

All double-precision operands brought from core storage must be located so that the high-order portion is in an even-numbered core storage location and the low-order portion of the number is in the next higher (odd) numbered location. If the effective address of a double-precision instruction (except the double store instruction) is odd, the instruction is trapped as with a floating-point trap and bit 12 indicates the error address condition. If the floating-point trap mode indicator is not on, the contents of the odd location are used for both the high-order and low-order portions of the double-precision operation. The word format is:

Characteristic	Fraction	
S, 1 8 9		35
First word (most significant	r)	
	F	
Characteristic	Fraction	
Characteristic	Fraction	35

Word positions 1-8 represent the characteristic, and positions S, 9-35 represent the fraction. The rules for single-precision floating-point apply.

DLD - Double Load

Description. Execution of this instruction places the c(y) and c(y+1) into the AC and MQ registers, respectively.

Indicators. Floating-point trap.

Timing: 2 cycles

DST — Double Store

Description. Execution of this instruction stores the contents of the AC $_{\mathbf{S},\ 1-35}$ in location Y and the contents of MQ $_{\mathbf{S},\ 1-35}$ in location Y + 1.

Indicators. None.

Timing: 3 cycles

DFAD — Double-Precision Floating-Point Add

Description. This instruction algebraically adds the double-precision floating-point number contained in Y and Y+1 to the double-precision floating-point number in the AC and MQ. The most significant portion of the result appears in the AC; the least significant in the MQ. The sign of the sum is the sign of the larger factor. The sum is always normalized whether the original factors were normal or not.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-13 cycles

Execution. The number with the smaller exponent is placed in the AC and MQ and effectively shifted right. Bits shifted past fraction bit 54 (MQ $_{35}$) are lost. If the shift is greater than 63, the AC and MQ are cleared. The low-order portions (MQ and Y + 1)

are added together; the high-order portions (AC and Y) are then added together. The sum appears in the AC and MQ. Normalization, sign, characteristic, and indicator settings are treated as in a floating add operation. The contents of the sense indicator register are destroyed when DFAD is executed.

DUFA — Double-Precision Unnormalized Floating Add

Description. This instruction algebraically adds the double-precision floating-point number contained in Y and Y+1 to the double-precision number contained in the Ac and MQ. The sum is unnormalized.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-9 cycles

Execution. The same as DFAD except the result is not normalized. The contents of the sense indicator register are destroyed when DUFA is executed.

DFSB — Double-Precision Floating-Point Subtract

Description. This instruction algebraically subtracts the double-precision floating-point number contained in Y and Y+1 from the double-precision floating-point number in the AC and MQ, and then normalizes the result.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-13 cycles

Execution. The same as in DFAD except that the sign coming from Y is inverted. The contents of the sense indicator register are destroyed when DFSB is executed.

DUFS — Double-Precision Unnormalized Floating-Point Subtract

Description. This instruction algebraically subtracts the double-precision floating-point number contained

in Y and Y+1 from the double-precision floating-point number in the AC and MQ. The result is not normalized.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-9 cycles

Execution. The same as DFAD except that the sign coming from Y is inverted and the result is not normalized. The contents of the sense indicator register are destroyed when DUFS is executed.

DFAM — Double-Precision Floating-Point Add Magnitude

Description. This instruction algebraically adds the positive magnitude of the double-precision floating-point number contained in Y and Y+1 to the signed double-precision floating-point number in the AC and MQ. The sum is normalized.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-13 cycles

Execution. The same as detail except that the magnitude of the number in Y and Y+1 is used (sign is forced plus). The contents of the sense indicator register are destroyed when deam is executed.

DUAM — Double-Precision Unnormalized Floating-Point Add Magnitude

Description. This instruction algebraically adds the positive magnitude of the double-precision floating-point number contained in Y and Y+1 to the signed double-precision floating-point number in the AC and MQ. The sum is not normalized.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-9 cycles

Execution. The same as DFAD except the magnitude of the number in Y and Y+1 is used (sign forced plus) and no normalizing occurs. The contents of the sense indicator register are destroyed when DUAM is executed.

DFSM — Double-Precision Floating-Point Subtract Magnitude

Description. This instruction algebraically subtracts the magnitude of the double-precision floating-point number contained in Y and Y+1 from the signed double-precision floating-point number in the AC and MQ. The result is normalized.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-13 cycles

Execution. Same as DFAD except the negative magnitude of the c(y) and c(y+1) are used (sign forced minus). The contents of sense indicator register are destroyed when DFSM is executed.

DUSM — Double-Precision Unnormalized Floating-Point Subtract Magnitude

Description. This instruction algebraically subtracts the magnitude of the double-precision floating-point number contained in Y and Y+1 from the signed double-precision floating-point number in the AC and MQ. The result is not normalized.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-9 cycles

Execution. Same as DFAD except the negative magnitude of the c(y) and c(y+1) are used and the result is not normalized. The contents of the sense indicator register are destroyed when DUSM is executed.

DFMP — Double-Precision Floating-Point Multiply

Description. The C(Y) and C(Y+1) are multipled by the C(AC) and C(MQ). The most significant part of

the product appears in the Ac and the least significant in the MQ. The product of two normalized numbers is in normalized form. If either of the numbers is not normalized, the product may be in unnormalized form.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-11 cycles

Execution

- 1. If the multiplicand or the multiplier is a normal 0, or the high-order fractions of both are 0, the Ac and MQ are cleared to a signed normal 0 and the computer takes the next sequential instruction.
- 2. If item 1 is not true, three multiplications are performed: $AC \times C(Y)$, $MQ \times C(Y)$, and $AC \times C(Y+1)$. The low-order parts of the products $[MQ \times C(Y)]$ and $AC \times C(Y+1)$ are discarded, and the remaining high-order parts are added to the low-order part of the product $[AC \times C(Y)]$.
- 3. If both product fractions in AC and MQ are 0, the characteristics of the AC and MQ are cleared, giving a signed normal 0.
- 4. If the product is not 0 but position 9 of the AC is 0, $c(AC)_{10-35}$ and $c(MQ)_{9-35}$ are shifted left one position and the characteristic of the AC is reduced by 1.
- 5. The settings of signs, characteristics, and indicators is the same as with a floating-point add operation.

The contents of the sense indicator register are destroyed when DFMP is executed.

DUFM — Double-Precision Unnormalized Floating-Point Multiply

Description. This instruction multiplies the double-precision floating-point number at Y and Y+1 by the double-precision floating-point number in the AC and MQ. The result is not normalized.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 2-11 cycles

Execution. Same as DFMP except the result is not normalized. The contents of the sense indicator register are destroyed when DUFM is executed.

DFDH — Double-Precision Floating-Point Divide and Halt

Description. This instruction divides the double-precision floating-point number in the AC and MQ by the double-precision floating-point number in Y and Y+1. The quotient is a double-precision floating-point number in the AC and MQ. If the magnitude of the AC fraction (at the start of either divide operation) is greater than or equal to twice that of the $C(Y)_{9-35}$, or if the $C(Y)_{9-35}$ is zero, the divide check indicator is turned on and the computer halts. The quotient is in normal form if both the dividend and divisor are in normal form. The quotient will always be in normal form.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 3-19 cycles

Execution. If the high-order and low-order fractions of the two operands are labeled A(AC), B(MQ), C C(Y), and D C(Y + 1), to get:

$$\frac{A+B\times 2^{-27}}{C+D\times 2^{-27}} = Q_1 + Q_2 \times 2^{-27}$$

the following formulas are used:

$$\frac{A + B \times 2^{-27}}{C} = Q_1 + \frac{R \times 2^{-27}}{C}$$
$$\frac{(R - Q_1 \times D) 2^{-27}}{C} = Q_2 \times 2^{-27} + \dots$$

 $Q_1 + Q_2 \times 2^{-27}$ = Final quotient in AC and MQ.

Since this procedure contains two floating-point divide operations, a divide check could occur at two different times: (1) If a divide check occurs on the first division, the dividend remains unchanged and the sense indicator register is cleared. (2) If a divide check occurs on the second division, the AC fraction contains (R -- $Q_1 \times D$), and the sense register contains the quotient (Q_1) of the first division. The overflow or underflow indication will be lost if a divide check occurs. The contents of the sense indicator register are destroyed when DFDH is executed.

DFDP — Double-Precision Floating-Point Divide and Proceed

Description. This instruction divides the double-precision floating-point number in the AC and MQ by the double-precision floating-point number located at Y and Y+1.

Indicators. Floating-point underflow, overflow, and trap.

Timing: 3-19 cycles

Execution. Same as DFDH except that instead of halting on divide check, the computer proceeds to the next sequential instruction. The contents of the sense indicator register are destroyed when DFDP is executed.

Shifting Operations

Shift instructions are used to move the contents of the AC and/or the MQ either to the right or the left of their original positions. With the exception of the ROTATE MQ LEFT instruction, zeros are automatically introduced in the vacated positions of a register. Thus, a shift larger than the bit capacity of the register will cause the contents of the register to be replaced by zeros.

When a shift instruction is interpreted, the amount of the shift is determined by bit positions 28-35 of the instruction. This provides a maximum shift of 377 places. Any number larger than 377 is interpreted as modulo 400. By modulo 400 is meant that, given any shift count, the actual number of positions shifted will be the remainder after dividing the shift count by 400.

All shift instructions are subject to address modification through indexing. Shifting a number in a register is equivalent to multiplying or dividing it by a power of 2 (as long as none of the significant bits is lost).

In the following description of the shift instructions, the number of positions to be shifted is specified by "positions 28-35." With indexing, this shift is modified by positions 10-17 of the specified index register or registers.

ALS — Accumulator Left Shift

Description. This instruction causes the C(AC)_{Q, P, 1-35} to be shifted left the number of places specified in positions 28-35 of the address portion of the instruction. The sign position is unchanged.

Indicators. AC overflow.

Timing: 1-4 cycles

Execution. If a non-zero bit is shifted into position P from position 1, the AC overflow indicator is turned on. Bits shifted past position Q are lost. Vacated positions are filled with zeros (Figure 26).

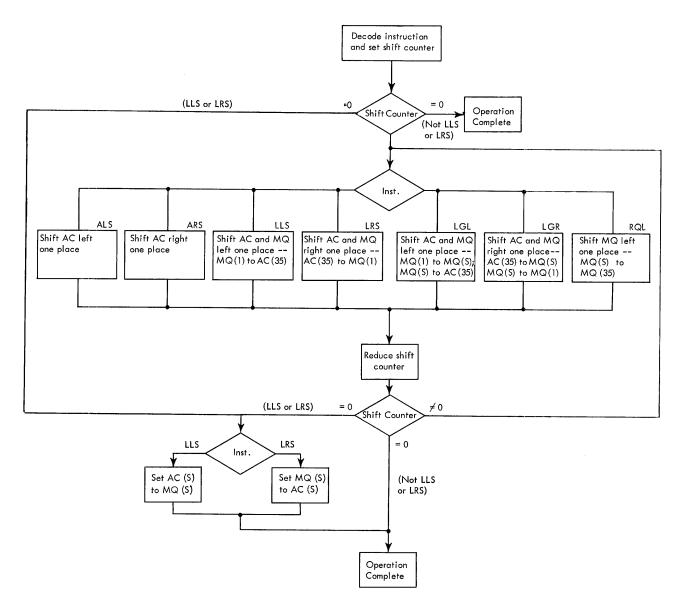

Figure 26. ALS, ARS, LLS, LRS, LGL, LGR, and RQL Flow Chart

ARS — Accumulator Right Shift

Description. The C (AC) Q, P, 1-35 are shifted right the number of places specified in positions 28-35 of the address portion of the instruction. The sign position is unchanged.

Indicators. None.

Timing: 1-4 cycles

Execution. Bits shifted past position 35 of the accumulator are lost. Bits shifted from Q enter P and bits from P enter position 1. Vacated positions are filled with zeros (Figure 26).

LLS - Long Left Shift

Description. The C(AC)_{Q, P, 1-35} and the C(MQ)₁₋₃₅ are treated as one register. The contents of these registers are shifted left the number of places specified in positions 28-35 of the address portion of the instruction. The MQ sign position is unchanged and the sign of the AC is made to agree with it.

Indicators. AC overflow.

Timing: 1-7 cycles

Execution. Bits enter position 35 of the AC from position 1 of the MQ. If a non-zero bit is shifted into or through position P, the AC overflow indicator is turned on. Bits shifted past position Q are lost. Positions vacated are filled with zeros (Figure 26).

LRS - Long Right Shift

Description. The $C(AC)_{Q, P, 1-35}$ and the $C(MQ)_{1-35}$ are treated as one register. The contents of these registers are shifted right the number of places specified in positions 28-35 of the address portion of the instruction. The AC sign is unchanged and the sign of the MQ is made to agree with it.

Indicators. None.

Timing: 1-7 cycles

Execution. Bits enter position 1 of the MQ from position 35 of the AC. Bits shifted past position 35 of the MQ are lost. Vacated positions are filled with zeros (Figure 26).

Figure 26 shows the flow chart for the ARS, ALS, LLS, and LRS instructions.

LGL — Logical Left Shift

Description. The C (AC) Q, P, 1-35 and the C (MQ) 8, 1-35 are treated as one register. Their contents are shifted left the number of places specified in positions 28-35 of the address portion of the instruction. The sign of the AC is unchanged.

Indicators. AC overflow.

Timing: 1-7 cycles

Execution. Bits enter position S of the MQ from position 1 of the MQ. Bits from MQ (s) then enter position 35 of the accumulator. If a non-zero bit is shifted into or through position P of the AC, the AC overflow indicator is turned on. Bits are shifted from P to Q and any bits shifted from Q are lost. Vacated positions are filled with zeros (Figure 26).

LGR — Logical Right Shift

Description. The c (Ac) Q, P, 1-35 and the c (MQ) S, 1-35 are treated as one register. Their contents are shifted right the number of places specified in positions 28-35 of the address portion of the instruction. The sign of the Ac is unchanged.

Indicators. None.

Timing: 1-7 cycles

Execution. Bits enter position S of the MQ from position 35 of the AC. Bits enter MQ 1 from MQ (s). Bits shifted past position 35 of the MQ are lost. Vacated positions are filled with zeros (Figure 26).

RQL — Rotate MQ Left

Description. The C (MQ) are shifted left the number of places specified by positions 28-35 of the address portion of the instruction. The instruction shifts position S into position 35, and thus the register becomes a circular one.

Indicators. None.

Timing: 1-4 cycles

Execution. Bits are rotated from position 1 of the MQ to position S, and from position S to position 35. No bits are lost (Figure 26).

Word Transmission Operations

The operations described in this section are concerned with the movement of words or parts of words from one core location or register to another.

LDQ - Load MQ

Description. This instruction places the contents of Y into the MQ. The c(y) are unchanged.

Indicators. None. Timing: 2 cycles

STQ - Store MQ

Description. This instruction places the contents of the MQ into the specified Y location. The C(MQ) remain unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 27.

SLQ - Store Left Half MQ

Description. The $C(MQ)_{S, 1-17}$ replace the $C(Y)_{S, 1-17}$. The C(MQ) and the $C(Y)_{18-35}$ are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 27.

STO — Store

Description. The $C(AC)_{S, 1-35}$ replace the C(Y). The C(AC) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 27.

SLW — Store Logical Word

Description. The $C(AC)_{P,1-35}$ replace the C(Y). The C(AC) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 27.

STP — Store Prefix

Description. The $C(AC)_{P, 1, 2}$ replace the $C(Y)_{8, 1, 2}$. The $C(Y)_{3-35}$ and the C(AC) are unchanged.

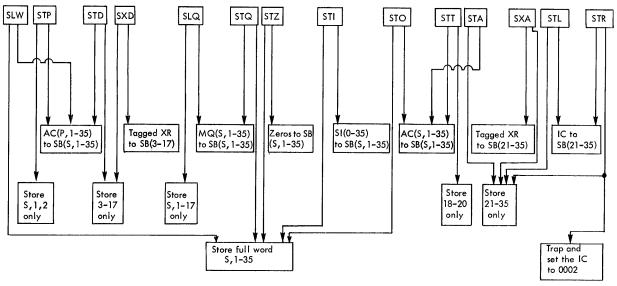

Figure 27. Data Flow Chart for Store Instructions

Indicators. None.Timing: 2 cycles

Execution. See Figure 27.

STD — Store Decrement

Description. The c (AC) $_{3-17}$ replace the c (Y) $_{3-17}$. The C (Y) $_{8, 1, 2, 18-35}$ and the c (AC) are unchanged.

Indicators. None. Timing: 2 cycles

Execution. See Figure 27.

STT — Store Tag

Description. The $C(AC)_{18-20}$ replace the $C(Y)_{18-20}$. The $C(Y)_{S, 1-17, 21-35}$ and the C(AC) remain unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 27.

STA — Store Address

Description. The $C(AC)_{21-35}$ replace the $C(Y)_{21-35}$. The $C(Y)_{S, 1-20}$ and the C(AC) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 27.

STL — Store Instruction Location Counter

Description. The location of the STL instruction plus 1 replaces the $C(Y)_{21-35}$. The $C(Y)_{8, 1-20}$ are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. Instruction counter contents to address switches. Address switches to the storage register bus. Storage register (21-35) to storage. See Figure 27.

STR — Store Location and Trap

Description. The location of the STR instruction, plus one, replaces positions 21-35 of location 0000. The computer then takes its next instruction from location 0002. The contents of positions 3-35 of this instruction are not interpreted by the computer. See XEC instruction.

Indicators. None.

Timing: 2 cycles

Execution.

Note: Conflicts may arise when the computer is operated in the trapping mode. This instruction, transfers in the trap mode, and floating-point trap, all use location 0000. See Figure 27.

STZ - Store Zero

Description. The $C(Y)_{1-35}$ are replaced by zeros and the $C(Y)_S$ are made plus.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 27.

XCA — Exchange AC and MQ

Description. The $C(AC)_{8, 1-35}$ are exchanged with the $C(MQ)_{8,1-35}$. Positions P and Q of the AC are cleared.

Indicators. None.

Timing: 1 cycle

Execution. See Figure 28.

XCL — Exchange Logical AC and MQ

Description. The $C(AC)_{P, 1-35}$ are exchanged with the $C(MQ)_{S, 1-35}$. Positions S and Q of the AC are cleared.

Indicators. None.

Timing: 1 cycle

Execution. See Figure 28.

ENK — Enter Keys

Description. This instruction places the contents of 36 panel input switches into the C(MQ). When a panel input switch is down it represents a 1; when it is up, it represents a zero.

Indicators. None.

Timing: 2 cycles

Execution. Since the address part of this instruction contains part of the operation code for this instruction, any address modification by an index register may result in the changing of the operation itself.

Control Instructions

Instructions which govern the flow of a program, and in particular those which cause an alteration in the computer's normal process of taking its instructions from sequential locations, are called *control instructions*.

Unconditional transfer instructions specify the location "Y" from which the computer is to take the

next instruction. Conditional transfer instructions also specify a location Y. However, whether the computer takes its next instruction from Y or the next sequential location depends upon the outcome of a test. This test is specified by the operation code of the instruction.

Test instructions are similar to conditional control instructions in that they cause some test to be performed. Unlike conditional instructions, however, test instructions do not specify a location Y to which control may be transferred. Instead, the alternative location to which control may be transferred is fixed relative to the location of the test instruction.

NOP - No Operation

Description. This instruction causes the computer to take the next instruction in sequence.

Indicators. None.

Timing: 2 cycles

HPR — Halt and Proceed

Description. This instruction causes the computer to halt. The ic contains the location of the next se-

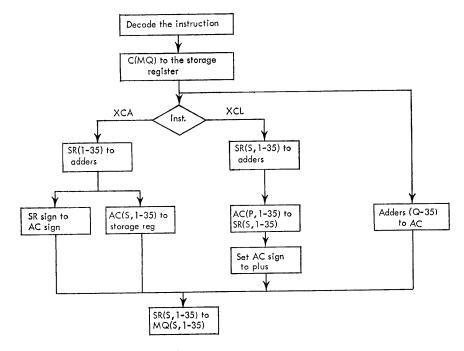

Figure 28. xca and xcl Flow Chart

quential instruction. When the start key on the operator's console is depressed, the computer proceeds and executes the next sequential instruction.

Indicators. None. Timing: 2 cycles

HTR — Halt and Transfer

Description. This instruction causes the computer to halt. The IC contains the location of the HTR instruction. Depression of the start key, on the operator's console, causes the computer to transfer to location Y and execute that instruction.

Indicators. Trap Mode.

Timing: 2 cycles

XEC — Execute

Description. This instruction causes the computer to perform or "execute" the instruction at location Y.

Indicators. None.

Timing: 1 cycle

Execution. Since the instruction counter is not altered (when Y contains any instruction other than a successful transfer or test instruction), the program advances to the next sequential instruction following the execute instruction after performing the instruction at location Y. If location Y contains a transfer instruction, it will be executed and program control will be altered from the sequential process. If location Y contains a test instruction, the instruction following execute will be located relative to the execute rather than the test instruction. Thus, any instruction which changes the instruction counter (STR, TRA, DCT, etc.) will alter program control when that instruction is executed by xec.

TRA — Transfer

Description. This instruction causes the computer to take its next instruction from location Y and proceed from there.

Indicators. Trap Mode.

Timing: 1 cycle

Execution. See Figure 29.

ETM — Enter Trapping Mode

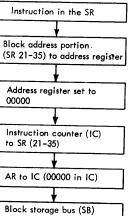

Description. This instruction causes the computer to enter the transfer trapping mode. The transfer trapping indicator on the operator's console is turned on.

Indicators. Trap Mode.

Timing: 2 cycles

Execution. When the computer is in the trapping mode and any transfer instruction except a TTR is executed, the location of the transfer instruction replaces the address part of location 00000 whether the condition for transferring is met or not. The computer executes all parts of the transfer operation normally, except that if the transfer condition is met, the computer takes its next instruction from location 00001. Only instructions which have "transfer" in their title are affected by the transfer trapping mode.

TRA in Trap Mode

SR to SB and Advance IC to 00001

Figure 29. TRA Flow Chart

Address modification may change the operation, since positions 23-35 of the instruction are a part of the operation code.

LTM - Leave Trapping Mode

Description. This instruction turns off the trap mode indicator and causes the computer to leave the transfer trapping mode. Transfer instructions, therefore, will not be trapped again until an ETM operation is executed.

Indicators. Trap Mode.

Timing: 2 cycles

Execution. The computer operates in the trapping mode until either a LEAVE TRAPPING MODE OPERATION is executed or the clear or reset key on the operator's console is depressed. Since positions 23-35 represent part of the operation code of this instruction, any modification by an index register may result in the changing of the operation itself.

TTR - Trap Transfer

Description. This instruction causes the computer to take its next instruction from location Y and to proceed from there whether in the transfer trap mode or

not. This makes it possible to have an unconditional transfer in the transfer trapping mode.

Indicators. None.

Timing: 1 cycle

TZE - Transfer on Zero

Description. If the $C(AC)_{Q,P,1-35}$ are zero, the computer takes its next instruction from location Y and proceeds from there. If they are not zero, the next sequential instruction is taken.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 30.

TNZ — Transfer on No Zero

Description. If the $C(AC)_{Q,P,1-35}$ are not zero, the computer takes its next instruction from location Y and proceeds from there. If they are zero, the next sequential instruction is taken.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 30.

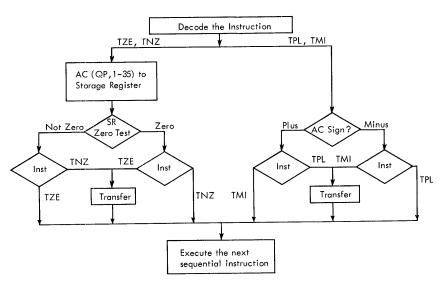

Figure 30. TNZ, TZE, TPL, and TMI Flow Chart

TPL -- Transfer on Plus

Description. If the sign position of the AC is positive, the computer takes its next instruction from location Y and proceeds from there. If the sign position is negative, the computer takes the next sequential instruction.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 30.

TMI - Transfer on Minus

Description. If the sign position of the AC is negative, the computer takes its next instruction from location Y and proceeds from there. If the sign position is positive, the computer takes the next sequential instruction.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 30.

TOV — Transfer on Overflow

Description. If the AC overflow indicator is on, it is turned off and the computer takes its next instruction from location Y. If the indicator is off, the computer takes the next sequential instruction.

Indicators. Ac overflow, trap mode.

Timing: 1 cycle

Execution. See Figure 31.

TNO — Transfer on No Overflow

Description. If the AC overflow indicator is off, the computer takes its next instruction from location Y. If the indicator is on, it is turned off and the computer takes the next sequential instruction.

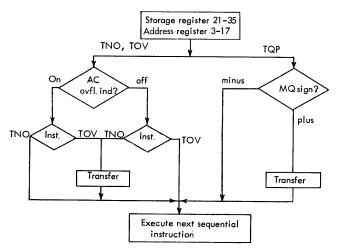

Figure 31. Tov, TNO, and TQP Flow Chart

Indicators. Ac overflow, trap mode.

Timing: 1 cycle

Execution. See Figure 31.

TQP — Transfer on MQ Plus

Description. If the sign position of the MQ is plus, the computer takes its next instruction from location Y. If the sign position is negative, the computer takes the next sequential instruction.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 31.

TQO — Transfer on MQ Overflow

Description. This instruction is a conditional transfer when the computer is operating in the 704 floating-point mode. If the MQ overflow indicator is on, the computer takes its next instruction from location Y and turns the indicator off.

Indicators. MQ overflow.

Timing: 1 cycle

Execution. If this instruction is executed while the computer is in the normal mode, it is treated as a 1 cycle no-operation whether the MQ overflow indicator is on or not.

TLQ — Transfer on Low MQ

Description. If the c(MQ) are algebraically less than the c(AC), the computer takes its next instruction from location Y. If the c(MQ) are algebraically greater than or equal to the c(AC), the computer takes the next sequential instruction. Note: a plus zero is algebraically greater than a minus zero.

Indicators. Trap mode.

Timing: 2 cycles

Execution. See Figure 32.

TSX — Transfer and Set Index

Description. This instruction places the 2's complement of the core address of the TSX(IC) in the specified index register (T). The computer takes its next instruction from location Y at all times. Note: Subtracting the 2's complement of a number is equivalent to adding the number.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 29.

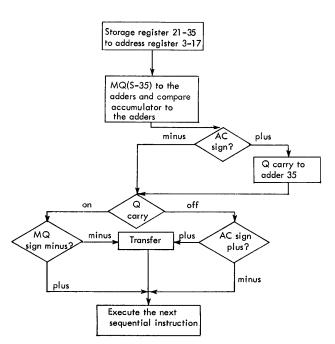

Figure 32. TLQ Flow Chart

TXI - Transfer with Index Incremented

Description. This instruction adds the decrement (D) to the contents of the specified index register (T) and replaces the contents of the index register with the resulting sum. The computer then takes its next instruction from location Y at all times.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 33.

TXH - Transfer on Index High

Description. If the number in the specified index register (T) is greater than the decrement (D), the computer takes its next instruction from location Y. If the number in the specified index register is less than or equal to D, the computer takes the next sequential instruction. With a tag of zero, no transfer occurs.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 34.

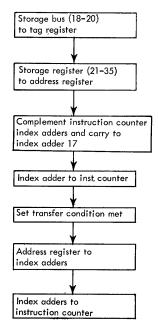

Figure 33. TXI Flow Chart

Instruction	XR > D	$XR \leq D$
TIX	Takes next instruction from location (Y) and decrements XR by value of D	Take next sequential instruction
TXI	Takes next instruction from location (Y) and increments XR by value of D (complement add)	Not applicable; unconditional transfer
TXH	Takes next instruction from location (Y)	Take next sequential instruction
TXL	Takes next sequential instruction	Take next instruction from location (Y)
XNX	Decrement XR by value of D and take next sequential instruction	Take next instruction from location (Y)

Figure 34. Index Transfers

TXL — Transfer on Index Low or Equal

Description. If the contents of the index register specified by T are less than or equal to D, the computer takes its next instruction from location Y. If C(XR) specified by T are greater than D, the computer takes the next sequential instruction. With a tag of zero, a transfer occurs.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 34.

TIX — Transfer on Index

Description. If the c(xR) specified by T are greater than D, the number in the index register is reduced by D and the computer takes its next instruction from Y. If c(xR) specified by T are less than or equal to

D, the C(XR) are unchanged and the computer takes the next sequential instruction. With a tag of zero, no transfer occurs.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 34.

TNX — Transfer on No Index

Description. If the C(XR) specified by T are equal to or less than D, the C(XR) are unchanged and the computer takes its next instruction from Y. If C(XR) specified by T are greater than D, the C(XR) are reduced by D and the computer takes the next sequential instruction. With a tag of zero, a transfer occurs.

Indicators. Trap mode.

Timing: 1 cycle

Execution. See Figure 34.

PSE - Plus Sense

Description. This instruction provides a means of testing the status of the sense switches and of turning on or off the sense lights on the operator's console. The instruction also permits the transmission of an impulse to or from the exit or entry hubs on the printer or card punch control panels. Address modification may cause the operation code to be changed.

Indicators. Sense indicators and switches.

Timing: 2 cycles

Execution. The address part (23-35) of this instruction determines whether a light, switch, printer, or card punch is being sensed. Further, it determines which light, switch, or hub is sensed. The octal addresses for sense instructions are:

0140	Turns off all sense lights on the operator's console.
SLN 0141- 0144	Turn on sense lights 1, 2, 3 or 4, respectively, on the console.
SWT	
0161- 0166	Test sense switches on the console. If the corresponding switch is down (on), the computer skips the next instruction and proceeds from there. If the sense switch is up (off), the computer takes the next sequential instruction.

SPU	
1341- 1342 (A) 2341- 2342 (B)	An impulse will appear at the specified exit hub of the card punch control panel attached
3341- 3342 (C) 4341- 4342 (D)	to appropriate data channel. Hubs are numbered 1 and 2.
5341 - 5342 (E) 6341 - 6342 (F)	
7341 - 7342 (G) 10341 - 10342 (H)	
SPT	
1360 (A) 2360 (B)	If an impulse is present at the sense entry hub of the printer control panel, the com-
3360 (C) 4360 (D)	puter skips the next instruction and proceeds from there. If no impulse is present,
5360 (E) 6360 (F)	the computer takes the next sequential in- struction.
7360 (G)	Struction.
10360 (H) SPR	
1361- 1372 (A) 2361- 2372 (B)	The computer causes an impulse to appear at the specified hub on the control panel of
3361 - 3372 (C) 4361 - 4372 (D)	the printer attached to that particular data channel.
5361- 5372 (E)	chamer.
6361 - 6372 (F) 7361 - 7372 (G)	
10361-10372 (H)	

MSE — Minus Sense (Sense Light Test)

-0760			Т	
5, 1	11 12	17 18	-20 21-22 23	35

Description. This instruction provides a means of testing the status of the sense lights on the operator's console. The lights may be turned on by a PSE instruction with an address of 0141 to 0144. Address modification may cause the operation code to be changed.

Indicators. Sense lights.

Timing: 2 cycles

Execution. The addresses of the four sense lights are 0141 to 0144. If the corresponding sense light is on, the light is turned off and the computer skips the next instruction and proceeds from there. If the light is off, the computer executes the next sequential instruction.

BTT — Beginning of Tape Test

Description. This instruction is used to test the status of data channel beginning-of-tape indicators. The channel whose indicator is to be tested is specified by the address portion (Y) of the BTT instruction. Address modification may cause the operation code to be changed. The addresses for the channels are:

Data	channel	Α	1000
Data	channel	В	2000
Data	channel	\mathbf{C}	3000
Data	channel	D	4000
Data	channel	\mathbf{E}	5000
Data	channel	F	6000
Data	channel	G	7000
Data	channel	H	10000

Indicators. All beginning-of-tape indicators.

Timing: 2 cycles

Execution. If the beginning-of-tape indicator for data channel Y is on, the computer takes the next sequential instruction, and the indicator is turned off. If the beginning-of-tape indicator is off, the computer skips the next instruction and proceeds from there. The beginning-of-tape indicator is turned on by a backspace record or backspace file instruction given to a tape unit that is positioned at its load point. See Figure 35.

ETT — End of Tape Test

Description. This instruction is used to test the status of data channel end-of-tape indicators. The channel whose indicator is to be tested is specified by the address portion of the ETT instruction. The addressing system is the same as specified for the BTT instruction. Address modification may cause the operation code to be changed.

Indicators. End-of-tape indicators.

Timing: 2 cycles

Execution. If the end-of-tape indicator for data channel Y is on, the computer takes the next sequential instruction and turns the indicator off. If the

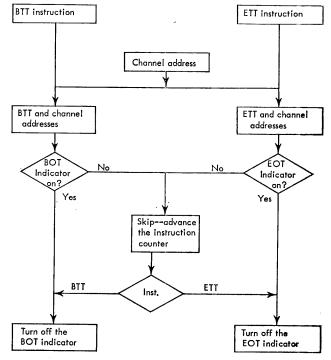

Figure 35. BTT and ETT Flow Chart

indicator is off, the computer skips the next instruction and proceeds from there. The end-of-tape indicator is turned on when either a write select or a write end of file causes the end-of-tape marker to be passed over. See Figure 35.

IOT - Input-Output Check Test

Description. If the 1-0 check indicator is on, the indicator is turned off and the computer takes the next sequential instruction. If the indicator is off, the computer skips the next instruction and proceeds from there. Any address modification may result in the changing of the operation itself.

Indicators. 1-0 check.

Timing: 2 cycles

Execution. The 1-0 check indicator will be turned on by any of the following conditions:

- 1. If a write CRT or drum select instruction is executed and the computer is not in the select trap mode.
- 2. If COPY, COPY AND ADD LOGICAL, OF LOCATE DRUM ADDRESS are executed when the computer is not in the copy trap mode.
- 3. If a reset and load channel or a load channel is executed and the specified channel is not selected.
- 4. If, when writing, a channel data register has not been loaded with a word from storage by the time its contents are to be sent to the output unit.
- 5. If, when reading, a channel data register has not stored its contents by the time new data are to be sent from an input unit. See Figure 36.

PBT - P-Bit Test

Description. If the C (AC) P is a 1, the computer skips the next instruction and proceeds from there. If P contains a 0, the computer takes the next sequential instruction. Address modification may result in the changing of the instruction itself.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 36.

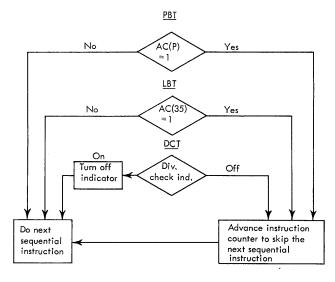

Figure 36. PBT, LBT, and DCT Flow Chart

LBT - Low-Order Bit Test

Description. If the c(Ac)₃₅ is a 1, the computer skips the next instruction and proceeds from there. If 35 is a 0, the computer takes the next sequential instruction. Address modification may result in the changing of the instruction.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 36.

DCT - Divide Check Test

Description. If the indicator is on, it is turned off and the computer takes the next sequential instruction. If the indicator is off, the computer skips the next instruction and proceeds from there. Address modification may result in the changing of the instruction itself.

Indicators. Divide check.

Timing: 2 cycles

Execution. See Figure 36.

ZET — Storage Zero Test

Description. If the $C(Y)_{1-35}$ are 0, the computer skips the next instruction and proceeds from there. If the $C(Y)_{1-35}$ are not zero, the computer takes the next sequential instruction. The C(Y) are not changed.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 37.

NZT — Storage not Zero Test

Description. If the $c(y)_{1-35}$ are not 0, the computer skips the next instruction and proceeds from there. If the $c(y)_{1-35}$ are 0, the computer takes the next sequential instruction. The c(y) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 37.

CAS — Compare Accumulator with Storage

Description. If the c(AC) are algebraically greater than the c(Y), the computer takes the next sequential instruction. If the c(AC) are algebraically equal to the c(Y), the computer skips the next instruction and proceeds from there. If the c(AC) are algebraically less

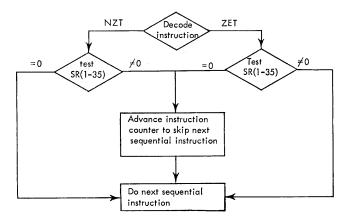

Figure 37. NZT and ZET Flow Chart

than the c(y) the computer skips the next two instructions and proceeds from there.

Indicators. None.

Timing: 2 cycles

Execution. Note: Two numbers are considered algebraically equal if the magnitudes and signs of both are equal. A plus zero is algebraically greater than a minus zero.

LAS — Logical Compare Accumulator with Storage

Description. The $C(AC)_{Q,P,1-35}$ are treated as an unsigned 37-bit number and are compared with the $C(Y)_{S,1-35}$ which are treated as an unsigned 36-bit quantity. If the $C(AC)_{Q,P,1-35}$ are greater than the C(Y), the computer takes the next sequential instruction. If the $C(AC)_{Q,P,1-35}$ are equal to the C(Y), the computer skips the next instruction and proceeds from there. If the $C(AC)_{Q,P,1-35}$ are less than the C(Y), the computer skips the next two instructions and proceeds from there.

Indicators. None.

Timing: 2 cycles

FOR THE FOLLOWING control operations that refer to data channels, the description of the operation is given for channel A. For the other channels, the operation code and the title are given.

TCOA - Transfer on Channel A in Operation

Description. If channel A is in operation, the computer takes its next instruction from location Y. If the channel is not in operation, the computer takes the next sequential instruction, and the operation of the channel is not affected. The channel is in operation as long as a select register contains information. See Figure 38.

Indicators. Trap.

Timing: 1 cycle

INSTRUCTION	CODE	NAMI				
ТСОВ	-	Transfer of		D	in	Operation
						-
TCOC	+0062	Transfer or	ı Channel	C	in	Operation
TCOD	+0063	Transfer or	ı Channel	D	in	Operation

TEFH	-0033	Transfer on	Channel	Н	End	of	File

Index Register Transmission Operations

Operations that load, place or store the contents of index registers always involve one or more index registers and either the address or decrement field of some location in storage or the accumulator register.

The following 15-bit fields may serve as one of the agents in an index transmission operation: the address or decrement of the accumulator, the address or decrement of any location in storage, or the address part of the index transmission instruction itself. In addition, the number involved may be placed in the specified index register in either true or complement form, or the number may be taken from the specified index register in either true or complement form.

Indexing operations may be accomplished in two modes in the 7094. Multiple tag mode (three index registers) is compatible with the 7090 system and is the mode that the 7094 is in following "power on" or a clear operation. Seven index register mode provides seven index registers for use singly and can be

entered by the leave multiple tag mode (LMTM) instruction.

In multiple tag mode, single index registers or combinations of index registers may be specified. If more than one register is specified in an unloading operation, the register contents are or'ed together to produce the effective number. or'ing matches the registers position-for-position. If there is a 1 bit in either or both of the register positions being or'ed, the result is a 1 bit. For example:

xr 1	101100
xr 2	011000
Result	111100

If more than one index register is specified in a loading operation, the data are loaded into all registers specified. In the seven index mode, the seven index registers use all combinations of the tag bits for individual index register addresses; therefore, the presence of two or three tag bits does not mean the or'ing together of the addressed index register contents.

EMTM — Enter Multiple Tag Mode

Description. Execution of this instruction places the computer in the 7090 multiple tag mode, allows multiple tagging, and restricts program usage to index registers A (xR1), B (xR2), and C (xR4). It also turns on the multiple tag mode indicator.

Indicators. Multiple tag mode.

Timing: 2 cycles

Execution. Since the address part of this instruction is a part of the operation code, address modification may result in changing the instruction itself. The computer is placed in operation with three index registers by execution of this instruction, by a power on, or a clear operation. The multiple tag mode indicator is not affected by reset or load key depression.

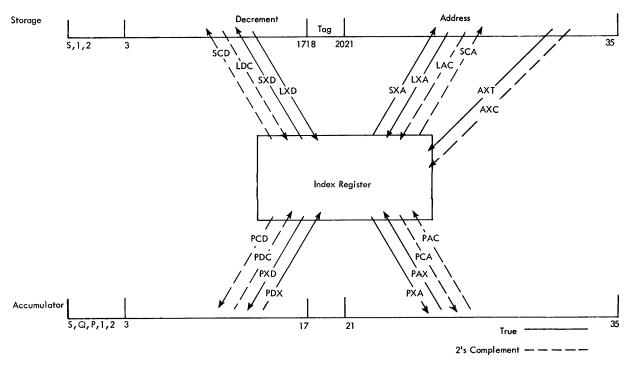

Figure 39. Index Register Transmission Operations

LMTM - Leave Multiple Tag Mode

Description. Execution of this instruction turns off the multiple tag mode indicator and places the computer in operation with seven index registers.

Indicators. Multiple tag mode.

Timing: 2 cycles

Execution. Since the address part of this instruction is a part of the operation code, address modification may result in changing the instruction itself.

PCA - Place Complement of Index in Address

Description. The entire accumulator is cleared and the 2's complement of the contents of the specified index register is placed in the address part of the accumulator (AC 21-35). With a tag of 0, the C(AC) are set to zeros. See Figure 39.

Indicators. None.

Timing: 1 cycle

PCD - Place Complement of Index in Decrement

Description. The entire accumulator is cleared and the 2's complement of the contents of the specified index register is placed in the decrement part of the accumulator (AC 3-17). With a tag of 0, the C(AC) are set to zeros. See Figure 39.

Indicators. None.

Timing: 1 cycle

SCA - Store Complement of Index in Address

Description. The $C(Y)_{21-35}$ are replaced by the 2's complement of the contents of the specified index

register. The $C(Y)_{8, 1-20}$ remain unchanged. A tag of zero results in zeros stored in $C(Y)_{21-35}$. See Figure 39.

Indicators. None.

Timing: 2 cycles

SCD — Store Complement of Index in Decrement

Description. The $C(Y)_{3-17}$ are replaced by the 2's complement of the contents of the specified index register. The $C(Y)_{8, 1, 2, 18-35}$ remain unchanged. A tag of zero results in zeros stored in $C(Y)_{3-17}$. See Figure 39.

Indicators. None.

Timing: 2 cycles

LXA — Load Index from Address

Description. The $c(y)_{21-35}$ replace the contents of the specified index register. The c(y) are unchanged. A tag of zero results in no-operation.

Indicators. None.

Timing: 2 cycles.

Execution. See Figure 39.

LAC — Load Complement of Address in Index

Description. The 2's complement of the $C(Y)_{21-85}$ replaces the contents of the specified index register. The C(Y) are unchanged. A tag of zeros results in nooperation.

Indicators. None.

Timing: 2 cycles.

Execution. See Figure 39.

LXD - Load Index from Decrement

Description. The $c(y)_{3-17}$ replace the contents of the specified index register. The c(y) are unchanged. A tag of zero results in no-operation.

Indicators. None. Timing: 2 cycles.

Execution. See Figure 39.

LDC — Load Complement of Decrement in Index

Description. The 2's complement of the $c(y)_{3-17}$ replaces the contents of the specified index register. The c(y) are unchanged. A tag of zero results in nooperation.

Indicators. None.

Timing: 2 cycles.

Execution. See Figure 39.

AXT - Address to Index True

Description. Positions 21-35 of this instruction replace the contents of the specified index register. The instruction is unchanged. A tag of zero results in no-operation.

Indicators. None.

Timing: 1 cycle

Execution. See Figure 39.

AXC — Address to Index Complemented

Description. The 2's complement of positions 21-35 of this instruction replaces the contents of the speci-

fied index register. The instruction is unchanged. A tag of zero results in no-operation.

Indicators. None.

Timing: 1 cycle

Execution. See Figure 39.

PAX - Place Address in Index

Description. The $C(AC)_{21-35}$ replace the contents of the specified index register. The C(AC) are unchanged. A tag of zero results in no-operation.

Indicators. None.

Timing: 1 cycle

Execution. See Figure 39.

PAC — Place Complement of Address in Index

Description. The 2's complement of the C(AC)₂₁₋₃₅ replaces the contents of the specified index register. The C(AC) are unchanged. A tag of zero results in no-operation.

Indicators. None.

Timing: 1 cycle

Execution. See Figure 39.

PXA — Place Index in Address

Description. The entire accumulator is cleared and the contents of the specified index register are placed in the address part of the AC_{21-35} . With a tag of 0 the C (AC) are set to zeros.

Indicators. None.

Timing: 1 cycle.

Execution. See Figure 39.

PXD - Place Index in Decrement

Description. The entire accumulator is cleared and the contents of the specified index register are placed in the decrement part of the AC₃₋₁₇. With a tag of 0, the C(AC) are set to zeros.

Indicators. None. Timing: 1 cycle.

Execution. See Figure 39.

PDX — Place Decrement in Index

Description. The $C(AC)_{3-17}$ replace the contents of the specified index register. The C(AC) are unchanged. A tag of zero results in no-operation.

Indicators. None. Timing: 1 cycle

Execution. See Figure 39.

PDC — Place Complement of Decrement in Index

Description. The 2's complement of the $C(AC)_{3-17}$ replaces the contents of the specified index register. The C(AC) are unchanged. A tag of zero results in no-operation.

Indicators. None.
Timing: 1 cycle

Execution. See Figure 39.

SXA - Store Index in Address

Description. The $c(y)_{21-35}$ are replaced by the contents of the specified index register. The $c(y)_{8,1-20}$ are unchanged. With a tag of 0, $c(y)_{21-35}$ are replaced with zeros.

Indicators. None.

Timing: 2 cycles.

Execution. See Figure 39.

SXD — Store Index in Decrement

Description. The $c(y)_{3-17}$ are replaced by the contents of the specified index register. The $c(y)_{8,1,2,18-85}$ are unchanged. With a tag of 0, decrement is replaced with zeros.

Indicators. None.

Timing: 2 cycles.

Execution. See Figure 39.

Logical Operations

Logical instructions operate on a 36-bit word. The sign position is simply another bit position. The exception to this is when the P position is used instead of the sign position. Logical instructions are frequently used in a process called *masking*. This is the process of extracting one or more small parts of a word from the whole word and is called bit processing.

The AND and OR concept is used with logical operations. When two numbers are combined by an AND, they are matched bit-for-bit. If the same position in each word contains a 1, the result is a 1. If in one word the position is 0 and in the other word it is a 1, the result is a 0. If the same position in both words is a 0, the result is a 0. The following is an example of a logical AND operation:

101101011011 101001001101 101001001001 P coulting

101001001001 Resulting AND

An or function (sometimes called "inclusive or") also matches two numbers bit-for-bit. The difference, however, when compared with an AND, is: (1) if the same position in either word contains a 1, the result is a 1; (2) if the same position in both words is a 1, the result is again a 1; (3) only if the same position in both words is a 0, is the resulting position a 0. For example:

011010110101 001100100100

011110110101 Resulting inclusive or

One other function of the logical operations is an exclusive or. In this operation, only those positions which do not match result in a 1. If the same position in each word is a zero or if the same position in each word is a 1, the result is a zero. If the same position in one word is a 1 and in the other a 0, then the result is a 1. For example:

101101100101 001011001101 100110101000 Resulting exclusive or

ORA - OR to Accumulator

Description. Each bit of the $C(Y)_{S,1-35}$ is matched with the corresponding bit of the $C(AC)_{P,1-85}$. $C(Y)_{S}$ is matched with $C(AC)_{P}$.

Indicators. None.

Timing: 2 cycles

Execution. When the corresponding bit of either location Y or the Ac (or both) is a 1, a 1 replaces the contents of that position in the Ac. When the corresponding bits of both location Y and the Ac are 0's, a 0 replaces the contents of that position of the Ac. The c(x) and the S and Q positions of the Ac are unchanged. See Figure 40.

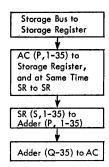

Figure 40. ORA Flow Chart

ORS — OR to Storage

Description. Each bit of the $C(AC)_{P,1-35}$ is matched with the corresponding bit of the $C(Y)_{S,1-35}$, $C(AC)_{P}$ being matched with $C(Y)_{S}$.

Indicators. None.

Timing: 2 cycles

Execution. When the corresponding bit of either the AC or location Y (or both) is a 1, a 1 replaces the contents of that position in location Y. When the corresponding bits of both the AC and location Y are 0's, a 0 replaces the contents of that position in location Y. The C(AC) are unchanged. See Figure 41.

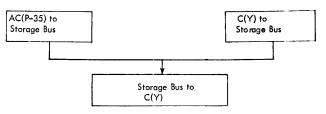

Figure 41, ors Flow Chart

ANA — AND to Accumulator

Description. Each bit of the $C(Y)_{S,1-35}$ is matched with the corresponding bit of the $C(AC)_{P,1-35}$. $C(Y)_8$ is matched with $C(AC)_P$.

Indicators. None.

Timing: 3 cycles

Execution. When the corresponding bits of both location Y and the AC are 1's, a 1 replaces the contents of that position in the AC. When the corresponding bit of either location Y or the AC, or both, is a 0, a 0 replaces the contents of that position in the AC. The S and Q positions of the AC are cleared. The C(Y) are unchanged. See Figure 42.

ANS - AND to Storage

Description. Each bit of the $C(AC)_{P,1-35}$ is matched with the corresponding bit of the $C(Y)_{8,1-35}$, $C(AC)_{P}$ being matched with $C(Y)_{8}$.

Indicators. None.

Timing: 4 cycles

Execution. When the corresponding bits of both the AC and location Y are 1's, a 1 replaces the contents of that position in location Y. When the corresponding bit of either the AC or location Y, or both, is a 0, a 0 replaces the contents of that position in location Y. The C(AC) are unchanged. See Figure 42.

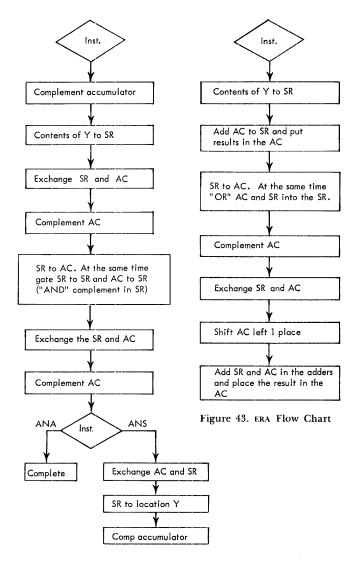

Figure 42. ANA and ANS Flow Chart

ERA — Exclusive OR to Accumulator

Description. Each bit of the $C(Y)_{S,1-35}$ is matched with the corresponding bit of the $C(AC)_{P,1-35}$, $C(Y)_{S}$ being matched with $C(AC)_{P}$.

Indicators. None.

Timing: 3 cycles

Execution. When the corresponding position of the AC matches the position in location Y, a 0 replaces the contents of that position in the AC. When the corresponding position of the AC does not match the position in location Y, a 1 replaces the contents of that position in the AC. Positions S and Q of the AC are cleared. The C(Y) are unchanged. See Figure 43.

THE FOLLOWING logical operations affect the contents of the accumulator only.

COM — Complement Magnitude

Description. All 1's are replaced by 0's and all 0's are replaced by 1's in the $c(AC)_{Q,P,1-35}$. The $c(AC)_{S}$ is unchanged. Address modification may change the instruction itself.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 44.

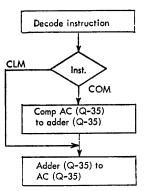

Figure 44. CLM and COM Flow Chart

CLM — Clear Magnitude

Description. The $C(AC)_{Q,P,1-35}$ are cleared. The $C(AC)_{S}$ are unchanged. Address modification by an index register may change the operation itself.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 44.

CHS — Change Sign

Description. If AC sign is plus, it is made negative. If it is negative, it is made plus. Address modification by an index register may change the operation itself. $C(AC)_{Q,P,1-35}$ are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 45.

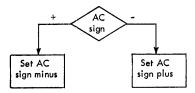

Figure 45. chs Flow Chart

SSP — Set Sign Plus

Description. The sign of the AC is set to plus (0). Address modification by an index register may result in changing the operation itself.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 46.

SSM - Set Sign Minus

Description. The sign of the AC is set to minus (1). Address modification may result in changing the operation itself.

Indicators. None

Timing: 2 cycles

Execution. See Figure 48.

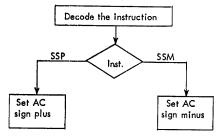

Figure 46. ssm and ssp Flow Chart

Sense Indicator Operations

The following 24 instructions make reference to the 36-bit sense indicator (si) register. The 36 bits of the si may be thought of as switches which may be turned on or off and tested either singly or in groups by the program.

The contents of the si register are manipulated through the use of a *mask*. The mask is a bit pattern comprised of 1's and 0's which may appear in an instruction, the AC, or any storage location. All masks for si operations are used in the same way; that is,

each position in the mask is compared with the corresponding position in the si register. For the positions in the mask which contain a 1, the corresponding position in the si is either modified or tested depending upon the si operation used. For the zero bits in the mask, the corresponding positions of the si are not affected.

Four of the sense indicator operations are concerned with the transmission of full 36-bit words between the st and either the AC or core storage. The remaining 20 operations are used to test or modify the c(st). These 20 operations may be classified by the following five functions:

- 1. Set or Logical OR. These operations replace with a 1, the contents of each si position selected by the mask.
- 2. Reset. These operations replace with a 0 the contents of each si position selected by the mask.
- 3. Invert. These operations replace the contents of each si position selected by the mask with its complement; i.e., 1's are replaced by 0's and 0's are replaced by 1's.
- 4. On Test. These operations examine the contents of each si position selected by the mask. If all examined positions contain a 1, the calculator will either transfer to a location Y or skip the next instruction, depending upon the testing operation used.
- 5. Off Test. These operations examine the contents of each si position selected by the mask. If all examined positions contain a 0, the calculator either transfers to location Y or skips the next instruction, depending upon the testing operation used.

PAI - Place Accumulator in Indicators

Description. The $C(AC)_{P,1-35}$ replace the $C(SI)_{0-35}$. The C(AC) are unchanged.

Indicators. None.

Timing: 1 cycle.

Execution. See Figure 47.

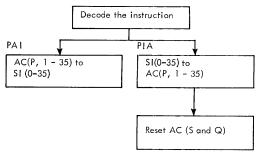

Figure 47. PAI and PIA Flow Chart

PIA - Place Indicators in Accumulator

Description. The $C(SI)_{0-35}$ replace the $C(AC)_{P,1-35}$. Positions S and Q of the AC are cleared. The C(SI) are unchanged.

Indicators. None.

Timing: 1 cycle.

Execution. See Figure 47.

LDI - Load Indicators

Description. The $C(Y)_{S,1-35}$ replace the $C(SI)_{0-35}$. The C(Y) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 48.

STI — Store Indicators

Description. The $C(SI)_{0-35}$ replace the $C(Y)_{S,1-35}$. The C(SI) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 49.

OAI - OR Accumulator to Indicators

Description. Each bit of the $C(AC)_{P,1-35}$ is matched with the corresponding bit of the $C(SI)_{0-35}$. The C(AC) are unchanged. When the corresponding bit of either

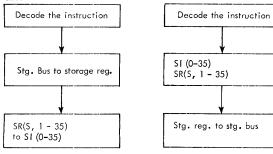

Figure 48. LDI Flow Chart

Figure 49. str Flow Chart

(or both) the AC or SI is a 1, a 1 replaces the contents of that position in the SI. When the corresponding bit of both the AC and SI is a 0, a 0 replaces the contents of that position of the SI.

Indicators. None.

Timing: 1 cycle.

Execution. See Figure 50.

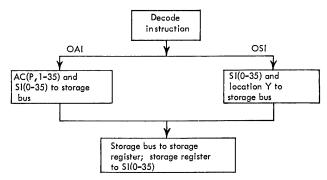

Figure 50. OAI and OSI Flow Chart

OSI — OR Storage to Indicators

Description. Each bit of the $C(Y)_{S,1-35}$ is matched with the corresponding bit of the $C(SI)_{0-35}$. The C(Y) are unchanged. When the corresponding bit of either location Y or SI (or both) is a 1, a 1 replaces the contents of that position of the SI. When the corresponding bit of both Y and SI is a 0, a 0 replaces the contents of that position in the SI.

Indicators. None.

Timing: 2 cycles

Execution. See Figure 50.

SIL - Set Indicators of Left Half

Description. Each bit in positions 18-35 (R) of this instruction is matched with the corresponding bit of the $C(SI)_{0-17}$. The $C(SI)_{18-85}$ and R are unchanged. When the corresponding bit of either (or both) R or the SI is a 1, a 1 replaces the contents of that position in the SI. When the corresponding bit of both the R and the SI is a 0, a 0 replaces the contents of that position in the SI.

Indicators. None.

Timing: 1 cycle.

Execution. See Figure 51.

SIR — Set Indicators of Right Half

Description. Each bit in positions 18-35 (R) of this instruction is matched with the corresponding bit of the $c(sI)_{18-35}$. The $c(sI)_{0-17}$ and R are unchanged. When the corresponding bit of either (or both) R or the si is a 1, a 1 replaces the contents of that position in the si. When the corresponding bit of both the R and si is a 0, a 0 replaces the contents of that position in the si.

Indicators. None.

Timing: 1 cycle.

Execution. See Figure 52.

RIA — Reset Indicators from Accumulator

Description. Each bit of the $C(AC)_{P,1-35}$ resets to 0 the corresponding bit of the $C(SI)_{0-35}$. The C(AC) are unchanged.

Indicators. None.

Timing: 1 cycle.

Execution. When the bit in the AC is a 1, a 0 replaces the contents of that position in the sI. When the bit in the AC is a 0, the contents of that position in the sI are unchanged. This is accomplished by taking the contents of the accumulator, bit for bit, and feeding it into a reset input of the sense register. This input will accept only a "1" pulse which turns that position off (0 condition).

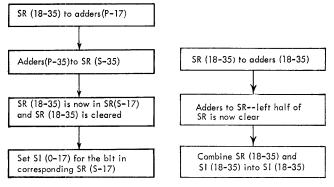

Figure 51. sil Flow Chart

Figure 52. sir Flow Chart

RIS - Reset Indicators from Storage

Description. Each bit of the $C(Y)_{8,1-85}$ resets to 0 the corresponding bit of the $C(SI)_{0-85}$. The C(Y) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. When the bit in location Y is a 1, a 0 replaces the contents of that position in the st. When the bit in location Y is a 0, the contents of that position in the st are unchanged. The operation is identical to that of RIA except that the contents of a storage location, instead of the accumulator, are used to reset the indicators.

RIL — Reset Indicators of Left Half

Description. Each bit in positions 18-35 (R) of this instruction resets to 0 the corresponding bit of the $C(SI)_{0-17}$. The $C(SI)_{18-35}$ and R are unchanged.

Indicators. None.

Timing: 1 cycle.

Execution. When the bit in R is a 1, a 0 replaces the contents of that position in the si. When the bit in R is a 0, the contents of that position in the si are unchanged. The operation is identical to that of RIA except that positions 18-35 of the RIL instruction are used to reset positions 0-17 of the sense indicators.

RIR — Reset Indicators of Right Half

Description. Each bit in positions 18-35 (R) of this instruction resets to 0 the corresponding bit of the $c(si)_{18-35}$. The $c(si)_{0-17}$ and R are unchanged.

Indicators. None.

Timing: 1 cycle.

Execution. When the bit in R is a 1, a 0 replaces the contents of that position in the si. When the bit in R is a 0, the contents of that position in the si are unchanged. The operation is identical to that of RIA except that positions 18-35 of the RIR instruction are used to reset positions 18-35 of the sense indicators.

IIA — Invert Indicators from Accumulator

Description. Each bit of the $c(AC)_{P,1-85}$ is matched with the corresponding bit of the $c(SI)_{0-35}$. When the bit in the AC is a 1, the contents of that position in the SI are complemented. When the bit in the AC is a 0, the contents of that position in the SI are unchanged. The c(AC) are unchanged.

Indicators. None.

Timing: 1 cycle.

Execution. Sense indicator positions may have "binary input." When this input is used, a "1" pulse fed to the position will reverse its status. For example, if the position holds a 0 and a 1 is fed to it, the position will reverse to a 1 status. Likewise, if the position holds a 1 and a 1 is fed to it, it will flip to a zero status. Zeros fed to the binary input do not affect the position. For the IIA instruction, the $C(AC)_{P,1-3\delta}$ are fed to the binary inputs of the SI(0-35).

IIS — Invert Indicators from Storage

Description. Each bit of the $C(Y)_{8,1-35}$ is matched with the corresponding bit in the $C(SI)_{0-35}$. When the bit in the location Y is a 1, the contents of that position in the SI are complemented. When the bit in location Y is a zero, the contents of that position in the SI are unchanged. The C(Y) are unchanged.

Indicators. None.

Timing: 2 cycles

Execution. The same procedure as IIA except that the contents of storage location Y, instead of the contents of the accumulator, are used to reset the sense indicators.

IIL — Invert Indicators of Left Half

Description. Each bit of positions 18-35 (R) of this instruction is matched with the corresponding bit of the $c(si)_{0-17}$. The $c(si)_{18-35}$ and R are unchanged. When the bit in R is a 1, the contents of that position in the si are complemented. If the bit in R is a zero, the contents of that position in the si are unchanged.

Indicators. None.

Timing: I cycle.

Execution. The same as IIA except that 18-35 of this instruction is used in resetting positions 0-17 of the sense indicators.

IIR — Invert Indicators of Right Half

Description. Each bit of positions 18-35 (R) of this instruction is matched with the corresponding bit of the $C(SI)_{18-35}$. The $C(SI)_{0-17}$ and R are unchanged. When the bit in R is a 1, the contents of that position in the sI are complemented. When the bit in R is a zero, the contents of that position in the sI are unchanged.

Indicators. None.

Timing: 1 cycle.

Execution. The same as IIA except that 18-35 of the IIR are used to reset positions 18-35 of the sense indicators.

TIO — Transfer when Indicators On

Description. For each bit in the $c(AC)_{P,1-35}$ that is a 1, the corresponding position of the $c(si)_{0-35}$ is examined. If all the examined positions in the si contain a 1, the computer takes its next instruction from location Y. If any of the examined positions is not a 1, the computer takes the next sequential instruction. The c(AC) and c(si) are unchanged.

Indicators. Trap mode.

Timing: 2 cycles

Execution. See Figure 53.

TIF — Transfer when Indicators Off

Description. For each bit of the $c(AC)_{P,1-85}$ that is a 1, the corresponding position of the $c(si)_{0-35}$ is examined. If all examined positions contain 0's, the computer takes its next instruction from location Y. If any of the examined positions does not contain a 0, the computer takes the next sequential instruction. The c(AC) and c(si) are unchanged.

Indicators. Trap mode.

Timing: 2 cycles

Execution. See Figure 53.

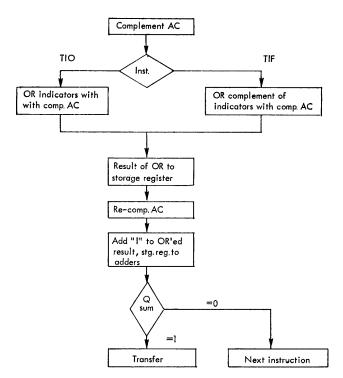

Figure 53. TIO and TIF Flow Chart

ONT - On Test for Indicators

Description. For each bit in the $C(Y)_{8,1-35}$ that is a 1, the corresponding position of the $C(SI)_{0-35}$ is examined. If all the examined positions in the SI contain a 1, the computer skips the next instruction and proceeds from there. If any of the examined positions do not contain 1's, the computer takes the next sequential instruction. The C(Y) and C(SI) are unchanged.

Indicators. None.

Timing: 4 cycles

Execution. See Figure 54.

OFT — Off Test for Indicators

Description. For each bit of the $C(Y)_{S,1-35}$ that is a 1, the corresponding position of the $C(SI)_{0-35}$ is examined. If all the examined positions contain 0's, the computer skips the next instruction and proceeds from there. If any of the examined positions does not contain a 0, the computer takes the next sequential instruction. The C(Y) and C(SI) are unchanged.

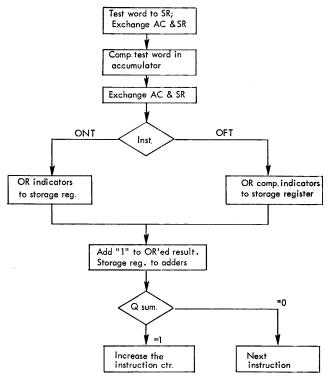

Figure 54. ONT and OFT Flow Chart

Indicators. None.

Timing: 4 cycles

Execution. See Figure 54.

LNT — Left Half Indicators on Test

Description. For each bit in positions 18-35 (R) of this instruction that is a one, the corresponding position of the $C(SI)_{0-17}$ is examined. The C(SI) and R are unchanged. If all the examined positions contain a 1, the computer skips the next instruction and proceeds from there. If any of the examined positions does not contain a 1, the computer takes the next sequential instruction.

Indicators. None.

Timing: 3 cycles

RNT — Right Half Indicators on Test

Description. For each bit in positions 18-35 (R) of this instruction that is a 1, the corresponding posi-

tion of the $c(si)_{18-35}$ is examined. The c(si) and R are unchanged. If all the examined positions contain a 1, the computer skips the next instruction and proceeds from there. If any of the examined positions does not contain a 1, the computer takes the next sequential instruction.

Indicators. None. Timing: 3 cycles

LFT - Left Half Indicators Off Test

Description. For each bit in positions 18-35 (R) of this instruction that is a 1, the corresponding position of the $C(SI)_{0-17}$ is examined. The C(SI) and R are unchanged. If all the examined positions contain a 0, the computer skips the next instruction and proceeds from there. If any of the examined positions does not contain a zero, the computer takes the next sequential instruction.

Indicators. None. Timing: 3 cycles

RFT — Right Half Indicators Off Test

Description. For each bit in positions 18-35 (R) of this instruction that is a one, the corresponding position of $c(si)_{18-35}$ is examined. If all the examined positions contain a zero, the computer skips the next instruction and proceeds from there. If any of the examined positions does not contain a zero, the computer takes the next sequential instruction. The c(si) and R are unchanged.

Indicators. None. Timing: 3 cycles

Convert Instructions

The convert operations enable a program to have very rapid access to information stored in tables in core storage. A single convert instruction can perform a series of table look-up operations by making multiple references to core storage. Three such convert operations are available in the computer.

To illustrate the method of execution of these convert instructions, the following section describes the

CONVERT BY REPLACEMENT FROM THE MQ (CRQ) instruction. The following two definitions will apply throughout this description:

Argument—The known reference factor necessary to find a desired item in a table.

Function—The unknown factor in a table associated with a known reference factor (argument).

The contents of the MQ are interpreted as six 6-bit quantities. Each of these quantities may be considered as a 6-bit binary integer and will be designated as L1, L2,, L6 (Figure 55).

Figure 55. MQ Register-6-Bit Integers

The number, Y1, contained in the address part of the cro instruction is interpreted by the instruction as the address of the first location (origin) of a table in core storage. The format of a typical table is shown in Figure 56. The 6-bit binary integer, L1, is taken as the first argument and the address Y1 + L1 is formed. The instruction then looks up the word located at Y1 + L1. The left-most six bits of this word, positions S, 1-5, are taken as the desired function V1. This 6-bit number, VI, then replaces the number L1 in the MQ. The right-most 15 bits of this word, positions 21-35, are interpreted as an address, Y2, specifying the origin of a second table in core storage. The number L2 is then taken as the second argument and a reference to the second table is made at location Y2 + L2. The contents of Y2 + L2, positions S, 1-5, make up the second function, V2, and replace L2 in the MQ. Positions 21-35 of this word are interpreted as a third address, Y3, the origin of a third table in core storage, and the process continues.

The function V1 replaces L1 in the MQ through a shifting operation. The MQ is shifted left six positions and the bits of L1 are shifted out of position S of the MQ and are lost. The number V1 then replaces the contents of the MQ, positions 30-35 (Figure 57).

Location	Co	ntents
Y1	V0	Y2
•	•	•
•	·	
Y1 + L1	V1	Y2
	•	•
·		
Y1 + N	VM	Y2
	S 5 6	20 21 3

Figure 56. Convert Table

Figure 57. MQ Register-6 Bit Shift

Thus, the CRQ instruction provides for replacement of the contents of the MQ from left to right.

The number of such table references made by a single convert instruction is specified by the count field, positions 10-17, of the instruction. If a count of six is given, six numbers V1, V2,, V6 will occupy the exact MQ positions originally containing the six corresponding arguments L1, L2,, L6. If a count of one was specified for a CRQ instruction, the final contents of the MQ would be as shown in Figure 57. When a count of more than six is specified, the values taken from the tables during the first six references will be used for additional table references. For example, V1 = L7, V2 = L8, and so on.

After the last function, Vn, has been placed in the MQ, the location in core storage from which Vn has been taken contains as its address part a number, Yn. If the tag field of the convert instruction contains a one, the number Yn replaces the contents of index register 1. This provides a convenient method for the program to determine where the last storage table reference has been made or where the next table reference is to be made. (Only index register 1 can be used.)

The convert by replacement from the AC (CVR) instruction is analogous to the CRQ instruction. For this instruction the $C(AC)_{P,1-35}$ rather than the C(MQ) are interpreted as the 6-bit numbers L1, L2,, L6. Also, the six-place shifts which occur during the execution of the instruction are right shifts rather than left shifts. Thus, for the CVR instruction, the replacement takes place right to left, whereas, for the CRQ, the replacement takes place from left to right.

The cAQ instruction interprets the C(MQ) as six 6-bit quantities L1, L2,, L6 and uses these numbers as arguments in the same manner as the CRQ instruction. However, instead of replacing the numbers L1, L2,, L6, the contents of the looked-up words are added into the AC. The address parts of these words are then used as origins for additional look-ups in the usual manner. Addition into the AC is logical, with the S position of the word being added into the P position of the AC. After an argument has been used for a table reference, the C(MQ) are rotated left so that bits leaving position S enter position 35 of the MQ. Thus, if a count of six is specified for a CAQ instruction, the final and original C(MQ) are identical.

CVR — Convert by Replacement from the AC

Description. This instruction treats the C(AC)_{P,1-85} as six 6-bit quantities and replaces the first C of these quantities by values from tables in core storage. Position S of the AC is unchanged. Note: Bit position Q is not cleared and will or with the first function, if present initially.

Indicators. None.

Timing: 2-8 cycles

Execution. The instruction is executed in the following steps:

- 1. The address part (Y) replaces the C(SR)₂₁₋₃₅.
- 2. The count field (C) is placed in the shift register.
- 3. The contents of the shift register are tested. If the register contains zero, step 4a follows. If the register is non-zero, step 4b follows.
- 4a. If position 20 of this instruction contains a 1, the $C(SR)_{21-35}$ replace the contents of index register 1 (XRA), and the computer takes the next sequential instruction. If position 20 contains a 0, the computer proceeds directly to the next sequential instruction.
- 4b. The $C(SR)_{21-35}$ are added to the $C(AC)_{30-35}$ to form an address (X). The C(X) replace the C(SR).
- 5. The $C(AC)_{Q,P,1-35}$ are shifted right six places. Positions vacated are filled with zeros.
- 6. The $C(SR)_{S,1-5}$ replace the $C(AC)_{P,1-5}$. However, if position Q of the AC initially contains a 1, it will be shifted to position 5 of the AC during step 5. This 1 in position 5 of the AC will remain regardless of the contents of position 5 of the SR.
- 7. The contents of the shift register are decreased by one and the computer returns to step 3.

CRQ — Convert by Replacement from the MQ

Description. This instruction treats the C (MQ) as six 6-bit quantities and replaces the first C of these quantities by values from tables in core storage.

Indicators. None.

Timing: 2-8 cycles

Execution. The instruction is executed in the following steps:

- 1. The address part (Y) replaces the $c(s_R)_{21-35}$.
- 2. The count field (C) is placed in the shift register.

- 3. The contents of the shift register are tested. It the register contains 0, step 4a follows. If the register is not 0, step 4b follows.
- 4a. If position 20 of this instruction contains a 1, the $C(SR)_{21-35}$ replace the contents of XRA and the computer proceeds to the next sequential instruction. If position 20 contains a 0, the computer proceeds directly to the next sequential instruction.
- 4b. The $C(SR)_{21-35}$ are added to the $C(MQ)_{S,1-5}$ to form an address (X). The C(X) then replace the C(SR).
- 5. The c (MQ) are shifted left six places. Bits shifted out of position S of the MQ are lost. Positions vacated are filled with zeros.
 - 6. The $C(SR)_{S,1-5}$ replace the $C(MQ)_{30-35}$.
- 7. The contents of the shift register are decreased by one, and the computer returns to step 3.

CAQ - Convert by Addition from the MQ

Description. This instruction treats the C(MQ) as six 6-bit quantities. The first C of these quantities are used in making references to tables in core storage. Words selected by the references are added to the $C(AC)_{Q,P,1-35}$. Position S of the AC is unchanged. Note: Care should be taken that the binary sum of the quantities added from 21-35 does not carry into position 19 of the AC.

Indicators. None.

Timing: 2-8 cycles

Execution. The instruction is executed in the following steps:

- 1. The address part (Y) replaces the $C(SR)_{21-35}$.
- 2. The count field (C) is placed in the shift register.
- 3. The contents of the shift register are tested. If the register contains 0, step 4a follows. If the register is not 0, step 4b follows.
- 4a. If position 20 of this instruction contains a 1, the $C(SR)_{21-35}$ replace the contents of XRA, and the computer proceeds to the next sequential instruction. If position 20 contains a 0, the computer proceeds directly to the next sequential instruction.
- 4b. The $C(SR)_{21-35}$ are added to the $C(MQ)_{S,1-5}$ to form an address (X). The C(X) then replace the C(SR).
- 5. The c(MQ) are rotated six positions to the left. Bits leaving position S of the MQ enter position 35.
- 6. The $C(SR)_{S,1-35}$ are added to the $C(AC)_{Q,P,1-35}$ and the sum replaces the $C(AC)_{Q,P,1-35}$. The sign position of the SR is added into position P of the AC, and the sign

of the AC is disregarded. Note: Even though AC overflow is possible, the overflow indicator is not affected by this instruction.

7. The contents of the shift register are reduced by one and the computer returns to step 3.

The reader is referred to the CONVERT programming examples contained in the programming section of this manual for possible uses of these instructions.

Input-Output Operations

As has been previously stated, the address part of an instruction may refer either to a location in core storage, the length of shift, or may be interpreted as a part of the operation code itself.

The identifying number for the various input-out-put units appears in the address part of the instruction. For tapes, card machines and printers the address part specifies both the particular 1-0 unit and the data channel to which it is attached. Channels A through H are specified by the numbers 1 through 10, respectively, appearing as the first two digits of an octal five-digit address. The last three digits specify the 1-0 unit. If the 1-0 unit is a tape, the mode of operation, either binary or BCD, is also specified by the address.

The addresses of the input-output devices are shown below:

DEVICE	CHANNEL	BCD ADDRESS	BINARY ADDRESS
Tapes	A	1201-1212	1221-1232
	В	2201-2212	2221-2232
	C	3201-3212	3221-3232
	D	4201-4212	4221-4232
	\mathbf{E}	5201-5212	5221-5232
	F	6201-6212	6221-6232
	G	7201-7212	7221-7232
	H	10201-10212	10221-10232
Card Reader	A	1321	
	В	2321	
	C	3321	
	D	4321	
	\mathbf{E}	5321	
	\mathbf{F}	6321	
	G	7321	
	H	10321	
Card Punch	Α	1341	
	В	2341	
	C	3341	
	D	4341	
	${f E}$	5341	
	F	6341	
	G	7341	
	Н	10341	
		DECIMAL	BINARY
Printer	Α	1361	1362
	В	2361	2362
	С	3361	3362
	D	4361	4362
	E	5361	5362
	F	6361	6362
	G	7361	7362
	H	10361	10362

In the following instruction description, only the operation code will be shown. The address part will appear in the normal code of Y. All input-output instructions may be trapped using the compatibility feature.

Since it is possible to create magnetic tapes of mixed density, precautions should be taken so that all read tape instructions are executed when the tape unit is set to the density in which the tape was recorded.

RDS — Read Select

Description. This instruction causes the computer to prepare to read information, from the 1-0 device specified by Y, into core storage. If Y specifies a tape, printer, or card reader, Y also specifies the channel to which the device is attached.

Any attempt to read in one density a tape that was recorded in the other density will result in both detected and undetected errors. When RDS is used to skip tape, proper tape density must also be used.

Indicators. Simulate, end of file. (See device being used.)

Timing: 2 cycles

Execution. When a channel is designated, a RESET AND LOAD CHANNEL instruction must be given within the specified time following the RDS, or the I-O device will be logically disconnected from the computer and one record will be passed. (See each device for timings.) No other select instruction should be inserted between the RDS and its associated RCH. When an RDS specifies channel operation, only positions 27-35 of the address part of the instruction are subject to effective address modification.

WRS - Write Select

Description. This instruction causes the computer to prepare to write information from storage to the 1-0 device specified by Y. If Y specifies a tape, printer or card punch, Y also specifies the channel to which the device is attached.

Indicators. Simulate, end of tape. (See device being used.)

Timing: 2 cycles

Execution. When a channel is designated, a RESET AND LOAD CHANNEL instruction must be given within specified time following the WRS, or the 1-0 device will be logically disconnected from the computer and, it the WRS specified a tape, a blank section of tape will be written. No other select instruction should be inserted between the WRS and its associated RCH. If the end of tape reflective spot is encountered during the execution of a WRS, the end-of-tape indicator in the proper channel will be turned on. When a WRS specifies an 1-0 device attached to a channel, only positions 27-35 of the address part of the instruction are subject to effective address modification.

BSR — Backspace Record

Description. This instruction causes the tape designated by Y to move backward until recorded information is reached and then to continue this backward motion over information until an end-of-record gap or load point is encountered.

The tape unit must be in the proper density mode (the same as the tape being backspaced) before the BSR is executed, or tape positioning errors will occur.

Indicators. Beginning of tape and simulate.

Timing: 2 cycles

Execution. If the tape designated by Y is positioned at its load point, a BSR is interpreted as a no-operation and the beginning-of-tape indicator in the proper channel is turned on. If load point is encountered before information is encountered, the BOT indicator is turned on. Only positions 27-35 of the address part of this instruction are subject to effective address modification.

BSF - Backspace File

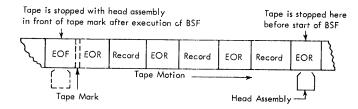

Description. This instruction causes the tape designated by Y to move backward until recorded information is reached and then to continue this backward motion over information and end-of-record gaps until an end-of-file record or the load point is encountered.

The tape unit must be in the proper density mode (the same as the tape being backspaced) before the BSF is executed, or tape positioning errors will occur.

Indicators. Beginning of tape, simulate.

Timing: 2 cycles

Execution. If a BSF is given to a tape positioned at its load point, the BSF is interpreted as a no-operation and the beginning-of-tape indicator in the proper channel is turned on. If load point is encountered before an end-of-file record, the beginning-of-tape indicator is turned on. Only positions 27-35 of the address part of this instruction are subject to effective address modification.

WEF - Write End-of-File

Description. This instruction causes the tape designated by Y to write an end-of-file gap followed by a tape mark (and its check character) on the tape.

Indicators. End of tape, simulate.

Timing: 2 cycles

Execution. If an end of tape reflective spot is passed over during the execution of a WEF, the end-of-tape indicator in the proper channel is turned on. Only positions 27-35 of the address part of this instruction are subject to effective address modification.

REW — Rewind

Description. This instruction causes the tape designated by Y to rewind its tape to the load point position.

Indicators. Simulate.

Timing: 2 cycles

Execution. If the tape is positioned at its load point at the time the REW is interpreted, the instruction is treated as a no-operation. Only positions 27-35 of the address part of this instruction are subject to effective address modification. If a second REW is given to a tape unit that is executing a REW or RUN, the second REW is treated as a no-operation (NOP).

RUN — Rewind and Unload

Description. The tape unit designated by the address portion of this instruction will be rewound and then put into an automatic unload status.

Indicators. None. Timing: 2 cycles

Execution. This instruction will be executed in the same manner as a rewind instruction except that it will never be treated as a no-operation if the tape is positioned at load point when execution occurs. After the rewind, a normal unload operation will occur as if the operator had depressed the unload key. Only positions 27-35 of this instruction are subject to modification by index register action. With a tape at load point, this instruction will cause an unload operation only. If a second Run is given to a tape unit that is executing a Run or Rew, the second Run is treated as a no-operation (NOP).

SDN - Set Density

Description. The address portion of this instruction will determine which density mode is being used for a given tape operation.

Indicators. None.

Timing. 2 cycles.

Execution. The address portion of this instruction will include the data channel being used, tape unit number, and the density mode as follows:

CHANNEL	HIGH DENSITY	LOW DENSITY
A	1221- 1232	1201- 1212
В	2221- 2232	2201 - 2212
C	3221- 3232	3201 - 3212
D	4221- 4232	4201 - 4212
\mathbf{E}	5221- 5232	5201- 5212
F	6221- 6232	6201- 6212
G	7221- 7232	7201- 7212
H	10221-10232	10201-10212

Care must be taken in using this instruction because of the possibility of changing the density mode in the middle of a tape. When power is first applied to the 7094 system, all tape units will automatically be placed in high density status.

RDCA — Reset Data Channel A

Description: This instruction resets all registers and indicators in the designated data channel. All transmission is terminated and tape or other selected units are immediately disconnected. If the instruction

is executed while a tape is in motion, the tape is stopped *immediately* regardless of the position of the tape head with regard to the inter-record gap. Any instructions which have been stacked will be lost and status indicators previously set by an enable instruction will be turned off.

Timing: 2 cycles.

Execution: All registers, indicators and control elements that are turned off by the reset key on the data channel console are turned off by this instruction. Since the primary purpose of this instruction is to clear a channel after it has been "hung up" by selecting a unit that is not ready, no attempt is made to synchronize its operation with 1-0 units. Use of the instruction for other purposes may result in unpredictable operation. Address modification may cause the operation code (positions 27-35 only) to be changed. Instruction codes and mnemonics for each channel are:

RDCB	+07602352
RDCC	+07603352
RDCD	$+0760 \dots 3352$
RDCE	+07605352
RDCF	+07606352
RDCG	+07607352
RDCH	+07607352
KDUII	1 0700, 10004

The following program is an example of using the RDC to determine ready status of tape units attached to channel A. The program stores a bit pattern in location STAT such that a 1-bit signifies the tape unit is ready (position 35 corresponds to unit 1, 34 to unit 2, etc.).

LOCATION	INSTRUCTION	ADDRESS	COMMENTS
	TCOA	*	
	STZ	STAT	
	\mathbf{AXT}	10, 1	
	CAL	ONE	
READY	BSRA	11, 1	
	CRQ	0, ,15	Delay is approximately 30 microseconds
	TCOA	*+2	
	ORS	STAT	Ready
	ALS	1	Not Ready
	RDCA		•
	CRQ	0, ,15	Delay approximately 30 microseconds
	TIX	READY, 1, 1	
ONE	HTR	1	
STAT	OCT	0	

In this program, the RDC instruction serves two purposes:

- 1. If the tape is not ready, the channel is cleared so that the next 1-0 instruction will be accepted (in the CPU).
- 2. If the tape is ready, execution of the RDC will effectively stop the backspace operation before it gets started so that the tape does not move from its original position.

Input-Output Transmission Operations

Instructions that either send commands to a data cnannel or store information from data channel registers are classified as input-output transmission operations. These instructions are described in groups of eight. All eight instructions within a group are identical in function and differ only in that each refers specifically to one of the eight possible data channels. The instructions will be described for data channel A.

SCHA — Store Channel A (7607 Data Channel)

Description. This instruction replaces the c(y) with the contents of the channel A address, location, and operation registers. If channel A is not attached to the computer when the scha is given, the c(y) are cleared by the scha.

Indicators. None.

Timing: 2 cycles

Execution. The $C(Y)_{21-35}$ are replaced by the C(AR), the $C(Y)_{3-17}$ are replaced by the C(LR), and the $C(Y)_{8,1,2,19}$ are replaced by the contents of the operation register. An scha instruction may be executed at any time, regardless of whether or not the specified channel is in operation. If the channel is in operation and the channel registers are in the process of being changed, the execution of the scha will be delayed until the change has been completed. Note that the C(AR) will be one greater than the storage location of the last word involved in data transmission and that the C(LR) are one greater than the storage location from which the current command was taken. A channel relinquishes priority between the time the last word is transmitted by an 10CP or 10SP command and the arrival of a subsequent channel command. Therefore, an sch may store an address which is one greater than the address of the last word transmitted by the IOCP or IOSP commands.

INSTRUCTION	CODE	N/	AME	
SCHB	-0640	Store	Channel	В
SCHC	+0641	Store	Channel	С
SCHD	-0641	Store	Channel	\mathbf{D}
SCHE	+0642	Store	Channel	E
SCHF	-0642	Store	Channel	\mathbf{F}
SCHG	+0643	Store	Channel	G
SCHH	-0643	Store	Channel	H

RCHA — Reset and Load Channel A (7607)

Description. If channel A has been selected by either an RDs or WRS, the $C(Y)_{8,1,2,19}$ replace the channel operation register, $C(Y)_{3-17}$ replace the C(WR) and the

 $C(Y)_{21-85}$ replace the C(AR). In addition, the number Y plus one replaces the C(LR).

Indicators. 1-0 Check.

Timing: 3 cycles

Execution. If channel A is not selected when the RCHA is given, the RCHA executes normally but the 1-0 indicator is turned on (If the command loaded by the RCHA specifies indirect addressing, it will not occur). For each RDS or WRS, the corresponding RCHA must be given if any transmission between storage and the selected 1-0 device is to take place. If a second RCHA is given at a later time, the order is executed immediately. No other select instruction should be inserted between the RCH and its associated WRS or RDS. See "Programmed Interruption of a Data Channel" for further details regarding this type of operation.

INSTRUCTION	CODE	NAME
RCHB	-0540	Reset and Load Channel B
RCHC	+0541	Reset and Load Channel C
RCHD	-0541	Reset and Load Channel D
RCHE	+0542	Reset and Load Channel E
RCHF	-0542	Reset and Load Channel F
RCHG	+0543	Reset and Load Channel G
RCHH	-0543	Reset and Load Channel H

LCHA — Load Channel A (7607)

Description. If the data channel has been selected, the computer delays until an IOCT, IORT, OR IOST command is processed for channel A or the channel leaves operation. After an IOCT, IORT, OR IOST command has been executed by the channel A, the LCHA is executed as shown below.

Indicators. 1-0 check.

Timing: 3 cycles,

Execution. The $c(Y)_{S,1,2,19}$ replace the contents of channel A operation register. $c(Y)_{3-17}$ replace the c(WR), the $c(Y)_{21-35}$ replace the c(AR), and the number Y plus one replaces the c(LR). If an LCHA is issued and either (1) the channel is not selected, or (2) channel A is selected but an IOCT, IORT, or IOST command is not executed before the channel disconnects, the 1-0 check indicator is turned on and the LCHA is treated as a no-operation.

LCHF	-0546	Load Channel F
LCHG	+0547	Load Channel G
LCHH	-0547	Load Channel H

Data Channel Commands

The eight types of data channel commands are described in much the same manner as other computer instructions. The following steps list command conditions:

- 1. The letter Y in the address part (21-35) of a command is used to denote a core storage location.
- 2. The letter C in the decrement part (3-17) of a command is used to denote a word count amount.
- 3. The numerical operation code is shown by an octal digit in the prefix part (S, 1 and 2). The digit may be visually converted to its binary equivalent for reference to the bit pattern actually used.
- 4. Indirect addressing of data channel commands is possible on the 7094 system. Position 18 of the command contains the flag bit. Thus, with a command having an address part (Y) and a one in position 18, the address part of location Y replaces the address part of the command before it is executed. With a zero word count, indirect addressing does not occur on 100p or 10sp commands. Indirect addressing will occur only on read or write operations.
- 5. Separate commands have not been formulated to handle bit position 19. Instead, a fifth character (N—denoting non-transmit) is appended to the mnemonic codes used for positions S, 1, and 2. This type of command is used for read operations only.
- 6. Seven of the eight commands deal with data transmission. The codes for these commands all contain the letters "1-0".
- 7. The eighth command is a transfer in channel command.
- 8. The word disconnected means that the units involved are separated logically rather than physically. When a disconnect is signalled, it may be delayed depending on the operation being performed. For example:
- a. Write Tape. Disconnect will not occur until the end of record gap is written. This permits a programmed ETT or TRC test to be valid if given after the channel leaves operation (disconnects).
- b. Read Tape. Disconnect will not occur until tape control circuits and tape units have accepted the read instruction. This assures that any read select instruction will move tape before the disconnect occurs even if an immediate disconnect is programmed. Disconnect will not occur between the last word of the record and the interrogation of the longitudinal redundancy check character (LRC). This assures that with a channel programmed to read an entire record, a TRC test, given after the

channel leaves operation, will have tested the LRC character.

Recognition of an end of file, while reading tape or cards, causes a disconnect regardless of the command being used. The tape unit does not leave operation until the LRC character has been checked and the end of record reached. An IORP, IORT, IOSP, or IOST command will not recognize a logical end of record on an end of file.

c. Card Machines. Unless a disconnect is programmed immediately following a transmission or end of record time, the disconnect will generally be delayed until the next transmission or end of record time. For example, if the channel is loaded with an IOCD command (with zero word count) ten milliseconds after end of record time, an extra machine cycle will occur. The disconnect then occurs at the 9-left transmission time of this extra cycle.

IN EXECUTION descriptions of the 1-0 commands, tape is assumed to be the 1-0 device. However, mechanical motion on the tape (from record to record) may be compared to card equipment (from card to card or line to line) on the printer. The descriptions may then be applied to 1-0 devices other than tape.

IOCD — Input-Output under Count Control and Disconnect

Description. C words are transmitted between an 1-0 device and core storage beginning with location Y. The data transmission is under control of the count (C) field only.

Indicators. See 1-0 device being used.

Timing: See 1-0 device being used.

Execution

Read Operation. If the word count has been reduced to zero before a record gap is reached, the channel leaves operation and tape motion will continue until a record gap is reached. No transmission will occur during this time. If a record gap is encountered when the word count is not zero, the gap is ignored and reading continues from the next record. An ioco command with a 0 word count, loaded at the end of record will disconnect the channel.

Write Operation. When C words have been written on tape, a record gap is written. If this command is given at the beginning of a record and C is initially zero, approximately 3% inches of blank tape will be written before the record gap is written. The channel is then disconnected.

IOCP — Input-Output under Count Control and Proceed

Description. C words are transmitted between an I-O device and core storage location Y. The data transmission is under control of the count field only. When C is reduced to zero, or is initially zero, the next sequential command is brought into the data channel and executed.

Indicators. See 1-0 device being used.

Timing. See 1-0 device being used.

Execution

Read Operation. C words are read from tape and stored in consecutive storage locations beginning with location Y. When the word count has been reduced to zero, the channel takes its next command in sequence and executes it.

If the word count is reduced to zero by the last word of a record and the next command is an iorp, iorp, ior, or ior, the present end of record will be recognized. Unlike the iorp, the iorp command need not proceed within 11 cycles in order to recognize the present end of record.

Write Operation. C words from storage beginning with location Y are written on tape. When the specified words have been written, the channel proceeds to the next sequential command. An end of record is not written on tape when the word count is reduced to zero.

In printing or the punching of cards, if the word count is reduced to zero on the 12-row right transmission point, and the next command is an IORP OF IORT, the end of the present machine cycle (record) will be recognized.

IORP — Input-Output of a Record and Proceed

Description. See "Execution."

Indicators. See 1-0 device being used.

Timing: See 1-0 device being used.

Execution

Read Operation. Words are transmitted from tape and stored in consecutive storage locations, beginning with location Y, until either an end of record is encountered or the word count has been reduced to zero. If the word count is reduced to zero (or is initially zero) before an end of record is reached, the rest of the words in that record are skipped without

transmission to storage. When the record gap is reached, the channel takes the next sequential command.

Write Operation. When C words have been written, a record gap is written and the channel proceeds to the next sequential command.

IOCT — Input-Output under Count Control and Transfer

Description. C words are transmitted between an 1-0 device and storage beginning with location Y. The data transmission is under control of the count field only. When C is reduced to zero, the next command is taken from a core location specified by the load channel instruction in the main program or disconnects (and traps if the channel is enabled) if no load channel instruction is waiting. If this command is loaded by an RCH or LCH instruction and C is initially zero, the channel is immediately disconnected unless restricted by the operation.

Indicators. Command Trap.

Timing: See 1-0 device being used.

Execution

Read Operation. Execution of the command is under control of the count field only and end of record gaps are ignored. If the word count is reduced to zero by the last word of a record and the next command is an iorp, iorp, iort, or iort, the present end of record will be recognized. Unlike the iort command, the lch instruction need not load the channel within 11 cycles in order to recognize the present end of record.

Write Operation. An end of record will not be written after C words have been written if the LCH instruction results in bringing into the channel a new word count.

In printing or the punching of cards, if the word count is reduced to zero on the 12-row right transmission point and the next command is an IORP or IORT, the end of the present machine cycle (record) will be recognized.

IORT — Input-Output of a Record and Transfer

Description. See "Execution."

Indicators. Command trap.

Timing: See 1-0 device being used.

Execution

Read Operation. Words are transmitted from tape and stored in consecutive storage locations, beginning with location Y, until either an end record is encountered or the word count has been reduced to zero. If the word count is reduced to zero (or is initially zero) before an end of record is reached, the rest of the words in that record are skipped without transmission to storage. When the record gap is reached, the next command is taken from a core location specified by the LCH instruction in the main program or disconnects (and traps if the channel is enabled) if no LCH is waiting.

Write Operation. When C words have been written, a record gap is written and the channel takes its next command from a core location specified by the LCH instruction in the main program or disconnects (and traps if the channel is enabled) if no LCH instruction is waiting.

IOSP — Input-Output until Signal, then Proceed

Description. See "Execution."

Indicators. See 1-0 device being used.

Timing: See 1-0 device being used.

Execution

Read Operation. Words are read into consecutive storage locations beginning with location Y until either the contents of the word counter are reduced to zero or an end of record is reached. When either event occurs, the channel proceeds immediately to the next sequential command and executes it.

With a tape read operation and an IOSP or IOST command whose word count is reduced to zero by the last word in the record and whose next command is an IORP, IORT, IOSP, or IOST, this next command will normally enter the channel in time to recognize the present end of record. This next command transmits no data and is effectively skipped. If this next command cannot enter the channel within 11 machine cycles, the IORP, IORT, IOSP, or IOST command will not recognize the present end of record gap, but will process the following record. To determine if this sequence can be safely programmed, three cycles should be allowed if the CPU is processing a TCO instruction (five cycles if other instructions are being processed) plus one cycle for each channel in operation, plus one cycle for each channel programmed with proceed commands, plus one cycle for each channel which may process a TCH at this time, plus one cycle for each channel which may have indirect addressing at this time. If the total exceeds 11 cycles, the sequence described must not be used.

Write Operation. C words are written on tape beginning with storage location Y. When the specified words have been written, the channel proceeds to the next sequential command. An end of record is not written on tape when the word count is reduced to zero. Note that this is identical to the operation of the IOCP.

In printing or the punching of cards, if the word count is reduced to zero on the 12-row right transmission point and the next command is an IORP or IORT, the end of the present machine cycle (record) will be recognized.

IOST - Input-Output until Signal then Transfer

Description. See "Execution."

Indicators. See 1-0 device being used.

Timing: See 1-0 device being used.

Execution

Read Operation. Words are read into consecutive storage locations beginning with location Y until either the contents of the word counter are reduced to zero or an end of record is reached. When either event occurs, the channel takes its next command from a core location specified by the LCH instruction in the main program or disconnects (and traps if the channel is enabled) if no LCH instruction is waiting.

With a tape read operation and an 10sT command whose word count is reduced to zero by the last word in the record and whose next command is an IORP, IORT, IOSP, or IOST, this next command will normally enter the channel in time to recognize the present end of record. This next command transmits no data and is effectively skipped. If this next command cannot enter the channel within 11 cycles, the IORP, IORT, IOSP, or lost command will not recognize the present end of record gap but will process the following record. To determine if this sequence can be safely programmed, two cycles should be allowed for the LCH instruction plus one cycle for each channel in operation, plus one cycle for each channel programmed with proceed commands, plus one cycle for each channel using indirect addressing. If the total exceeds 11 cycles, this sequence must not be used.

Write Operation. C words are written on tape from storage beginning with location Y. When C words have been written, the channel takes its next command from a core location specified by the LCH instruction

in the main program or disconnects (and traps if the channel is enabled) if no LCH instruction is waiting to be executed.

In printing or the punching of cards, if the word count is reduced to zero on the 12-row right transmission point and the next command is an IORP or IORT, the end of the present machine cycle (record) will be recognized.

TCH - Transfer in Channel

Description. This command is the transfer command for all data channels.

Indicators. None.

Timing: 2 cycles

Execution. When a TCH command is executed, the data channel proceeds immediately to its next command which is taken from location Y. The location register is set to Y+1. The command located at Y is then loaded into the data channel.

Program Examples

The following examples illustrate the use of data channel commands to read and write tape. The programs, aside from the instructions and command codes, are shown in the octal number system.

Figure 58 shows a program which may be used to read and skip tape records. The first instruction (500) selects the proper channel and tape. The second one loads the first command (1000) into the channel. The command execution proceeds as follows:

LOCATION	INS	TRUCTION	COMMENTS
00500	RDS	01201	Select tape 1, channel A
00501	RCHA	01000	Load first command
		•	•
		•	•
] .			
01000	IOCP	00006 0 03000	Read first six words
01001	IOCPN	00005 2 00000	Skip next five words
01002	IORP	77777 0 03006	Read remaining words in record
01003	IOCD	00000 0 00000	Disconnect

Figure 58. Read and Skip Tape Program

1000—IOCP 00006 0 03000. This command reads the first six words from tape and places them into core locations starting with 3000.

1001 — IOCPN 00005 2 00000. This command reads, but does not transmit, the next five words, in effect skipping them.

1002 – IORP 77777 0 03006. The next command reads the remaining words in the record into locations starting with 3006. When the record gap is

sensed, the next command (10CD) will disconnect the channel and the tape unit, thus ending the channel program.

Figure 59 shows a program that could be used to write all of core storage on a tape and delay at location 502 until all but the last word has been written.

The first two instructions select the channel and tape unit to be used and load the first channel command. The central processing unit then senses the load channel instruction (LCHF) and the main program will wait until the next-to-last word has been written before loading the second channel command which will write location 77777 and disconnect both the channel and the tape unit.

LOCATION	INSTRUCTION		COMMENTS
00500	WRS	06202	Select tape 2, channel F
00501	RCHF	01000	Load first command
00502	LCHF	01001	Wait until last word, then load
•		•	channel F
	•		•
01000 01001	IOCT IOCD	77777 0 00000 00001 0 77777	Write locations 00000–77776 Write location 77777 and then disconnect

Figure 59. Write Tape Program

Channel Trap Operations

ENB — Enable from Y (7607 Operation)

Description. When this instruction is executed, the contents of location Y determine which signals may cause a trapping operation. Execution of each enable instruction cancels the effect of previous enable instructions. All channels may be disabled (traps will not occur) by executing an enable instruction whose operand contains all zeros.

Indicators: Trap Control.

Timing: 2 cycles

Execution. Trapping signals are controlled as follows:

SIGNAL DUE TO	CHANNEL	EFFECTIVE II A "1" IN POSITION
Channel command or EOF	Α	0035
Channel command or EOF	В	0034
Channel command or EOF	C	0033
Channel command or EOF	D	0032
Channel command or EOF	E	0031
Channel command or EOF	F	0030
Channel command or EOF	G	0029
Channel command or EOF	H	0028
Tape check	A	0017
Tape check	В	0016
Tape check	C	0015
Tape check	D	0014
Tape check	E	0013
Tape check	F	0012
Tape check	Ğ	0011
Tape check	H	0010

Execution of a trap will inhibit all further traps until a new enable instruction is executed or a restorechannel-trap instruction is executed. Depression of the reset, clear key, or execution of an RDC instruction, will also disable all channels.

RCT — Restore Channel Traps

Description. This instruction will allow traps to occur as specified by the previous enable instruction. It cancels the inhibiting effect of an executed trap.

Indicators. Trap Control.

Timing: 2 cycles

Execution. Since the address part of this instruction is a part of the operation code, modification by an index register may change the operation itself.

System Compatibility Operations

ESNT — Enter Storage Nullification and Transfer

Description. This instruction turns on a half-storage mode indicator, which serves as a protective device for a program being run while using the compatibility feature of the computer.

Indicators. Simulate, trap mode.

Timing: 1 cycle

Execution. With the half-storage mode indicator on, the following events occur: (1) the upper half of storage is made unavailable for reference by a 704 program, (2) index register capacity is halved, and (3) program control is transferred to location Y. The indicator may be reset by depressing the reset, clear, or any of the load keys, execution of any 1-0 trap (except data channel trap), or execution of an LSNM instruction.

LSNM — Leave Storage Nullification Mode

Description. Execution of this instruction returns the computer system to its normal operating capacity

by turning the half-storage mode indicator off. If the computer is in its normal operating mode and an LSNM instruction is executed, the instruction will be treated as a no-operation.

Indicators. Simulate.

Timing: 2 cycles

Execution. Since the address part of this instruction is a part of the operation part, modification by an index register may change the operation itself.

ESTM — Enter Select Trap Mode

Description. This instruction turns on the select trap mode indicator, and, while in this mode, 1-0 select and sense instructions are not executed but are trapped. It should be used before entry into a 704 program, so that a 704 instruction will be trapped rather than result in indefinite delays.

Indicators. Simulate.

Timing: 2 cycles

Execution. Instructions that will be trapped include: WEF, BSF, BSR, REW, RDS, WRS, I-O SENSE, RTT, EOT, redundancy and BOT. The location plus one of the trapped instruction is stored in core storage location 40,000. Program control is transferred to location 40,001. Trapping also turns off the half-storage, select trap, and copy trap indicators. The indicators may also be turned off by: depression of reset, clear, or load keys, or execution of any I-O trap (except a data channel trap). Since the address part of this instruction is a part of the operation code, modification by an index register may change the operation itself.

ECTM - Enter Copy Trap Mode

Description. This instruction turns on the copy trap mode indicator. With the indicator on, CPY, CAD, and LDA instructions (709 instructions) are trapped instead of being executed. With the indicator off, these instructions can cause unpredictable operations.

Indicators. Simulate.

Timing: 2 cycles

Execution. The location plus one of the trapped instruction is stored in core location 40,000 and program control is transferred to location 40,002. The execution of this instruction will also turn off the half-storage, select trap, and the copy trap mode indicators. The copy trap mode indicator may also be turned off by: depression of the clear, reset, or load keys, or the execution of any 1-0 trap (except a data channel trap). Since the address of this instruction is a part of the operation code, modification by an index register may change the operation itself.

EFTM — Enter Floating Trap Mode

Description. This instruction turns on the indicator for floating-point trap mode. When in this mode, floating-point overflow and/or underflow will cause a trapping operation.

Indicators. MQ overflow.

Timing: 2 cycles

Execution. This mode is the normal operating mode. Floating-point overflow-underflow have the operating characteristics of the standard computer (store location plus one in address 0000 and then transfer to 0010). Since the address part of this instruction is a part of the operation code, modification by an index register may change the operation itself.

LFTM — Leave Floating Trap Mode

Description. This instruction turns off the floating trap mode indicator, giving the computer floating-point overflow characteristics of the standard 704 (turns on the AC or MQ overflow indicators only).

Indicators. MQ overflow.

Timing: 2 cycles

Execution. Depression of the reset, clear, or load keys will return the computer to its normal operating mode (floating trap mode) by turning the floating trap mode indicator on. Since the address of this instruction is a part of the operation code, modification by an index register may change the operation itself.

Commands and Instructions for the IBM 7909 Data Channel

The following instructions and commands are used with the 7909 Data Channel and its attached adapter and input-output devices. Execution timing is not included, because it depends on command organization in core storage and the status of the addressed data channel.

IBM 7909 Data Channel Instructions

RSCA — Reset and Start Channel A

Description. On execution of this instruction, the channel is selected and reset and takes its next command from location Y. The instruction is interlocked against channel activity; if the instruction is executed while the channel is busy, its execution is delayed until the channel is in wait status.

Indicators. None.

Execution. If the selected channel is in wait status, the $c(Y)_{s,1-3,19}$ replace the channel operation register, $c(Y)_{3-17}$ replace the word counter, and $c(Y)_{21-35}$ replace the contents of the address counter. In addition, the number Y+1 replaces the contents of the command counter. If the channel is not in wait status, the execution of the CPU program is delayed until the channel executes either a WTR or TWT command.

Instruction codes for other channels are:

INSTRUCTION	CODE	NAME
RSCB	-0540	Reset and Start Channel B
RSCC	+0541	Reset and Start Channel C
RSCD	0541	Reset and Start Channel D
RSCE	+0542	Reset and Start Channel E
RSCF	0542	Reset and Start Channel F
RSCG	+0543	Reset and Start Channel G
RSCH	0543	Reset and Start Channel H

STCA - Start Channel A

Description. Execution of this instruction is delayed if the channel is not in wait status. If in wait status, the channel is started and takes its next command from the address part of the wait command.

Indicators. None.

Execution. If the channel is in wait status, the command counter is reset and replaced with the

contents of the address counter. The channel then executes the command at the location specified by the command counter and increments the command counter by one (adds one to the command counter contents).

Instruction codes for other channels are:

INSTRUCTION	CODE	NAME
STCB	-0544	Start Channel B
STCC	+0545	Start Channel C
STCD	-0545	Start Channel D
STCE	+0546	Start Channel E
STCF	-0546	Start Channel F
STCG	+0547	Start Channel G
STCH	-0547	Start Channel H

SCHA - Store Channel A

	+0640	F	Т		Υ
S, 1		11 12-13 14	17 18-20	21	35

Description. Execution of this instruction causes the specified channel to be selected and that channel's command counter contents to be placed in positions 21-35 of location Y. The channel's address counter contents are placed in positions 3-17 of location Y. Positions S, 1, 2, 18, 19, and 20 of location Y are reserved and their contents cannot be predicted.

Indicators. None.

Execution. The $c(y)_{21-35}$ are replaced by the contents of the command counter and $c(y)_{3-17}$ are replaced by the contents of the address counter. The scha instruction may be executed at any time, regardless of whether the specified channel is in operation. The command counter may contain the location of the current command or of the next command to be executed.

Instruction codes for other channels are:

INSTRUCTION	CODE	NAME
SCHB	-0640	Store Channel B
SCHC	+0641	Store Channel C
SCHD	-0641	Store Channel D
SCHE	+0642	Store Channel E
SCHF	-0642	Store Channel F
SCHG	+0643	Store Channel G
SCHH	-0643	Store Channel H

ENB - Enable from Y (7909)

Description. When this instruction is executed, the contents of location Y determine which signals may cause a trap operation. Execution of each enable instruction cancels the effect of previous enable instructions. The channel may be disabled (traps will not occur) by executing an enable instruction whose operand contains a zero in the proper position.

Indicators: Trap Control.

Execution. Trapping signals are controlled as follows:

SIGNAL DUE TO	CHANNEL	EFFECTIVE IF A 1 IN POSITION
TWT Command	A	0035
TWT Command	В	0034
TWT Command	\mathbf{C}	0033
TWT Command	D	0032
TWT Command	${f E}$	0031
TWT Command	\mathbf{F}	0030
TWT Command	\mathbf{G}	0029
TWT Command	Н	0028

Execution of a trap inhibits all further traps until a new enable instruction is executed or a restore channel traps instruction is executed. Depression of the reset or clear key or execution of an RIC instruction also disables the data channel.

RICA - Reset Channel A

Description. This instruction, when executed, causes all conditions in the channel to be reset. The instruction is not interlocked against channel activity. If data transmission is taking place when an RIC occurs, validity of the data already transmitted cannot be guaranteed.

Indicators. None.

Execution. The RIC resets all conditions in the channel to normal initial status and also sends a reset pulse to the adapter. Modification of the address of the RIC may change the operation itself.

Instruction codes for the other channels are:

INSTRUCTION	CODE	NAME
RICB	+0760-2350	Reset Channel B
RICC	+0760 - 3350	Reset Channel C
RICD	+0760-4350	Reset Channel D
RICE	+0760-5350	Reset Channel E
RICF	+0760-6350	Reset Channel F
RICG	+0760-7350	Reset Channel G
RICH	+0760-10350	Reset Channel H

SCDA — Store Channel Diagnostic, Channel A

+0644	F	Т	Υ
S. 1	11 12 13 14	17 18 20 21	35

Description. Execution of this instruction causes the specified channel to be selected and the specified channel's diagnostic indication to be stored in bit positions S-16 of location Y. Positions 17-35 are reserved, and their contents cannot be predicted. Indicators and corresponding positions are:

CHANNEL INDICATOR	Y POSITION
Control Counter (1-6)	S-5
I-O Check	6
Sequence Check	7
Unusual End	8
Attention 1	9
Attention 2	10
Adapter Check	11
Prepare to Read	12
Prepare to Write	13
Read Status	14
Write Status	15
Interrupt	16
Reserved	17-35

Indicators. None.

Execution. The c(Y) S-16 are replaced by the contents of the channel indicators. The SCD instruction may be executed at any time, whether the specified channel is in operation or not. Codes and mnemonics for other channels are:

CODE	NAME
-0644	Store Channel Diagnostic, Channel B
+0645	Store Channel Diagnostic, Channel C
-0645	Store Channel Diagnostic, Channel D
+0646	Store Channel Diagnostic, Channel E
-0646	Store Channel Diagnostic, Channel F
+0647	Store Channel Diagnostic, Channel G
-0647	Store Channel Diagnostic, Channel H
	$-0644 \\ +0645 \\ -0645 \\ +0646 \\ -0646 \\ +0647$

Other 7909-CPU Instructions

Operation of the following CPU instructions is compatible with operation on the 7607 Data Channel: IOT, RCT, TCNX, and TCOX.

The BTT and ETT instructions always result in a skip, because neither indicator is turned on by the 7909 Data Channel. For the same reason, the TRC and TEF instructions never result in a transfer.

An RDC addressed to a 7909 Data Channel has no effect. Data select instructions (RDS and WRS) or non-data select instructions (BSR, BSF, WEF, REW, RUN, and SDN) addressed to a 7909 cause the 7094 CPU to hang up but have no effect on the 7909 Data Channel.

IBM 7909 Data Channel Commands

CTL — Control

Description. If position N is a zero, information contained in c(y) is sent to the control unit, starting with the high-order character, and continues until an end signal is received from the control unit. If more than one word location is necessary to transmit all data required by the channel, the next word is taken from Y+1, etc. This process continues until an end signal is received. The next command is then taken

from the storage location following the CTL command. If N is a one, the channel proceeds to the next sequential command.

Execution. If N is a zero, the contents of the address counter are replaced by Y, and the data register contents are replaced by the c(y). When the first data request is received from the control unit, the data register contents enter the assembly register, and the c(y+1) replace the contents of the data register. The contents of the assembly register are sent to the control unit character by character, starting with the high-order character under control of the unit. Successive words are sent until an end signal is received from the control unit.

CTLR — Control and Read

Description. If N is a zero, this command causes the channel to transmit control information, as with the CTL, and also prepares the channel for a read operation. When an end signal is received from the control unit, the channel proceeds to the next sequential command (which must be a copy or a TCH to a copy if data transmission is expected). If position N is a one, this command prepares the channel to read and proceeds to the next sequential command. When a copy command is encountered, the channel is placed in read status, and data are transmitted to core storage under control of the copy command.

Execution. Execution is the same as with the CTL except that the prepare to read indicator in the 7909 data channel is turned on.

CTLW - Control and Write

Description. If N is a zero, this command causes the channel to transmit control information, as with the CTL, and also to prepare the channel for a write operation. When an end signal is received from the control unit, the channel proceeds to the next sequential command (which must be a copy or a TCH to a copy if data transmission is expected). If N is a one, this command prepares the channel to write and proceeds to the next sequential command. When a copy command is encountered, the channel is placed in write status, and data are transmitted from core storage to the control unit under control of the copy command.

Execution. Execution is the same as with CTL except that the prepare to write indicator in the 7909 is turned on.

SNS - Sense

Description. Execution of this command places the channel in sense status and then proceeds to the next sequential command (which must be a copy or a TCH to a copy if sense data transmission is expected). When a copy command is encountered, sense information is sent to core storage under control of the copy command.

Execution. Execution of the sns turns on a sense indicator in the 7909, which causes the adapter to transmit sense data. The channel then proceeds to the next sequential command. A copy (CPYP or CPYD) command is required to provide word count and address information to be used in storing the sense data. If the sns is not immediately followed by a copy command or a TCH to a copy command, a sequence check occurs. If the assembly register is filled before a copy command is encountered, an 1-0 check results.

A maximum of two sense data words are available from the adapter. Both words can be stored, or it is possible to store only the first word by using a CPYD with a word count of 1. The meaning of each sense data-bit, as placed in core storage from the 7631 File Control is:

SENSE	RIT	BCD		
WORD		BITS	STATUS INDICATION	COMMENT
1	1	Α	Reserved	
î	3	4	Program Check	Summary Byte
i	4	2	Data Check	Summary Byte
î	$\hat{5}$	1		Summary Byte
i	7	A	Exceptional Condition	Summary Byte
î	9	4	Invalid Sequence Invalid Code	Program Check
i	10	2	Format Check	Program Check
î	11	1	No Record Found	Program Check
i	13	À	Invalid Address	Program Check
i	15	4		Program Check
1	16		Response Check	Data Check
1	17	2 1	Data Compare Check	Data Check
1		1	Parity or Check Char Code Check	Data Check
1	19	Α	Access Inoperative	Exceptional Condition
1	21	4	Access Module Not Ready	Exceptional Condition
1	22	2	Disk/Drum Storage	Exceptional Condition
			Circuit Check	1
1	23	1	File Control Circuit Check	Exceptional Condition
1	25	A	Reserved	Data Mode
1	27	4	Six-Bit Mode	Data Mode
1	28	2	Reserved	Data Mode
1	29	1	Reserved	Data Mode
1	31	Α	Module 0	Attention
1	33	4	Module 1 Disk Only	Attention
1	34	2	Module 2	Attention
1	35	1	Module 3 Disk Only	Attention
2	1	Α	Module 4	Attention
2	3	4	Module 5 Disk Only	Attention
2	4	2	Module 6	Attention
2	5	1	Module 7 Disk Only	Attention

Additional details about sense data from the 7640 include:

Attention

OPERATOR REQUIRED

4 Drive 9

This bit is set when operator intervention is required to proceed, as in a failure to execute an instruction or an order because:

- 1. Selected Hypertape drive is not ready.
- 2. Selected drive is not loaded.
- 3. Selected drive is file-protected and an attempt to write is made.
 - 4. The operation was not initiated.

PROGRAM CHECK

This bit is set when the failure to execute an instruction or an order is due to the status of the Hypertape drive and Hypertape control that are under control of the stored program, such as:

- 1. Invalid operation code.
- 2. Selected drive is busy.

- 3. Selected drive is at BOT and a read backward is attempted.
- 4. Selected drive is at EOT and any order requiring forward tape motion is attempted.

DATA CHECK

This bit is set when an error has occurred in the transmission of data during a read, write, or control operation, as the result of any of the following error conditions:

- 1. Correction occurred.
- 2. Channel parity check.
- 3. Code check.
- 4. Envelope check. This indicator turns on when: in reading, an uncorrectable error is sensed; in writing, the failure to write a bit or bits is sensed.
- 5. Overrun. This indicator turns on whenever the computer fails to send or receive a character from the control within the allotted time.
- 6. Excessive Skew Check. This indicator turns on whenever a bit or bits of a read character fail to fall within the time allocated for that character.
- 7. Track Start Check. This indicator turns on because of circuit failure in a bit track.

EXCEPTIONAL CONDITION

This bit is set when an exceptional condition occurs during the execution of a read or write operation. Exceptional condition does not indicate an error condition. The exceptional conditions are:

- 1. Tape mark is sensed when reading.
- 2. Write operation is in progress and end warning area is sensed.

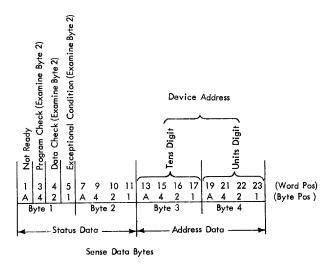

ATTENTION

Ten bits of sense data are used to indicate attention for ten Hypertape drive addresses. These bits are set whenever the corresponding drive signals attention, that is, whenever the drive is placed in ready status or one of the following operations is completed:

> Rewind Unload Cartridge File Protect Rewind and Unload Change Cartridge Change Cartridge and Rewind

The status data bits also indicate the address of the last selected drive of that channel.

Only one word of sense data is available from the 1414-6. The first six positions of the word location in which the sense data are placed (S, 1-5) are called the "Summary Byte." The second six positions (6-11) contain the "Detail Byte." The third and fourth bytes (12-23) contain device addressing information. Positions 24-35 of the location are not used. The bytes are:

The A bit of byte 1 denotes a not-ready condition and is the only bit in byte 1 that can be a 1-bit at the same time that another bit in byte 1 is a 1-bit. Bit positions 4, 2, and 1 are mutually exclusive. Byte 2 conveys different information not only for the different devices being used but also for the different positions of byte 1 that may contain a 1-bit. These conditions and effects are:

CPYD — Copy and Disconnect

Description. This command, when decoded by a channel not prepared to read or write, causes a sequence check and, thus, a channel interrupt. If the channel is prepared to read or write, this command causes C words to be transmitted between the channel and core storage, starting with location Y. Data transmission continues until C is reduced to zero or an END signal is received by the channel. In either case, the channel read or write select is reset. If, while a CPYD is being executed, an END signal is received before the count is reduced to zero, the channel read or write select is reset, and the channel obtains a new command from the next sequential location.

If the next command is other than a copy, the channel executes that command. If the next command is a copy, the channel interrupts on a program sequence check.

If the count for the CPYD goes to zero before the END signal is received, the channel initiates a disconnect but does not get the next sequential command until an END or UNUSUAL END signal is obtained. In general, when operating under CPYD control, the channel does not obtain the next sequential com-

Sun	nmary Position		Detail	Position				
		7	9	10	11			
(1)	NOT READY	The not ready condition denotes: device is not attached, power is off, unit is out of tape or has broken tape, local telegraph station is not ready, or the 1414 buffer being asked for is not on-line.						
(3)	PROGRAM CHECK	Sense without attention, control, or unusual end.	Read command following control to write.	Write command following control to read.	Read or write command without prior control command			
(4)	DATA CHECK			Parity check of the two byte address sent to the 1414-6.	Parity check or 1414 machine check on data transfer to or from the processor.			
(5)	EXCEPTIONAL CONDITION 1009 Read		Buffer being filled.	Buffer overrun trans- mission error between buffer and remote 1009.	End of message.			
	1009 Write		Buffer being emptied.	Transmission error be- tween buffer and re- mote 1009.	End of message acknowledged.			
	1011 Read		Buffer being filled.	Parity error in tape when control panel wired to drop the char- acter or substitute another character; error between 1011 and buffer.				
	1014 Read		Buffer being filled or no request.	Error during buffer fill- ing, or message exceeds 78 characters.				
	1014 Write		Buffer being emptied.	Transmission between 1014 and buffer.				
	Telegraph Read		Buffer being filled (or no input available).	Buffer overrun (buffer not emptying in time). Transmission error be- tween buffer and remote station.				
	Telegraph Write		Buffer being emptied.	Parity or translate error to the line, or transmis- sion error between local and remote stations.				

Interpretation of Sense Data

mand until either an END (or UNUSUAL END signaling an error) occurs. In the event of an UNUSUAL END signal, an interrupt occurs.

Execution: Read or Sense Operation. Y replaces the contents of the address counter. If the channel is in prepare to read status, this condition is reset and the control unit is signaled to begin transmission to core storage. If the read or sense indicator is on from a previous SNS or CPYP, data transmission is continued under control of the CPYD. When the assembly register is full, it is emptied into the data register and access to core storage is requested.

As each word is placed in core storage, the address counter is increased by one and the word counter is decreased by one. If the word count is reduced to zero before an END signal is received, a disconnect is initiated, and the channel obtains its next command when the END signal is received. If a word or partial word has been received, it is stored. If an END signal is received before the word count is reduced to zero, the last word transmitted is stored and the channel gets the next sequential command.

Execution: Write Operation. Y replaces the contents of the address counter. If the channel is in prepare to write status, this condition is reset and the write indicator is turned on. The c(y) are placed in the data register. When the first data request is received from the control unit, data register contents are placed in the assembly register and the c(y+1) replace the contents of the data register.

If the write indicator is on from a previous CPYP command, data transmission is resumed under control of the CPYD. As each word is transmitted to the control unit, one is added to the address counter and the word counter is reduced by one. Disconnect procedures are the same as for a read or sense operation. A CPYD with a word count of zero causes a disconnect without further data transmission.

CPYP — Copy and Proceed

Description. This command, when decoded by a channel not prepared to read or write, causes a sequence check and channel interrupt. If the channel is prepared to read or write, this command causes C words to be transmitted between the channel and core storage, starting with location Y. END signals from the control unit are serviced, the channel does not disconnect and data transmission continues until C is reduced to zero. The channel then does not dis-

connect but obtains the next sequential command. If this command is a TCH, TDC, or a copy, operation is normal and data transmission is resumed. If the next command does not satisfy these conditions, the channel disconnects and interrupts on a sequence error. If an UNUSUAL END occurs, the channel interrupts.

During a read operation, if an end signal is received during a CPYP command, the word or partial word assembled is stored and the control unit is signaled to proceed. During a write operation, if an end signal is received during a CPYP command, the control unit is signaled to proceed. Data transmission is resumed with the next sequential character. If, during writing, the total word count of all CPYP commands is equal to or one greater than the length of the record, there is a possibility that the terminating CPYP command will be skipped, although the control unit will have been logically disconnected.

Execution. End signals from the control unit are serviced during a CPYP command. Following the end signal, however, the 7909 signals the control unit to proceed (write, read, or sense). Unusual end conditions cause a channel interrupt. A CPYP command may be followed by a CPYP, CPYD, or TCH or TDC to another copy command.

Use of the CPYP in 7631 operation should be carefully controlled due to the fixed record length characteristics of the devices attached to the 7631. A normal end should never occur during 7320/1301 operations using a CPYP command. If word counts are not properly controlled (that is, the total word counts of all CPYP commands in a write or read sequence are greater than the record length), or if the word count is equal to the record length and a CPYP or CPYD with a word count follows, data will be destroyed.

Consider a single record operation on disk or drum where the word count of the record is 100:

CTLW	DVSR	Verify single record
CPYP	A,,150	Write 150 words
CPYD	B., 10	Write 10 words

When 100 words have been written, the 7631 sends an END signal. The 7909 signals write again, and the remaining 60 words are dumped on top of the first 100. The remaining 40 (of the original 100) are replaced with zeros and no errors are indicated. This condition is possible on all operations except write format. If an attempt is made to exceed the capacity of a format track, a format check results.

It is generally desirable to follow with a write check operation all write operations using CPYP. This assures error detection if a data wrap-around occurs.

A routine that may be used to write and write check is:

LOCATION	OPERATION	ADDRESS	COMMENT				
	LCC	1					
WR	CTLW	DVSR	Verify single record				
	CPYP	A,,150	Write 150 words				
	CPYD	B, , 10	Write 10 words				
	TDC	*+2	Go to write check if control counter not zero				
WC	WTR	*	End of write, write check				
	CTLW	DWRC	Prepare to write check				
	TCH	WR+1	-				

TCH - Transfer in Channel (7909)

Description. This command is the transfer command for all channels. When a TCH command is executed, command sequence control is transferred to location Y.

Execution. When a TCH command is executed, the data channel transfers to location Y. The command at location Y is loaded into the data channel and the command counter is increased to Y+1.

LAR — Load Assembly Register

Description. Execution of this command causes the contents of the assembly register to be replaced by the C(Y). The C(Y) remain unchanged. After execution, the channel proceeds to the next sequential command.

Execution. The contents of Y are sent through the storage bus switches and the data register to replace the contents of the assembly register.

SAR — Store Assembly Register

Description. Execution of the SAR causes the c(x) to be replaced by the contents of the assembly register. Contents of the assembly register remain unchanged. After execution, the channel proceeds to the next sequential command.

Execution. The assembly register contents are stored

in location Y, as specified by the address counter, in the same manner as for a read operation.

XMT - Transmit

Description. This command causes the C words immediately following the location of the xmt command to be transmitted to C locations starting at location Y. When the C field is reduced to zero and the Cth word has been transmitted, the channel obtains its next command from the location of the xmt command, plus C, plus one. If the initial count field is zero, the xmt command is skipped and the channel proceeds to the next sequential command.

Execution. The command counter is increased by one and the first word is obtained from this location and brought to the data register. The command counter is then increased by one again. The data register contents are stored in location Y. The address counter is increased by one and the word counter is reduced by one. The second word is entered into the data register from the storage location specified by the command counter. This operation proceeds until the word count is reduced to zero. The channel then takes its next command from the location of the XMT command plus C, plus one. The contents of the assembly register remain unchanged. The XMT command may be used to move blocks of data, commands, or entire subroutines from one area of core storage to another area.

LCC - Load Control Counter

Description. This command causes the contents of the channel control counter to be replaced by the six low-order positions of the count field of the LCC command. The channel then proceeds to the next sequential command. If the LCC is indirectly addressed, the contents of the control counter are replaced by the six low-order bits contained in the location specified by positions 21-35 of the LCC command.

Execution. The control counter is reset. The contents of positions 12-17 of the address counter are placed in positions 1-6 of the control counter. The

channel then proceeds to the next command as specified by the command counter.

TDC — Transfer and Decrement Counter

Description. On execution of this command, the contents of the six-bit channel control counter are examined. If the contents are not zero, the counter is reduced by one and control is transferred to location Y. If the counter contents are zero, the channel proceeds to the next sequential command, leaving the counter contents unchanged.

Execution. If the control counter contains a count of zero, the channel proceeds to the next command as specified by the command counter. If the control counter is not zero, it is decreased by one. The command counter is reset and replaced by the contents of the address counter. The channel then takes the next command from location Y.

ICC - Insert Control Counter

Description. When the count field (C) of the ICC is 1-6, this command causes the C field to specify one of the six characters in the assembly register to be replaced by the contents of the control counter. The remaining five characters are not affected. If C is zero, the fifth and sixth characters of the assembly register are replaced by the contents of the sms status indicators. In either case, the channel proceeds to the next sequential command after execution of the ICC. An ICC with a C field of seven functions as a no operation. The contents of the assembly register remain unchanged.

Execution. Word counter positions 3, 4, and 5 are decoded to specify a character of the assembly register. The selected character is reset and replaced by the control counter if the C field is one through six or by the sms status indicators if the C field is zero.

TCM — Transfer on Condition Met

Description. When C is 1 through 6, this command causes C to specify one of the six characters in the assembly register for comparison against the contents of the mask (M). Comparison is achieved in one of two ways, depending on whether bit position 11 of

this command contains a 1 or a 0. If bit position 11 contains a 0, comparison is achieved when the specified character and the mask character are identical, bit for bit. If bit position 11 contains a 1, comparison is achieved only when, for each bit in the mask that is a 1, the corresponding bit position of the specified character is also a 1. If the comparison is achieved, the channel executes a transfer to location Y. If the comparison is not achieved, the channel proceeds to the next sequential command. If C is 0, the channel check condition register is compared against M in either of the two ways described. Transfer conditions resulting from the comparison are as previously stated. When indirect addressing is used, control is transferred to the indirectly addressed location when the condition is met. If C is equal to seven, the results depend on mask contents. If all bits in positions 12-17 of the TCM are 0, the channel executes a transfer to location Y. Otherwise, the channel proceeds to the next sequential command.

Execution. Word counter contents (position 3, 4, and 5) are decoded to find the count. Assembly register contents are divided into six characters with the first character in positions S, 1-5 and the last character in positions 30-35. If the count field is a value one through six, one of the characters from the assembly register (specified by C) is compared with the M field of the TCM. If C is zero, the six-position check condition register is compared with M. If C is seven, a six-bit character of all zeros is compared with M. If a bit-for-bit comparison is achieved, the channel transfers control to location Y. The command counter is reset and replaced with the contents of the address counter. If a comparison is not achieved, the channel proceeds to the next sequential command. The contents of the assembly register and the check condition register remain unchanged.

SMS — Set Mode and Select

Description. Execution of this command causes the contents of positions 29-35 of this command to set or reset specific status indicators as follows:

BIT	FUNCTION
29	Enable non-concurrence interrup
30*	Read Backward
31*	BCD Mode
32	Inhibit Unusual End Signals
33	Inhibit Attention 1 Signals
34*	Inhibit Attention 2 Signals
35*	Select 2 (1 is selected when reset)

*Optional Features

Bits 34 and 35 apply to the data channel switch feature described in "Optional Features."

In all cases, the presence of the bit causes the status indicator to be set and the function to be enabled; absence of the bit resets the status indicator and disables the function. Machine and power-on resets also reset the indicators. With indirect addressing, the sms command status indicators are set or reset with bits 29-35 of the location specified by bits 21-35 of the indirectly addressed command. After execution of the sms, the channel proceeds to the next sequential command.

WTR - Wait and Transfer

Description. When this command is decoded, the channel stops operation and may be thought of as waiting. The channel command counter contains the location of the WTR command. When the channel is told to start, it takes its next command from the location specified by Y of the WTR command. If an interrupt occurs while the channel is in wait status, return from the interrupt program by means of a LIP command puts the channel in wait status.

Execution. Execution of this command forces the channel to wait. The channel may be restarted by either an RSC or STC command or by an interrupt. The command counter is not changed, and the address counter contains Y. If the WTR is indirectly addressed, the address counter contains the contents of the address portion of location Y.

TWT - Trap and Wait

Description. Upon decoding a TWT command, the channel suspends operation until either a reset and start or start channel instruction is executed by the CPU, depending on conditions described below. If the channel is enabled for control word traps, the channel causes the CPU to trap to a fixed location. Particulars concerning this trap are described in "Data Channel Trap."

If the channel is enabled and encounters a TWT command, start channel instructions are ignored until the trap is executed or a reset and start channel instruction is executed. If the channel is not enabled, either a reset and start or start channel instruction resets the trap and causes the channel to resume operation.

Channel interrupt signals are remembered but not executed until the channel brings in a command other than TWT. (An RSC resets these stored interrupt signals.) After the channel has stopped operation as

a result of a TWT, the channel command counter contains the location of that command.

Assume that B is the location where the instruction counter contents are stored when a trap occurs on this particular channel and that CPU control is transferred to B+1. SUB is the entry point for the subroutine that the channel requests the CPU to execute.

COMMAND	ADDRESS	COMMENT
XMT		Moves the following TRA to location $B+1$.
TRA TWT	SUB Y	Transfers control to CPU at location B+1.

Execution. When the TWT is decoded, the wait indicator is turned on, the channel trap demand is initiated, and the channel waits. The command counter is not changed and the address counter contains Y. If the TWT is indirectly addressed, the address counter contains the contents of the address portion of location Y.

LIP - Leave Interrupt Program

Description. This command causes the channel to transfer control to the location contained in the address part of the channel's fixed "interrupt-to" location. The channel command counter is set to the value in the address portion of this fixed location. Execution of the LIP also cancels the inhibiting effect of a previous interrupt.

Execution. The interrupt and check condition indicators are reset and the contents of the address portion of the fixed interrupt-to location are entered in the command counter. The contents of the location specified by the command counter are loaded into the operation register, word counter, and address counter. The command counter is stepped to the location of the next command.

LIPT — Leave Interrupt Program and Transfer

Description. Execution of the LIPT command cancels the inhibiting effect of a previous interrupt and transfers channel control to location Y. Use of the LIPT permits returning from the interrupt subroutine to a program location other than the interrupt address.

Execution. When an LIPT command is executed, the interrupt and check condition indicators are reset and the channel proceeds to location Y for its next command. The command located at Y is loaded into the channel and the command counter is increased to Y+1.

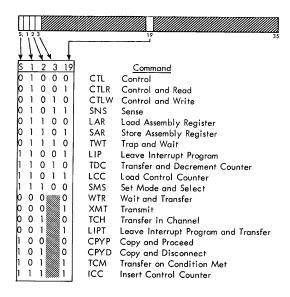

PROGRAMMING EXAMPLE OF LIPT COMMAND

	INSTRUCTION		
LOCATION	OR COMMAND	ADDRESS	COMMENT
100	XMT	RSTRT,,1	Store return address in
101	PZE	102	indirect address restart location.
102	CTLR	DVTN	Read 30 words using
103	CPYP	BEGIN,,10	track with no ad-
104	CPYD	END,,20	dresses.

RSTRT is a location used to store restart addresses. The XMT command stores PZE 102 at location RSTRT. Assume that an 1-0 check occurs during the CPYP command. The channel initiates a disconnect and interrupts. The command counter contains 104, the location of the next command. If the error routine decides to try again, an LIP command cannot be conveniently used, because the channel leaves the interrupt routine and transfers to location 104. A sequence check would occur followed by another interrupt.

If the interrupt routine is ended with an indirectly addressed LIPT command (LIPT RSTRT,4), rather than a LIP, the channel returns to the CTLR command and retries the failing section of the program.

Optional Features

IBM 7909 Data Channel Switch Optional Feature

The IBM 7909 Data Channel Switch permits simultaneous attachment of one or two input-output control units to one 7909 Data Channel. One IBM 7631 File Control and one IBM 1414-6 Input-Output Synchronizer may be attached to one data channel as shown in the flow chart:

When the 7909 is equipped with the channel switch, data transmission occurs between the 7909 and one of the control units. Attention signals, however, are monitored from each control unit simultaneously. The 7909 is then able to select the control unit and determine priority of attention requests by means of its own stored program.

UNUSUAL END and I-O check signals apply only to that control unit currently selected. Indicators are included to record attention signals from the non-selected control unit and to denote which control unit is currently selected. Attention interrupts occur on signal from either or both of the control units and are subject to the same limitations (described earlier) as without this feature.

IBM 7909 Data Channel BCD Translation Optional Feature

This feature provides automatic BCD translation for information transmitted between the input-output adapter and the 7909 Data Channel. After execution of an sms command (with a 1-bit in position 31) data transfers between the 7909 and the adapter are translated as shown in the table that follows. Control and sense data are not translated. An sms command with a 0-bit in position 31 returns data transfer mode to binary.

This feature allows the IBM 7094 system to share data with other systems. Translation of data is shown in the following table with the characters divided into their bit configurations; each character is shown as it appears in core storage and on disk or tape storage:

	C	Ore	Store	age		İ	Ta	pe o	Dis	k Sto	orage	•]
В	Α	8	4	2	1	T	В	Α	8	4	2	1
0	0	0	0	0	0	T	0	0	1	0	1	0
0	0	1	0	1	0		0	1	0	0	0	0
0	0	(otl	ner)				0	0	(no	cho	inge))
0	1	(an	У				1	1	(no	cho	inge))
1	0	(an	y)				1	0	(nc	cho	inge)
1	1	0	0	0	0		0	0	0	0	0	0
1	Ī	(otl	ner)				0	1	(nc	cho	inge))
						1						

With the translation feature enabled, binary data may be written in BCD format and recovered by reading in the BCD mode. No indication occurs when data written in one mode are read in the other mode.

Home addresses and record addresses may be written using BCD format. This automatically provides the BCD format required in all address areas. Note, however, that subsequent attempts to verify an address written in BCD format will fail unless the adapter orders are modified to conform to disk storage BCD codes. Information sent to the adapter during a control operation is not translated whether in BCD mode or not. This is a restriction only where portions of the address are alphabetic characters. Numeric addresses must always be expressed in BCD format.

IBM 7909 Data Channel Read Backward Character Assembly and Storage Optional Feature

This feature provides automatic backward reading in the 7909 for use with the read backward capabilities of IBM 7340-1 Hypertape.

An sms command with a 1-bit in position 30 enables backward reading. When the read backward indicator in the channel is on, characters received from the control unit are assembled in reverse order. The assembled words are then stored in descending core storage locations. The first word is stored in the location specified by the CPYP or CPYD command. Successive words are stored in this location minus 1, minus 2, etc. Write, control, and sense operations are not affected by the feature.

An sms command with a 0-bit in position 30 returns character and word assembly to normal status.

PROGRAM EXAMPLE

LOCATION	OPERATION	ADDRESS	COMMENT
\mathbf{A}	SMS	40	Set backward mode
	CTLR	В	Prepare to read
	CPYD	C, , 10	Read 10 words
	WTR	*	End of read
В	OCT	120701120100	
\mathbf{C}	BES	10	

Word 1 is assembled backward and then stored at location C; word 2 is stored at location C-1; word 3, at C-2, and so on.

The 7909 Data Channel is capable of interrupting its stored program independently of the main computer and of other data channels. This operation is separate and distinct from a data channel trap (which interrupts the CPU) and represents another significant departure from 7607 Data Channel operation. On recognition of an interrupt condition, the 7909 channel stores the contents of the command and address counters in a fixed location and then executes the command located in another fixed location. This process is termed interrupt. When a 7909 is attached to a 7094 system, the channel tape check indicator for that channel (located on the IBM 7151-2 Console Control Unit) is used to display the status of the 7909 interrupt indicator.

If the 7909 channel is to be diverted from normal command execution sequence, the command in the fixed location must be one that will change the contents of the command counter (TCH, LIPT, or successful TDC or TCM). If this command is other than a successful transfer, the channel executes it and resumes operation at the location specified by adding one (1) to the value of the command counter as stored at the fixed interrupt locations. If the command at the second fixed location is a WTR or TWT, the channel suspends operation as described under "7909 Commands," but the command counter contains the same location that was stored when the interrupt occurred. If the interrupt occured during the WTR command, the stored command counter is the location of the WTR command. If the interrupt occured during any other command, the stored command counter is the location plus one of that command. The channel interrupt locations are assigned as follows:

	STORE COMMAND	OBTAIN NEXT
CHANNEL	COUNTER AT	COMMAND FROM
A	00042	00043
В	00044	00045
\mathbf{C}	00046	00047
D	00050	00051
E	00052	00053
F	00054	00055
G	00056	00057
H	00060	00061

When the 7909 interrupts, the command and address counters are automatically stored in the assigned fixed core storage location. The address counter is stored in positions 3-17 and the command counter in positions 21-35 of this same location. If the contents of the fixed store location for the address counter are modified by the program, positions S, 1, 2, 18, 19. and 20 should be zeros. Otherwise, a program hangup may occur when the 7909 executes an LIP command.

Interrupt conditions are stored in a six-position register in the data channel and may be examined with the TCM command. Any combination of interrupt conditions causes an interrupt; however, once interrupted, the channel is placed in interrupt mode and further attempts to set the interrupt condition or to interrupt are inhibited. The channel remains in interrupt mode until an LIP or LIPT command is executed by the channel or an RIC instruction is executed by the CPU. If the channel is in interrupt mode and an RSC instruction is executed by the CPU before the channel executes an LIP or LIPT command, the interrupt condition register is reset but the channel remains in interrupt mode. An LIP or LIPT command or an RIC instruction is the only program means available to cause the channel to exit from the interrupt mode and become receptive to further interrupt conditions.

Interrupts are also inhibited if channel trap is in process on that channel. This inhibiting persists until either an RSC or STC instruction (depending on whether the channel was enabled) is executed by the CPU (see "TWT Description").

Interrupt Conditions

Interrupt indications are stored in a six-position register in the data channel. The contents of this register may be examined by the TCM command. The positions of the register and the conditions they reflect are:

POSITION	CONDITION
1	Input-Output Check
2	Sequence Check
3	Unusual End
4	Attention I
5	Attention 2
6	Input-Output Adapter Check

Input-Output Check

This condition occurs when the channel fails to obtain a storage reference cycle in time to satisfy demands of the attached 1-0 device. The condition is also monitored in the CPU and reflected by the I-O check light. The condition of the light may be tested by the CPU, using the 10T instruction. 10T instruction execution

turns the I-O check light off in the CPU but will not affect the 7909 I-O check indicator. The 7909 I-O check indicator is turned off when an LIP or LIPT command is executed or when the CPU executes an RSC or RIC instruction.

The channel 1-0 check indicator's being on indicates one of the following conditions:

- 1. During a write or control operation, the channel data register has not been loaded with a word from core storage by the time its contents are to be sent to the control unit.
- 2. During a read or sense operation, the channel data register has not been stored by the time new data are completely assembled in the assembly register.

When an I-O channel check occurs, the control unit is disconnected and an interrupt occurs when the END signal is received from the control unit. The command counter contains the location plus one of the present command. The address counter contains the location plus one or two of the last word transmitted if the operation was a write or control, or the location plus one of the last word transmitted if the operation was a read or sense.

If an I-O check occurs while the channel is in interrupt mode, the I-O check is not recognized and is not saved.

Sequence Check

A sequence check indicates an invalid sequence of channel commands. Improper command sequences occurring while the channel is in interrupt mode may cause the 7909 to hang up. If a sequence check occurs during data transmission, the control unit is logically disconnected and the interrupt occurs when the end signal is received. In general, data transmission (read, write, or sense operations) may be started by one of the following sequences:

- 1. A CTLR followed by a CPYP or CPYD.
- 2. A CTLW followed by a CPYP or CPYD.
- 3. A sns followed by a CPYP or CPYD.

If transmission has been started with a CPYP, it must be ended with a CPYD. Between the first CPYP and the CPYD, transfers are possible but only four commands (CPYP, TCH, LIPT, OT TDC) are permitted.

The following conditions cause a sequence check and a channel interrupt:

- 1. A CTLW or CTLR followed by a CTL, CTLW, CTLR, or SNS.
- 2. A SNS or CPYP followed by any command other than a CPYP, CPYD, TCH, TDC, or LIPT.
- 3. A sns or CPYP followed by a TCH, TDC, or LIPT which transfers control to any command other than a CPYP, CPYD, TCH, TDC, or LIPT.
- 4. A CPYP or CPYD not properly preceded by a CTLW, CTLR, or SNS.

Unusual End

An unusual end indicates an error condition recognized by the control unit. This condition causes an immediate interrupt. The reason for the unusual end may be determined by sensing the control unit error indicators.

Unusual end interrupts may be disabled by the sms command with a 1-bit in position 32. If unusual end signals are inhibted and an unusual end is received, it is treated as a normal end but the unusual end indicator is turned on. A later sms with a 0-bit in position 32 does not reset the indicator and, if not reset by other means (such as an LIP or LIPT command or an RIC instruction), the next end signal (normal or unusual) received from the control unit causes an interrupt. The unusual end interrupt does not occur automatically when the enabling sms command is given. A halt in processing may occur during a CPYP operation if unusual ends are disabled and an unusual end occurs. Examples of error indications that cause this condition are: no record found; file control circuit check; and disk/drum storage circuit check.

If an 1-0 sequence or adapter check occurs during a data transmission operation, the operation is immediately ended with a stop signal and an interrupt occurs when the end signal is received. If an unusual end occurs when transmission is ended, this condition is recognized. The channel does not interrupt twice but has both error indications available for testing during the interrupt routine. Data read or written during an operation that ended with an interrupt may be incomplete or invalid.

Non-Concurrence Interrupt

The unusual end indication may also occur because of a channel condition called "non-concurrence interrupt" (NCI). This feature is enabled or disabled through use of the SMS command. When enabled, an NCI occurs only when the 7909 is actively engaged in reading from an I-O device and any of the following conditions occur:

- 1. The channel is executing a CPYD and the sum of all word counts issued under this select (including the CPYD) differs from the record length being read by a character or more in either direction.
- 2. The channel is executing a CPYP and the sum of all word counts issued under this select (up to and including this CPYP) is such that the end of record being read occurs either before or coincident with count depletion of this CPYP.
- 3. The channel is executing a chain of CPYP commands terminated by a CPYD where the word count of the CPYD is initially zero.

When an NCI occurs, the unusual end indicator in the 7909 is turned on and an interrupt occurs. Sense data (summary byte) may be examined to determine if the unusual end indication resulted from an NCI or an unusual end signal from an input-output device.

Bit 32 of the sms causes both types of unusual end interrupts to be disabled while bit 29 enables only non-concurrence interrupt.

Non-concurrence interrupt allows checking for correct record length or determining the length of the record. To determine the exact word count of a record, a CTLR followed by a CPYD must be executed, and the word count of the CPYD must be greater than the length of the record. The exact length of the record is found by subtracting the starting address specified by the CPYD command from the ending address found in positions 3-17 of the word stored at the interrupt location for the channel in use.

To check for correct record length, the sum of the word counts of all CPYP and CPYD commands must be equal to the expected count of the record, and the terminating CPYD must not have an initial word count of zero. An NCI occurs if the record length differs from the expected record length.

Attention Conditions

This is a signal indicating a change in status of the attached input-output device. During disk or drum operations, an attention signal is generated when an access mechanism has completed a seek operation. The particular access mechanism that generated the attention signal may be determined from sense data. Only one access mechanism is used on the drum.

The single attention indicator in the 7631 File Control, common to all access mechanisms, is reset when the 7909 interrupts. The individual access bits are reset by giving a read, write, or control command to the individual access address.

There are two attention indicators in the 7909. Attention 1 indicates a signal from the device attached to position 1 of the data channel switch feature;

attention 2 indicates a signal from the device attached to position 2.

Either or both attention interrupts may be disabled with the sms command. If attention interrupts are inhibited, the status indicator is set but no interrupts occur and no attention response is sent to the control unit. When an sms that enables an existing attention indicator is executed, the interrupt occurs at termination of the sms, and the attention response is sent to the control unit.

Attention interrupts are serviced only at the logical termination of the command during which they occur. The logical termination of a read or write operation is the disconnect resulting from a CPYD. Attention signals occurring while the channel is in the interrupt mode do not set the status indicators; however, a second interrupt, to service the adapter attention signal, occurs as soon as the channel leaves the interrupt mode. In this case, the channel executes the command following the LIP or LIPT command before interrupting on the second attention signal.

Adapter Check

An adapter check indicates an error recognized by the 7909 and does not necessarily indicate a control unit malfunction. Conditions causing an adapter check are:

- 1. Failure in the 7909 character handling circuitry.
- 2. The character rate of the attached 1-0 device exceeds the capability of the channel.
- 3. The control unit is not operational. This type of indication occurs if power is off in the control unit and an attempt is made to read, write, control, or sense. On shared disk/drum systems, this indication occurs if an attempt is made to read, write, control, or sense and the 7631 is in operation on the sharing system.

If an adapter check occurs while the control unit is selected, the control unit is logically disconnected and the interrupt occurs when the end signal is received.

Input-Output Components

Magnetic Tape Units

As many as ten IBM 729 II, IV, V or VI Magnetic Tape Units can be connected to each 7607 Data Channel on the 7094 system. Tape units may be intermixed, as to type, on the 7094 without addressing changes.

Character Alteration in BCD Mode

As six-bit BCD characters are read from magnetic tape, the zone bits of some of the characters are altered. This alteration is performed so that the digits 0-9 and the characters A-Z are represented in core storage by six-bit binary numbers of increasing magnitude. The alteration of these zone bits is:

	IN CORE STORAGE	ON TAPE
CHARACTERS	в А	ВА
Numeric	0 0	0 0
A to I	0 1	1 1
I to R	1 0	10
S to Z	1 I	0 1

The digits 1 through 9 are represented by the sixbit binary numbers 000001 through 001001; that is, by their exact values as binary integers. Thus, the zone part of the digits is 00. The number zero is represented on magnetic tape by the bit configuration 001010. This representation is automatically altered to 000000 during reading in the BCD mode.

During writing in the BCD mode, the alteration procedure is reversed so that the storage BCD characters are transformed to the BCD tape format by the tape control. In writing, the tape control automatically performs the modifications described but does not check whether the six bits being transmitted form a legitimate BCD character. Thus, if binary numbers are written in the BCD mode, both a pure zero and the number 10 (001010) are recorded on the tape as the BCD zero character (001010). Also, the integer 15 (001111) is identical to the BCD tape mark, signifying an end-of-file condition. Therefore, random binary data should not be recorded in the BCD mode.

In addition to alphabetic and numeric characters, the BCD format provides for punctuation marks and other special characters. Included is the BCD character "blank," which suppresses printing or punching in any desired position during auxiliary operations.

Incomplete Words on Tape

When a tape is prepared by other IBM Data Processing Systems or by an off-line card-to-tape operation, it is possible that some records do not contain an integral multiple of six 6-bit characters. When such a record is read by the computer, the last word of that record is incomplete in that it does not contain six 6-bit characters. The characters making up an incomplete word are placed in the high-order positions of the word location (left-hand positions) and the remaining positions are filled with binary zeros.

When the incomplete word is sent to core storage, the contents of the word counter are reduced by one and the contents of the address counter are increased by one, just as though a full word had been read.

A parity check on an incomplete word is made only when the record is being read in the binary mode. If a disconnect has not occurred before a parity error is detected, the redundancy check indicator is turned on. Checking for this error condition can be blocked by turning the tape word incomplete switch (7617 Data Channel Console) to the PRINT BINARY position.

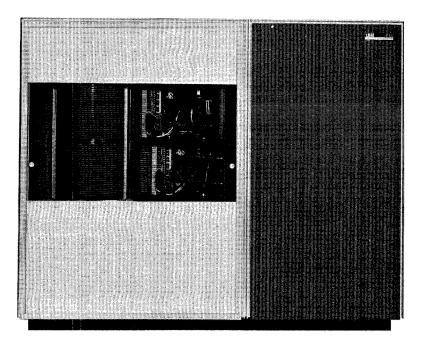

Detailed magnetic tape unit descriptions are in the Reference Manual, IBM Magnetic Tape Units, Form A22-6589.

Disk Storage

The IBM 1301 Disk Storage and IBM 7631 File Control (Figure 60) are available as an optional feature on all IBM 7094 Data Processing Systems. As many as five disk storage units may be attached to one or two file control units. The 7631 is available in five models.

- Model 1: Used with IBM 1410 and IBM 7010 Data Processing Systems.
- Model 2: Used with IBM 7070, 7074, 7080, 7090, 7094 or 7094-II, 7040 or 7044 Data Processing Systems in which the disk storage is not shared.
- Model 3: Used when disk storage is to be shared between a 7000 series system (except 7072 and 7010) and a 1410 or 7010 system.
- Model 4: Used when disk storage is shared by any two 7000 series systems (except 7072 and 7010).
- Model 5: Used when disk storage is shared by two 1410 systems, two 7010 systems or 1410 and 7010 systems.

Disk storage units may be attached to a 7094 system as shown in Figure 61. Other arrangements may be made by using two file control units and two 7909 data channels. For example, three disk storage units may be attached to one file control (and its 7909 data channel) while one or two disk storage units are

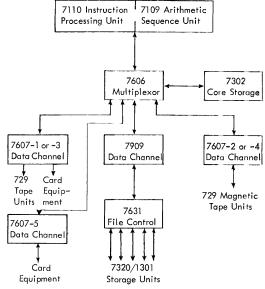

Figure 60. IBM 1301 Disk Storage

Figure 61. IBM 7094 System with IBM 7320/1301 Disk Storage

attached to another file control and its 7909 data channel. Normal data channel addresses are used and, therefore, no more than eight data channels (7607 and 7909) may be used with any one 7094 system.

Each of the five possible 1301 units may have two modules. Within a 1301, the lower module is numbered 0 and the upper module is numbered 1. To the computer, the ten modules are numbered 0 through 9. The access mechanism of each module is numbered 0. A combination of these two numbers is used to select a module and an access. For example, the upper module of the third 1301 in a system is addressed by the number 05.

In writing a format track, inter-record gaps are 12 characters long. On the format track, address and data areas must have the exact character count that will be recorded in the data area, because zero characters are written on the data track for every unused character position on the format track.

Data leave and enter the IBM 7094 as six 6-bit characters in both six-bit or eight-bit mode. When the system is writing in eight-bit mode, two zero bits are added to each character as it is recorded on the disk surface. When the system is reading in eight-bit mode, the same two bit positions are dropped in the data channel and only the six-bit character is read into storage.

Transmission of data to and from disk storage is accomplished by data channel commands. Data transmission is similar to that used by the 7607 channels, except that read and write operations are decoded in the 7909 channel rather than in the central processing

unit. Disk control operations that do not require data transmission are accomplished by sending an order to the file control, where it is decoded and executed. A complete description of these orders and their operation is in the General Information Manual, IBM 1301 Disk Storage with IBM 7000 Series Data Processing Systems, Form D22-6576.

Drum Storage

The IBM 7320 Drum Storage and IBM 7631 File Control are available as an optional feature on all 7094 systems. When used in an IBM random-access storage subsystem, consisting of 7320 Drum Storage and 1301 Disk Storage units, the 7320 permits expanded programming versatility, reduced system loading time, and increased operational efficiency.

The 7320 provides random storage of 1, 118, 400 characters on 400 data tracks. In the normal six-bit data mode, each data track provides bit and character capacities for the recording of data as follows:

Data Bits 16,776 Characters 2,796 (6-bit) Words 466 (36-bit)

The 7631 provides for connection of five random-access storage units. These units may be either 7320 Drum Storage or 1301 Disk Storage units and may be used in any combination, up to the five-unit limit for the system. Two 7631 File Controls may be used, but the limit of five random-access storage units still applies.

For complete information on the 7320 Drum Storage, refer to *IBM 7320 Drum Storage with 7090 and 7094 Systems*, Form A22-6747.

IBM 7340-1 Hypertape Drive

The IBM 7340-1 Hypertape Drive (Figure 62), with the IBM 7640 Hypertape Control, introduces a new concept in magnetic tape devices. Advantages of the 7340-1 tape system are:

Character Rate: As many as 170,000 alphameric characters or 28,330 words per second.

Reel Capacity: In some applications, more than twice that of 729 iv reels (recorded at high density) even though a reel of 7340-1 tape is 600 feet shorter.

Cartridge: Machine and file tape reels contained in a cartridge; result is faster loading and unloading of tape without manual threading of the tape.

Read Backward: Allows a recorded tape to be read backward and eliminates necessity of a rewind operation between successive reads of the same recorded tape.

Faster Access: Average access to records in 4.2 milliseconds.

Checking: Automatic detection of all data errors. Automatic correction of all single-bit errors and most double-bit errors.

File Protection: Cartridge file-protect device under program control.

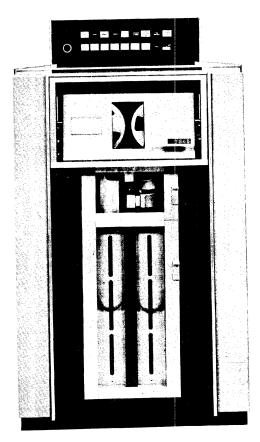

Figure 62. IBM 7340-1 Hypertape Drive

A tape character consists of the information recorded in a bit-wide column across the ten tracks, perpendicular to the edges of the one-inch tape used by the IBM 7340-1 Hypertape Drive. When the 7340-1 is used with the 7094 system, eight of these tracks are used, six for data recording and two for error detection and correction. The remaining two tracks are not used with the 7094 system. Tape track assignments on the 7340-1 for both BCD and binary codes are shown in Figure 63.

	BCD	Code			Binary	Code			
5	Check Bits Not Used		C0 C1	C0 C1	C0 C1	C0 C1	C0 C1	C0 Check C1 Bits Not Used	1
	with 7094	B A 8	S 1 2	6 7 8	12 13 14	18 19 20	24 25 26	\int \text{with 7094} \\ 30 \\ 31 \\ 32 \int \text{Data}	
}	Bits	4 2 1	3 4 5	9 10 11	15 16 17	21 22 23	27 28 29	33 Bits 34 35)

Figure 63. Hypertape Track Assignments

Complete operational characteristics of both the IBM 7340-1 Hypertape Drive and IBM 7640 Hypertape Control are in the IBM 7340-1 Hypertape Drive Reference Manual, Form A22-6616.

The IBM 7340-1 Hypertape Drive and IBM 7640 Hypertape Control are attached to the 7094 System as shown in Figure 64. The 7909 Data Channel is a single-channel device, while the 7640 control is a two-channel device; therefore, simultaneous read-write operation requires that the 7640 be attached to two 7909 Data Channels. As many as ten 7340-1 drives may be attached to each channel of the 7640, making a possible total of 20 drives per 7640 control.

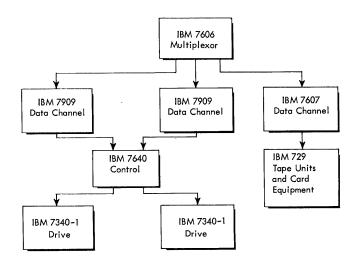

Figure 64. IBM 7094 System with IBM 7340-1 Hypertape Drive

Tape Motion and Markers

A single capstan moves the tape forward or backward at 112.5 inches per second. Rewinding occurs at 225 inches per second with tape in the vacuum columns.

Three markers appear on the tape to set off the recording area from the physical ends. About 15 feet from the physical beginning of tape is a marker called the beginning of tape (BOT). The BOT is adjacent to the machine edge of the tape.

About 15 feet from the physical end of the tape is another marker called the end of tape (EOT). The EOT is the same size as the BOT but is located midway between the edges of tape. Tape motion stops immediately when the machine detects the EOT.

Because the 7340-1 cannot move tape forward past the Eot, a third marker, called the end warning area (EWA) marker precedes the EOT on tape by about 40 feet. The EWA marker is located adjacent to the edge of tape nearest the operator. When tape is being written, detection of the EWA does not stop tape motion but signals the end-of-tape condition.

Optional Features

Two optional features are available for use on the ıвм 7909 Data Channel.

Read Backward Character Assembly and Storage facilitates processing of data received from a recorded tape being read in a backward direction by assembling the characters in reverse order.

BCD Translation Feature accomplishes binary-to-BCD character translation for magnetic tapes prepared or to be used by other IBM Data Processing Systems employing івм 7340-1 Hypertape Drives.

Automatic Cartridge Loader Feature

The Automatic Cartridge Loader Feature may be used with the IBM 7340-1 Hypertape Drive (Figure 65). The automatic cartridge loader attaches to the top of the 7340-1 Hypertape Drive. The 7340-1 operator's control panel is repositioned to the top front of the loader. The combined height of the two units approximates that of an івм 729 Magnetic Tape Unit. With the loader installed, the two units act as one in all operations involving the loading and unloading of cartridges. The loader provides two additional cartridge positions for a total of four.

The four cartridge positions are:

Load Storage: A receiving station for all cartridges to be processed.

Discharge Storage: An eject station. The unload or change cartridge operation moves processed cartridges to this position. Processed cartridges are removed from this position by the operator.

Processing (or Loaded): The normal 7340-1 processing position. Reels are engaged in the drive hubs and tape is in the columns.

Unload (or Ready to Load): The unload or the ready to load position. Tape is out of the columns and the reels are disengaged from the drive hubs.

OPERATIONS

The cartridge loader automatically:

- 1. Unloads a cartridge from the unload position.
- 2. Loads a cartridge into the ready-to-load position.
- 3. Performs an unload-load sequence cycle. It unloads and moves a used cartridge to the discharge storage position, and takes the next cartridge from the load storage position and loads it into the processing position. The complete unload-load cycle time is about 30 seconds.

Operation of the Automatic Cartridge Loader Feature will be controlled by IBM programs supplied with the 7340-1 Hypertape Drive.

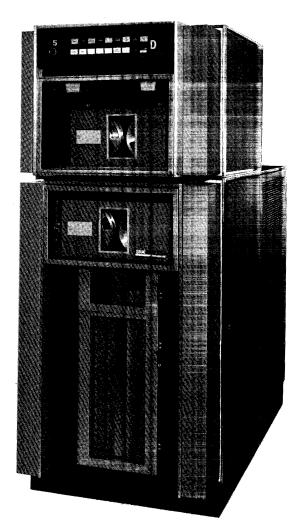

Figure 65. Automatic Cartridge Loader with IBM 7340-1 Hypertape Drive

A door in front of the loader provides access to the load storage and discharge storage position. The operator may open the door to remove or insert a cartridge while Hypertape is being processed, without interrupting processing. Opening the door during a change-cartridge operation stops the action, which is resumed when the door is closed.

Additional information is available in the *IBM* 7340-1 Hypertape Drive Bulletin, Form G22-6667.

IBM 1414 Model 6 Input-Output Synchronizer

The IBM 1414-6 Input-Output Synchronizer connects communication-oriented and paper tape devices to the 7094 System. Attachment to the 7094 is through the IBM 7909 Data Channel. Units that can be attached with the 1414-6 are (Figure 66):

IBM 1009 Data Transmission Unit IBM 1011 Paper Tape Reader

IBM 1014 Remote Inquiry Units

Telegraph Input-Output Units

Six 80-character buffers, each assigned to a specific input-output device, are contained in the 1414-6. The buffers store up to 80 BCD characters and have an average data transfer rate of 11 microseconds per character to and from the 7909. The buffers are under 7094 program control and use normal interrupt procedures.

IBM 1009 Data Transmission Unit

The 7094 System, equipped with an IBM 1009 Data Transmission Unit, may function as a data processor and as a data transmitter or receiver. The 1009 unit allows not only two-way communication between two remote 7090 Systems, but also between a 7094 and an IBM 7701 or 7702 Magnetic Tape Transmission Terminal, an IBM 1013 Card Transmission Terminal, or another IBM system (1400-7000 Series) equipped with a 1009 Data Transmission Unit.

The 1009 Data Transmission Unit has four possible data rates: 75, 150, 250, or 300 characters per second. One 1009 may be attached to the 1414-6 input-output synchronizer and uses two of the six input-output buffers. A detailed description of the 1009 is contained in the Reference Manual, IBM 1009 Data Transmission Unit, Form A24-1039.

IBM 1011 Paper Tape Reader

The IBM 1011 Paper Tape Reader is an input device, controlled by the 7094 program in the same manner as other devices attached through the 7909 Data Channel. The reader operates at 500 paper tape characters per second, using either five-track telegraph or eight-track IBM tape. The tape can be chad or chadless and

in the form of strips, reels, or rolls to be fed from the center.

The 1011 Paper Tape Reader uses one of the six buffers for its operation. One 1011 reader may be attached to the 1414-6. A detailed description of the 1011 is contained in the General Information Manual, IBM 1011 Paper Tape Reader, Form D24-1044.

IBM 1014 Remote Inquiry Unit

The IBM 1014 Remote Inquiry Unit, with typewriter input and output, may be used as a means of system interrogation. The 1014 provides a visual record of information stored in or transmitted from the 7094 System. Remote inquiry provides direct access to any record stored within the 7094 System and furnishes a printed output under program control. The 1014 has a maximum data rate of 12½ characters per second for inquiry request and 15½ characters per second for inquiry reply, with as many as 78 characters per message on input-output operations. The first position of the buffer contains the identification of the 1014 being used. The position adjacent to the last inquiry character is a group mark (‡).

The 1414-6 may have one or two channels (adapters) for attachment of 1014 units. Each channel uses two of the six buffers, one for input and the other for output. As many as ten 1014 remote units are controlled by each adapter. However, only one 1014 per adapter may be in operation at one time. The address of the specific 1014 (0-9) is placed in the first position of the buffer.

The remote inquiry units are cable-connected to the 1414-6 and can be located 8 wire-miles away from the system. (A wire-mile is a parallel set of four wires, or two pairs of wires, one mile long.) For a detailed description of the remote inquiry unit, refer to the "M" Bulletin, IBM 1014 Remote Inquiry Unit, Form G24-1444.

Telegraph Input-Output

As many as four telegraph units¹ may be attached to the 1414-6 to communicate with remote input-output telegraph units. The data transmission rate of these connections can be up to approximately ten characters per second, depending on the transmission rate of the common carrier equipment used. The number of buffers used for telegraph communication equals the number of attached input and output units.

In receive operation, the telegraph units communicate with the 1414-6 by means of five-bit telegraph code. The 1414-6 translates this into standard BCD characters. The telegraph message is divided into two

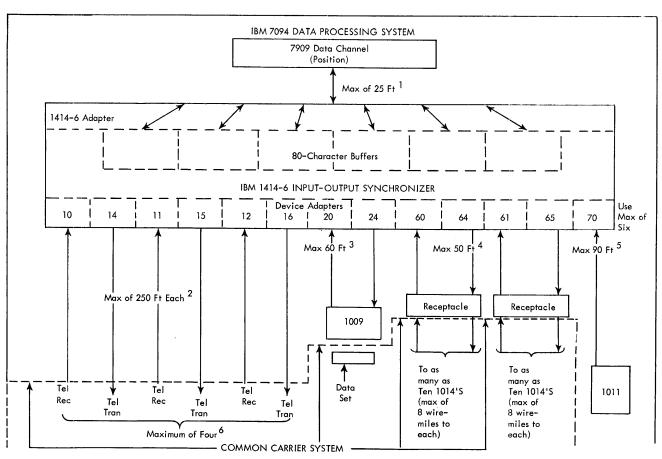

¹ One unit must be a transmitter and one a receiver; the other units may consist of a transmitter-receiver, one or two receivers, or one or two transmitters.

parts, the administrative portion (destination, sending station, date, time, and so on) and the data portion (body of the message). The data portion to be stored in the 7094 must be enclosed by parentheses. It should not exceed eighty BCD characters. With normal input-output programming, the possibility of the data channel being occupied with disk records or the possibility of combinations of other priority-sequenced operations makes it impossible to insure that subsequent buffer-loads of input characters will receive computer attention within the 100 milliseconds (time between characters) allotted for servicing the buffer after it is filled. Therefore, it is strongly recommended that data portions (to be stored) be limited to 80 characters.

The 1414-6 stores only one data portion in one buffer-load. Any additional parenthetical sections occurring within the message will be loaded in the buffer only if the previous data portion has been transferred to the 7909. If disk operations on the same channel or a combination of priorities have prevented the transfer, the new data are not received by the 1414-6.

Before the data go to the buffer, the 1414-6 automatically deletes the letters-shift, figures-shift, line-feed, and blank characters from the incoming message; these characters do not enter the buffer. Optionally, the carriage return and parentheses may be deleted.

In transmit operation, a reverse procedure is followed. Letters shift and figures shift are the only automatically inserted characters. The output message is brought from core storage to the buffer of the 1414-6, translated into telegraph code, and sent to the selected telegraph unit when the line is ready to receive it.

Notes

- 1. Data Transfer Rate--11 Microseconds/Character
- 2. Maximum Data Transfer Rate--Up to 10 Characters/Second
- 3. Possible Data Transfer Rates--75, 150, 250, 300 Characters/Second
- 4. Maximum Data Transfer Rates--12-1/2 Characters/Second (Inquiry Request)
 15-1/2 Characters/Second (Inquiry Reply
- 5. Data Transfer Rate--500 Characters/Second
- 6. One unit must be input and one unit must be output

Figure 66. Configuration of the IBM 1414-6 and Telecommunications Devices

Addressing of Input-Output Devices

Each of the systems adapters attached to the 1414-6 is assigned a two-digit address to identify it to the 7094 program. The first digit identifies the type of adapter; the second digit is the number of that particular systems adapter and indicates the read-write status. Any combination of adapters shown in the following table may be attached to the 1414-6, provided that the combined buffer requirements do not exceed six. Possible input-output adapters, the assigned decimal address, and the number of buffers required for attachment are:

Adapter	Operation	Adapter Address	No. of Buffers Required		
Telegraph	Read Write	10, 11, 12 14, 15, 16	2, 3, or 4		
IBM 1009	Read Write	20 24	. 2		
IBM 1014	Read Write	60, 61 64, 65	2 or 4		
IBM 1011	Read	70	1		
Any combination of the above adapters may be attached to the 1414-6, provided the combined					

Address Register - 1414-6

buffer requirements do not exceed six.

The address register is a two-digit register that stores the address of the selected input or output device. The register is set as the result of a control operation (order) or a 1414-6 internal polling operation to designate a particular device requiring service. This requirement for service is called an *attention*. Attentions are caused by one or two conditions: (1) a write buffer becoming empty² (the empty buffer gives only one attention signal³), or (2) a read buffer being full. The register remains set until the input or output line is deselected (the address register is reset). Resetting the register results from:

- 1. End of read between the 7909 and the 1414-6 buffer (no error).
- 2. End of write between the 7909 and the 1414-6 buffer (no error).
 - 3. End of sense between the 7909 and the 1414-6.
- 4. Start of control operation between the 7909 and the 1414-6.

If read-write operation is terminated with an unusual end signal, the register is not reset and the 1414-6 retains the status information that caused the unusual end. If the program does not interrogate the unusual condition at this time, the information is lost when the next command takes place. While the 1414-6 is retaining status information, attention requests will pile up, possibly leading to overrun conditions in which input information will be lost. A sense instruction should be given immediately after an attention or an unusual end to avoid this possibility.

3 This attention is maintained until honored.

Adapter		STATUS DATA INFORMATION				
Number	Device	A bit - Not Ready	4 bit - Busy	2 bit - Condition	1 bit – No Transfer	
1	Telegraph Read	Buffer not on line or power off	Buffer is being filled	Missed message	No request	
1	Telegraph Write	Buffer not on line or power off	Buffer is being emptied	Last message in error; not transmitted to remote telegraph*	Last message transmitted but received incorrectly	
2	IBM 1009 DTU Read	DTU not on line or power off	Buffer is being filled	Missed message	No request	
2	IBM 1009 DTU Write	DTU not on line or power off	Buffer is being emptied	Last message in error; transmitted to local 1009, but not to remote 1009	Last message transmitted but received incorrectly	
6	IBM 1014 Read	Buffer not on line or buffer power off	Not applicable	Not applicable	No request or buffer being filled	
6	IBM 1014 Write	Buffer not on line or power off	Buffer being emptied	Last message in error; not transmitted	Last message not transmitted station inoperative	
7	IBM 101: Read	Paper tape power offout of tape	Buffer being filled	Not applicable	Not applicable	

^{*} May be transmitted to local telegraph

Figure 67. Detail Status Byte 2, Information

² For 1009 write operation a delay occurs while accuracy of transmission is checked

For proper conditioning of the address register, these rules should be followed:

- 1. A read command or a write command must always be preceded by a control command.
- 2. A sense command must always be preceded by an UNUSUAL END, attention, or a control command.
- 3. An attention or UNUSUAL END should be immediately followed by a sense command to avoid losing real-time data that may be waiting for attention on another line. Also, be sure that the 7094 main program is written so that attentions may be honored immediately.

The control address uses the first digit to indicate the unit and the second digit to indicate the number of that type of unit and the read-write status. The 8 bit of the character is not used in the register. This character bit is not needed because the range of both unit and number is 0-7.

Because of the various units involved, the bit assignment of the second byte is general in nature and has a different meaning, depending on the unit and the type of operation performed. Figure 67 shows the bit error assignments for the different units and operations.

IBM 7607 Data Channels

The IBM 7607 Data Channels (Figure 67) provide the data paths between the IBM 7302 Core Storage and 729 Magnetic Tape Units (except when the 7607 Model 5 is used), the 711-2 Card Reader, 721-1 Card Punch, and 716 Printer. Eight 7607 Data Channels may be attached to a 7094 system. The 7607 contains all registers and controls necessary to read or write information on these input-output units. In addition, the 7607 (except 7607 Model 5) controls all 729 tape positioning operations, such as backspace record, backspace file, and so on.

Configurations of input-output components controlled by івм 7607 Data Channels are:

Data Channel/ Model	Magnetic Tape Units *	Card Reader	Card Punch	Printer
7607 - 1	Ten 729 II, IV	One 711-2	One 721-1	One 716
7607-2	Ten 729 II, IV			
7607-3	Ten 729 II, IV, V, VI	One 711-2	One 721-1	One 716
7607-4	Ten 729 II, IV, V, VI			
7607-5		One 711-2	One 721-1	One 716

^{*}Intermixed in any fashion

Data Channel Select Registers

When a select instruction addressing a tape, card, or printer unit is interpreted in the CPU, it is sent to the specified data channel for execution.

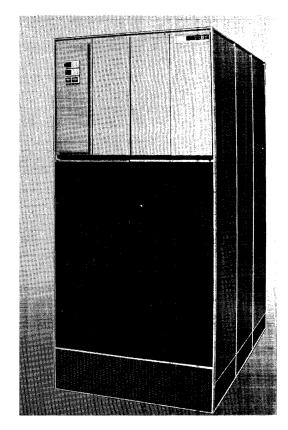

Figure 68. IBM 7607 Data Channel

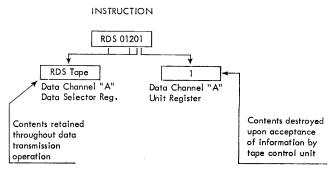

Figure 69. Data Channel Command Stacking, Data Select

If the select instruction is a data select (read select or write select) the instruction is placed in the channel's data select and unit registers. The operation to be performed and the type of unit involved is placed in the data select register. The unit number is placed in the unit register (Figure 69). Once the specified input-output unit has been selected, the unit register is free to accept new information sent from the main

program. The data select register, however, is used throughout the entire input-output operation to control the data channel reading or writing activity. This register cannot accept another data select operation until the present operation has been terminated.

If the select instruction is a non-data select (backspace, rewind, or write-end-of-file instruction) the instruction is placed in the specified data channel's nondata and unit registers (Figure 70). The unit register has the same function as described for a data select. When the data channel executes a backspace record (BSR), backspace file (BSF), or a rewind (REW) instruction, the non-data and unit registers are used only until the tape units have been selected. This requires only a few microseconds. After this selection, the data channel is no longer required and is free to accept any select instruction sent from the CPU. In the case of a BSR or BSF, the execution is completed by the tape control circuits. Any select instruction, addressing a card or printer unit and sent to the data channel before completion of a BSR or BSF, will be executed immediately.

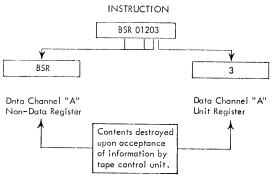

Figure 70. Data Channel Command Stacking, Non-Data Select

The REW operation differs from BSR and BSF in that it uses the tape control for a few milliseconds only. The operation is then controlled by the tape unit that is being rewound. Thus, once a REW has been started, any select instruction which does not address the tape unit being rewound will be executed immediately.

The WEF instruction is similar to a data select in that the specified data channel's non-data register is in use throughout its entire execution.

The data select, non-data, and unit registers of a channel are not directly addressable by the main program. The registers are of importance, however, in terms of synchronous timing relations between the main program and the data channel operation. For example, the outcome of the test made by a transfer-in-operation or transfer-not-in-operation instruction depends solely on the status of the channel's select registers.

Channel in Operation — Not in Operation

The result of a transfer in operation or a transfer not in operation depends on the status of the channel's select registers. If either the data select or non-data register of a data channel is being used to hold information, the data channel is said to be in operation. If neither holds information, the channel is not in operation. Assume that a REW, BSR, or BSF addresses a channel not in operation whose attached tape unit is also not in use. When the execution of the REW, BSR, or BSF has been completed in the CPU and the computer proceeds to the next instruction, the channel remains in use for three machine cycles after which the non-data and unit registers are no longer in use. Then a transfer in operation given before the next select instruction will receive a negative response.

Data Channel Select Instruction Stacking

It is important in input-output programming, particularly with tape operations, to understand the instruction storing or "stacking" abilities of a data channel. Stacking reduces delays in the main program. The conditions described below can occur only when the multiple select instructions address either the same data channel, or a data channel.

The logical independence of each channel assures that the status of one channel is not affected (or does not affect) a select instruction addressing another channel.

When a select instruction is given in the main program and the specified data channel is not in operation, the select instruction is sent immediately to the channel and the main program continues without delay.

If a channel is in operation when a select is given in the main program, the data channel either: (1) does not permit the instruction to be sent, and the main program is delayed until the channel is ready to accept the instruction; or (2) accepts the instruction and stacks it in the select registers until it can be executed. In this case, the main program is not delayed.

Since data select instructions use the data select registers of the specified channel throughout the entire input-output operation, any data select given while another data select is in process will cause the main program to be delayed until the prior operation is completed.

If a data select addresses a card or printer unit, any non-data select given before its completion will delay the main program. This restriction is imposed so that the unit register may be used by the plus sense (PSE) instructions used with the punch and printer units.

Any select instruction given for approximately 50 milliseconds after a WEF operation has started will delay the main program. This implies that no select instruction can be stacked during this time. A WEF may be stacked, however, during the execution of another select instruction.

If a non-data select is given by the main program while the data select addressing a tape unit is in operation, the non-data select will be stacked. No delay will occur in the main program.

As previously indicated, a non-data select, with the exception of WEF, does not require the data channel once the tape unit has been selected. Therefore, any select instruction will be accepted by the channel if given during the execution of a non-data select. If the select instruction addresses a card machine or printer, it will be executed immediately. A select instruction addressing a tape unit will be stacked in the channel and any third select given during this time will delay the main program.

When a RDS or WRS is stacked in the channel, its associated reset and load channel instruction may be executed before it is. When this occurs, the channel command will be held until the input-output unit is ready for transmission. This condition does not disrupt the channel, the check indicator is not turned on and no delay results in the main program.

Programmed Channel Delay

In programming input-output activities, it is frequently desirable to synchronize the testing of the channel indicators with the 1-0 process. The load channel, store channel, transfer in operation, and transfer not in operation instructions provide flexibility in this type of programming.

A simple method which holds the main program at a given point consists of the following. At location Y, a transfer in operation is given the address of Y. Thus the main program will repeatedly execute the transfer until the specified data channel is logically disconnected. It should be noted that a channel is considered in operation as long as any of the select registers contain information. For example, consider the following sequence of instructions:

LOCATION	INSTRUCTION	
100	RTDA 1201	
101	RCHA 0600	
102	BSRA 1203	
103	TCOA 0103	

The BSR instruction located in word 102 will be stacked in data channel A. The program will then delay at location 103 until tape unit 3 attached to data channel A has been selected.

Indefinite Delays

It is possible for a program to cause an indefinite delay in the system as a whole or in an attached data channel by selecting a unit not attached to the computer. If a select, reset-and-load, or load-channel instruction addresses a channel not attached to the computer or one with its automatic-manual switch set to MANUAL, the main program will delay indefinitely attempting to execute the instruction. If the channel is not attached, the select condition may be terminated by pressing the reset key on the console of the CPU. The computer may then be restarted. If the channel's automatic-manual switch is in manual status, when it is restored to automatic status a waiting select instruction will be executed and the program will resume. However, if the waiting instruction is a reset and load or a load channel, the input-output check indicator will be turned on when the channel is restored to automatic.

When (1) any select specifies an 1-0 unit which is not attached to the channel or is not in ready status, or (2) a was specifies a tape unit whose file protect ring has been removed, the select instruction is stacked and the channel will suspend operation indefinitely. The main program may proceed but will be delayed by the next select, or load channel instruction addressing the channel. If the specified 1-0 unit is not attached to the channel, the select condition may be terminated by pressing the reset key on the CPU console. If the 1-0 unit is not ready, appropriate manual service which readies the unit enables both the channel and the main program to continue operation. An exception is when the 1-0 unit is a tape that is not ready because it is rewinding. Upon completion of the rewind operation the tape unit is automatically restored to ready status and the program proceeds.

Figure 71 has been prepared to assist the programmer in determining when a channel is in operation.

Tape Check Indicator

When a transfer on redundancy check is used to test a write operation, it should be preceded by a channel delay instruction. This insures that, when the test is made, all bits including the longitudinal check bits of the last record written will be checked.

If a record or records are read by any combination of channel commands such that the operation is ended following an end-of-record recognition (an IORP command followed by an 10cp with a word count of zero), a similar situation prevails. A channel delay followed by a transfer on redundancy check provides a check on all bits including the longitudinal check bits of the last record read.

Select Operation	Channel In Operation Until	Tape Unit In Use Until
RDS	Last storage reference has been made.	End of record
WRS	Longitudinal check character is read.	End of record
WEF	End-of-file gap and tape mark with its check character read by the read gap.	Same
BSR	Tape control selected.	Beginning of record gap + 25 ms.
BSF	Tape control selected	Beginning of file gap + 25 ms.
REW	Tape control selected	Load point.

Figure 71. Channel Delay Conditions

When word count control is used to govern the reading process (for example, an 10cD command with a word count of N) a channel delay followed by a transfer on redundancy check insures that the N words read the lateral and that only the lateral check bits have been checked. This is true if the record contains more than N words. When the channel word count register reaches zero, the channel has no way of knowing that it has read the last word of a record. The channel disconnect delays until one more transmission point has been reached or the LRCR has been read. However, tape errors occurring in subsequent information (N < number of words in record), including the LRC, will turn on the channel tape check indicator.

End-of-File Indicator

When an end-of-file occurs following an RDS, the channel end-of-file indicator is turned on and the read operation is terminated immediately. Thus, if a channel delay is given at some point subsequent to an RDS and is followed by a transfer on end of file, the transfer condition is met if the channel has been disconnected by an EOF condition.

Such a test has validity only if this indicator is off at the time the RDS is executed by the channel, since this indicator may also be turned on either by other tape units or by a card reader.

Beginning-of-Tape Indicator

The beginning of tape indicator signals that a backspace operation has been completed by reaching load point rather than by sensing the beginning of a record (BSR) or an end-of-file record (BSR). The beginningof-tape indicator may be turned on in the following ways:

- 1. When the tape is at its load point, a BSR or BSF instruction causes the indicator to be turned on immediately.
- 2. When the tape is positioned after any record in the first file: (1) two BSF instructions turn the indicator on if the file was preceded by an end-of-file record, or (2) one BSF instruction turns the indicator on if the file was not preceded by an end-of-file record. In case 1, the first BSF positions the tape over the tape mark in the end-of-file gap, and the second BSF returns the tape to its load point, turning on the beginning-of-tape indicator. In case 2, the first BSF moves the tape backward over the file to the load point, turning on the beginning-of-tape indicator.
- 3. When the tape is positioned after the first record of the first file: (1) three BSR instructions turn the indicator on if the record was preceded by an end-of-file record, or (2) two BSR instructions turn the indicator on if the record was not preceded by an end-of-file record. In case 1, the first BSR moves the tape to the beginning of the first record, the second BSR moves the tape to the beginning of the end-of-file record, and the third BSR moves the tape to its load point, turning on the beginning-of-tape indicator.

To test whether a specific backspace instruction has turned the indicator on, the instruction should be followed by a data or non-data instruction and a channel delay instruction (such as TCOA) before the BTT instruction is used. Once the indicator is on, it will remain on until turned off by the execution of the BTT instruction or a manual reset. The BTT instruction should not be used if more than one tape is being backspaced on the same channel.

End-of-Tape Indicator

The end-of-tape indicator can be turned on only during the execution of a wrs or wer instruction. The specified channel remains in operation throughout the execution of either of these instructions until the tape unit is disconnected. Therefore, the combination of a wrs or wer instruction, followed by a channel delay, followed by an err instruction determines whether or not the end-of-tape marker has been passed at any time prior to the writing of the terminal end-of-record gap.

If the physical end-of-tape marker is encountered while the tape unit is being stopped, the channel's end-of-tape indicator will be turned on but will not be recognized until a succeeding ETT instruction is executed. This situation can occur when the end-of-tape marker falls in an end-of-record gap.

End-of-File Sensing

The wef instruction writes an end-of-file gap and a tape mark (including its check character). End-of-

file gaps recorded with the WEF instruction are not checked for noise, but both the tape mark and its longitudinal check characters are read and both are checked laterally and also longitudinally.

The recognition of an end of file occurs with the execution of a RDS instruction when the end-of-file is spaced over. Assuming that records and an end-of-file have been written on a tape, a program to sense end of file is shown in the example in Figure 72.

ADDRESS	INSTR	RUCTION		COMMENTS
00100 00101	RD\$ RCHA		01202 00500	Select tape 1, channel A Load the IOCD command
00102 00103 00104	TCOA TEFA HTR		00102 01000	Channel delay Transfer on EOF
00500	IOCD	77777 0	05000	Start reading into location 5000
01000 01001	REWA TR		01201	Rewind tape 1 Transfer out

Figure 72. Program Example

With the program shown in the program example, tape records are read into consecutive storage locations beginning with location 5000. When the EOF is sensed, the channel is disconnected and the program executes the instruction at 00102. This instruction loops until the channel is not in operation; then the instruction to test for end-of-file is executed.

Blank Tape Sections

If, at the beginning of a record, no data are provided to be written in that record, a blank section of approximately 3¾ inches will be written. When the blank section has been written (end of record) the channel will either proceed, transfer, trap, or disconnect according to the present command.

Examples are:

- 1. A was instruction not followed by an RCH instruction (or followed by an RCH which loads an IOCD with a word count that is initially zero).
- 2. An IORP or IORT command with word count initially zero that is loaded at the beginning of a record
- 3. A wrs, followed by an RCH referring to an IOCT or IOST command with a word count of zero. If command trap is enabled, the trap will occur after the blank tape section has been written and the channel has left operation.

The blank sections of tape are always read and checked by the read gap of the tape unit. Any noise that is present in the section will turn the tape check indicator on. The channel will remain in operation in all cases until such checking has been accomplished.

To maintain compatibility with 704-type tapes, care should be taken when information is rewritten several times, beginning at some fixed point (other than load point) on tape. The sequence of was and BSR instructions may not be repeated more than ten times. If this limit is exceeded, the record gap preceding the record being rewritten may be lengthened. However, if the record preceding the one being rewritten is always reread by the execution of two BSR's and an RDS before the rewriting, no such restrictions apply. A file may be rewritten from a fixed point (other than load point) only once if the sequence of BSF, WEF, and wrs is used. A wef following the BSF will result in a longer end-of-file gap. If an RDS is used to space over the EOF gap instead of the WEF, the same restrictions do not apply. If the last record of the preceding file is read prior to the rewriting of the file, no such restrictions apply.

A tape may be rewritten in its entirety or from a fixed point forward, but new records and files may not be inserted between existing records and files.

Programmed Interruption of a Data Channel

It may be desirable during the course of a calculation to alter or stop an 1-0 activity. If a reset and load channel is given while an 1-0 operation is in progress. a new command will be loaded into the channel immediately, regardless of the possible loss of data. This feature may be used to change the sequence of or to interrupt an 1-0 operation.

A reset and load channel which loads an IOCD, IOCT. Or IOST command with a zero word count can be used to terminate an I-O operation in progress. For example, a read operation is started by the instructions in location 200 and 201. (Figure 73 shows all addresses and locations in the octal system.) Fifty words are to be read from tape unit 1 into core storage beginning with location 800. Assuming that the read operation will not have been completed when the reset and load channel instruction at location 215 is executed, the disconnect command (location 501) will be loaded into the channel and the I-O operation will be stopped immediately.

LOCATION	INSTRUCT	ION	COMMENTS
200 201	RDS RCHA	1221 0500	Read-select tape 1 Channel "A" Load command into Channel "A"
215	RCHA	0501	: Load command to interrupt Channel"A"
500 501	1OCD 00062 1OCD 00000		•

Figure 73. Programmed Interruption

If a data select instruction is being stacked when a disconnect command is being loaded, the channel is selected, and the execution of the disconnect command is delayed. If a non-data select instruction is being stacked and a disconnect command is loaded, the channel will remain in operation until the non-data select instruction is executed.

If a store-channel is given prior to the execution of an interrupting reset-and-load-channel, a word may be transmitted between core storage and the 1-0 device before the execution of the reset-and-load-channel. This is true even if the two instructions are given consecutively.

Data Channel Timing

Once a channel initiates a storage reference cycle, it will continue to take such cycles until all of its requirements are met. A channel will require one cycle for: (1) each data word transmitted to or from storage, (2) each additional command loaded into it, and (3) indirect addressing of a 7094 command.

When a channel has taken the number of cycles required, a test is automatically made to determine if any other channels require reference cycles. If so, each channel will take, in turn, the number of cycles each one needs.

The requirements for all channels in operation must be met within a period of 26 cycles on the 7094. If this number is exceeded, one or more of the channels will be disconnected and the 1-0 check indicator will be turned on.

EXAMPLE: Channels A and B are to be in operation at the same time. Channel A is controlled by the sequence of commands 10CP, TCH, and 10CD. Channel B is controlled by the sequence of commands 10RP, TCH, TCH and 10CD. Thus, the maximum number of consecutive cycles that may occur is seven (three for channel A—one data-transmission cycle, one command cycle for the TCH, and one command cycle for the 10CD—and four for channel B—one data transmission cycle, two command cycles for the TCH's, and one command cycle for the 10CD).

The maximum allowable program time (in microseconds) between successive load channel instructions for a channel using 729 vI tape units at 800 bits per inch is given by the formula:

$$T_{\rm 1C} = 2[C(26-M)-I-3]$$
 where:

C = word count of the command loaded by the load channel.

M = number of consecutive cycles that may be taken by all channels in operation.

I = 1 if the load channel is indirectly addressed, 0 if not.

EXAMPLE: Channel C is in operation and load-channel instructions are to be used. The commands to be loaded by the load-channel have a word count of two. Further, channels A and B are operating as described in the above example. Thus, the maximum time which may be safely used by the main program between successive load-channels is:

$$T_{1C} = 2[2(26 - 8) - 0 - 3] = 66$$
 microseconds

A data channel relinquishes priority between the time the last word is transmitted by an iocp or iosp command and the arrival of a subsequent channel command. A store channel instruction may, therefore, store an address which is one greater than the address of the last word transmitted by the iocp or iosp command.

Magnetic Tape Timing

Since magnetic tape involves physical motion and mechanical drives, the variations of tape speeds and distances are large when contrasted with speeds in the internal computer.

It is recommended, therefore, that programs use the transfer-in-operation, transfer-not-in-operation, load-channel, and store-channel instructions in synchronizing 1-0 activities rather than depending on the timing associated with physical tape motion.

With respect to timing, select instructions may be regarded as subject to execution at four different levels:

- 1. Initially, the main program executes the select instruction by sending it to the channel. If the channel is not in operation, the main program execution requires two cycles.
- 2. The channel is used by a data select instruction throughout the operation and until the tape control disconnects the tape. The channel is used by a non-data select instruction for stacking purposes only. If the channel is free initially, a non-data select instruction is executed in the channel. The channel remains in use for three cycles.
- 3. Except for a rewind operation, the tape control is in use for most, and in some cases all, of the time that the tape is in motion.
- 4. The time during which the tape itself is in motion is either identical to or exceeds the time in which the tape control is in use.

TIMING, READING AND WRITING

Minimum and maximum times for tape operation differ for writing and reading. During writing, time variations are related only to the duration of the recording pulses. The speed of the tape itself affects only the distances between lateral rows as they are recorded on the tape. During reading, however, variations in the tape drive on the reading unit as well as those which occurred when the tape was written will affect the time of transmission.

If the transfer-in-operation, the transfer-not-inoperation, reset-and-load-channel, load-channel, and store-channel are not used to synchronize 1-0 activities, the following formulas are given for the purpose of calculating the approximate tape passing time of tape files (time in milliseconds):

```
T = .400N + 10.8R + 51F
729 II and V
                 (200 cpi)
729 II and V
                 (556 cpi)
                                  = .144N + 10.8R + 51F
                 (200 cpi)
                                  = .267N + 7.3R + 34F
729 IV and VI
729 IV and VI
                 (556 cpi)
                                  = .096N + 7.3R + 34F
729 V
                                   = .100N + 10.8R + 51F
                 (800 cpi)
729 VI
                                  = .067N + 7.3R + 34F
                 (800 cpi)
```

Where: N = total number of words in all records.

R = number of records involved.

F = number of files or file gaps involved.

Note that if the tape is positioned at its load point when the operation is started, the beginning-of-tape gap should be counted as an extra file gap in computing the value F.

Since a channel is always disconnected when an end of file is sensed and may be disconnected between records, T may represent the sum of several distinct time intervals. During each such interval, both the channel and the tape control, to which the tape is attached, are in operation. The total time during which a tape is in motion may or may not exceed T, depending upon the main program.

TIMING, TAPE CHECK, AND END-OF-FILE INDICATORS

If N in the formula for T is exactly equal to the number of words in one or more records, the longitudinal check bits of the last record will have been read in a time not exceeding T. Discrepancies occurring in or before the longitudinal check bits will have turned on the channel's tape check indicator by T time. Similarly, if N and R represent exactly the number of words and records preceding an end-of-file gap, then the expression for T with F=1 (F=2 if the tape was initially at its load point) yields the time that may elapse before the channel's end-of-file indicator is turned on.

TIMING, RESET AND LOAD CHANNEL

Once the execution of a WRS or RDS instruction is begun in a channel, a reset-and-load-channel must supply the channel with a command before the tape is ready to send or receive the first data word. The minimum time within which the instruction must be given depends on whether a WRS or RDS is specified and the position of the tape when selected. Time is in milliseconds (ms).

		TIME WITHIN	WHICH
INSTRUCTION	TAPE POSITION	RESET-AND-LOAD	-CHANNEL
STARTING TAPE	WHEN INSTRUCTION	MUST BE	CIVEN
MOTION	IS EXECUTED	729 II, v	729 iv, vi
WRS	Not at load point	4 ms.	2.7 ms.
WRS	At load point	30 ms.	20 ms.
RDS	At load point Not at load point	1 ms.	.7 ms.
RDS	At load point	15 ms.	10 ms.

The read gap is positioned $\frac{3}{10}$ inch behind the write gap and must read the longitudinal check bits before the channel can disconnect and receive a select for the next record. During reading, the first word of the record is sent to the channel and then to a storage location as soon as the channel can make a storage reference cycle. During writing, however, the first word to be written is taken from storage at the time the reset-and-load-channel is executed. It is held in the channel until the tape is positioned to write the first character of the word.

TIMING FOR BSR, BSF, AND REW

The following table may be used to assist in calculating running time involving backward movement of tape. The time required to backspace the tape over a record, file, or to rewind the tape to its load point may be computed by adding:

- 1. Time to start tape moving in a backward direc-
- 2. Time to space the tape, and
- 3. Time to stop the tape.

The times, which may depend on the status of the tape, are given below and are average times:

```
N = .400 × number of words

= .144 × number of words

= .267 × number of words

= .096 × number of words

= .100 × number of words

= .067 × number of words

= .067 × number of words

= .067 × number of words

= .400 × number of words

729 II and V (200 cpi)

729 IV and VI (200 cpi)

729 IV and VI (556 cpi)

729 V (800 cpi)

729 V (800 cpi)
```

The time to backspace over r records (BSR) containing n words may be calculated as follows:

```
\dot{T}r = 54r + Tn \ (729 II and V)

Tr = 36r + Tn \ (729 IV and VI)
```

The time required to backspace over f files (BSF) containing r records and n words may be calculated as follows:

```
Tf = 94f + 10.8r + Tn (729 II and V)

Tf = 63f + 7.3r + Tn (729 IV and VI)
```

If a rewind is given for a tape positioned more than approximately 450 feet from its load point, then about 1.2 minutes are used by the high-speed rewind operation. For a tape positioned at its load point, none of

the backward moving select instructions cause tape motion. However, they may use the tape control from 25 to 3,000 microseconds in testing the load point condition. Consequently, a following tape select instruction using the same channel may be subject to a slight delay.

KEEPING A TAPE IN MOTION

Once started, the tape moves at a constant speed until a channel command causes a disconnect or an EoF is encountered. The tape continues its motion to the middle of the end-of-record gap and then stops. If a was or RDS for the next record has been issued by the main program and is awaiting execution when the tape is ready to stop, the new select instruction will be in effect and the tape motion will continue at full speed.

Failure to keep a tape in motion will not increase the total running time of the program.

If the tape receives a new select instruction while it is slowing, acceleration occurs again. The tape drive is designed so that regardless of the tape motion when it begins acceleration, the time taken to reach the beginning of the next record is constant.

Similarly, when a tape is to stop, the time taken to move from the end of the last record to the point on the tape where the tape control disconnects the tape is constant (approximately 2.5 and 4.25 ms. for the read and write gaps, respectively).

Scheduling Simultaneous I-O Operations

The following procedure permits determination of the number of 1-0 devices that can operate simultaneously without loss of data caused by failure to gain access to a core storage cycle. (No one channel may have more than three consecutive storage cycles.)

- 1. Select the desired devices and their respective weights from the following table.
- 2. Assign the devices with the greatest weights to the channels with the highest priority. Channel priority is assigned by an interconnecting priority cable and may be in other than alphabetic (A to H) sequence.
- 3. If a channel has various devices attached, with different weights, assign the highest weight to the channel.

If the sum of the weights is less than or equal to 100, the combination will operate without loss of data. If the devices with the greatest weights are not assigned to the channels with the highest priority, the total allowable weight is limited to 70.

	CHARACTER	WEIGHT PER
DEVICE	rate (kc)	CHANNEL
729 II, V (200 cpi)	15	1.9
729 IV, VI (200 cpi)	22.5	2.8
729 II, V (556 cpi)	41.7	5.2
729 V (800 cpi)	60.0	7.6
7750	71.5	7.6
729 IV, VI (556 cpi)	62.5	7.9
1301	90	9.6
1414-6	90	9.7
729 VI (800 cpi)	90	11.7
7340	170	23.0
7320	202.8	25.0

7094 Examples

PRIORITY SEQUENCES	DEVICES	WEIGHT ASSIGNED
1st	7340	23.0
2nd	7340	23.0
3rd	729 VI (800 cpi)	11.7
4th	729 VI (800 cpi)	11.7
5th	1301	9.6
6th	1301	9.6
7th	729 IV, VI (556 cpi)	7.9
		96.5

This combination will operate without loss of data.

PRIORITY		WEIGHT
SEQUENCES	DEVICES	ASSIGNED
lst	7340 and 1301	23.0
2nd	7340 and 1414-6	23.0
3rd	1301 and 729 V (800 cpi)	9.6
4th	720 V (800) and 729 VI (800 cpi)	11.7
5th	729 II (556) and 729 IV (200 cpi)	5.2
		72.5

This combination will operate without loss of data.

Card Reader

One IBM 711 Card Reader (Figure 74) may be attached to any channel on the system.

The 711 reads cards at a rate of 250 cards per minute. Cards to be read are placed in the feed hopper face down, 9-edge first. Information punched in the cards may be decimal, alphabetic, binary, or any special character code. The reading format is controlled by the stored program and a control panel located on the reader. With a 711 Reader attached to a channel, a 716 Printer must also be attached to the same channel because power is supplied to both the reader and punch from the printer.

The reading of cards is started by the execution of an RDS instruction addressing a channel and an attached reader. Physical motion in the reader is started and within 55 ms. (following the RDS), a reset and load channel instruction must supply the channel with its first command. Any sequence of commands calling for the uninterrupted transmission of at least 24 words causes the reading of the entire card. The words are transmitted in the order: 9-row left, 9-row right through 12-row right. For example, if an IOCD command with a word count of 24 is initially executed,

the 24 words are read from the card in the indicated order and stored in 24 consecutive core storage locations beginning at the address specified by the command. After execution of the IOCD command, the channel and the reader will be disconnected. With a word count of less than 24, only the specified number of words is read into core storage, the channel and the reader are disconnected, and the remaining words are spaced over without being read. With a word count greater than 24, the channel reads from successive cards until the word count is zero. Words on a card may be read into non-consecutive locations through use of an IOCP, IOCT or other count control commands which do not necessarily disconnect when the word count reaches zero.

Commands specify record control functions exactly as they do for tape records. Thus, an iorr command with a word count of 100 reads the entire card (24 words) after which an end-of-record occurs in the reader and the channel proceeds to its next command in sequence. For an iorr command with a word count of 1, the channel reads the 9-row-left word, spaces over the remaining 23 words, and, as the card reader end-of-record occurs, proceeds to the next command in sequence.

When the hopper of the reader becomes empty, operation is suspended in the reader and channel. The channel read-write register is in use throughout the delay period. The main program is delayed if another select instruction addressing the channel in question requires execution. If additional cards are placed in the hopper and the reader start key is pressed, normal reading will continue. If no additional cards are

placed in the hopper and the operator presses the reader start key, the remaining cards which have not been read (last two cards) are read in a normal manner. If the card reader and channel are selected after the last card is read, an end-of-file indicator in the channel is turned on and both devices are disconnected.

Card Reader Timing

NOTE: In the following card machine descriptions, all times shown on the timing circles are minimum times with single-channel operation. Minimum time is defined as the maximum allowable time between consecutive load channel instructions and includes the time necessary for the execution of the load channel instruction.

In continuous reading, cards are processed at a rate of 250 per minute. The timing of a card cycle is shown in Figure 75.

If the reader is disconnected between two cycles, the new RDS for the second cycle must be given in the hatched portion of the cycle to insure continued reading at full speed. The reader speed is constant if the new select is given within 30 ms. following the reading of the 12-row right. If the select is given between 30 and 90 ms., a delay of 60 ms. is imposed before reselection occurs. Card reader speed will be reduced to 200 cards per minute if this is done continuously.

When the select is given in the hatched portion of the cycle, a reset and load channel must supply the channel with its first command within 85 ms. following the 12-row right transmission. This provides for

Figure 74. IBM 711 Card Reader

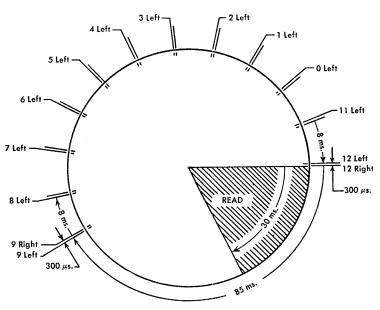

Figure 75. Card Reader Timing Circle

safe timing, as the average elapsed time between the 12-row right for one card and the 9-row left for the next is 108 ms.

When the card reader is not in motion and the first RDS is executed, the position of the reader with respect to its cycle is arbitrary. Hence a reset and load channel must be executed within 55 ms. although the 9-row left transmission will not occur, on the average, for 110 ms.

The times at which successive left and right words are transmitted to storage are shown in Figure 75 by the designations 9-left, 9-right, and so on. The minimum times between word transmissions (300 µs. between left and right words and 8 ms. between the right word of one row and the left word of the next row) should be considered when load channel instructions are used to synchronize the CPU and the reader. For example, assume that a reset and load channel has supplied the DSC with an IOCT command whose word count is one. This command sends the 9-left word from the reader, through the channel, to the location in core storage specified by the address field of the 10CT command. The word count is reduced to zero when the word enters storage. At this time a load channel instruction must be waiting in the main program. Assume that another foct command with a word count of one is loaded in the channel, and that such a command is sent to the channel at every transmission point. Then the times between transmission (alternately 300 µs. and 8 ms.) would represent the maximum allowable times between consecutive load channel instructions.

When the word count of an IOCD command is reduced to zero, the reader is disconnected on what would have been the next transmission point. A reset and load channel which loads an IOCD, IOCT, or IOST command with a zero word count may be used to terminate an I-O operation. If the RCHA is given within 125 microseconds after any read-right transmission point, or 925 microseconds after an end-of-record

point, the card reader will immediately disconnect. If RCHA is given later, the disconnect occurs at the next transmission or end-of-record point (even if this next point occurs on the following card).

Timing Chart

When the reader is operating at normal speed each cycle requires 240 ms. The cycle is divided into 360°. One degree corresponds to an average time of ½ ms. The card reader cycle is also divided into 20 cycle points (18° for each cycle point). The beginning or end of most impulses coincides with a cycle point. The relation between the timing chart (Figure 76) and the timing circle shown in Figure 75 is as follows:

The 9 row of the card passes under the reading brushes at 9°. Whenever holes are punched in the 9 row of the card, impulses which last until 18° are available at the corresponding read brush hubs. With any 72 read brush hubs wired to the 72 calc entry left and right hubs, these impulses are transmitted in the form of two 36-bit words, to the channel and then to some core storage locations. Transmission points occur between two and three ms. after the reading brush falls into the hole punched in the card. (The contents of the word register in the channel are also reduced at this time.) Thus, the 9-left and 9-right transmission points occur at 12° or 13°. Each read brush impulse has a duration of 9°.

The end of the record occurs at 224° and the endof-file indicator is turned on, after the last card is read, at 7° of the following cycle.

When the reader is disconnected it continues to move through its cycle until 330° (asterisk on the timing chart); at this point the feed unit is latched or locked in position. The driving mechanism continues to turn, however, and when a new RDS is executed the mechanism turns until it reaches one of four possible unlatching positions. At this point a new card reader cycle begins. The beginning point is always 330° because of an interlock.

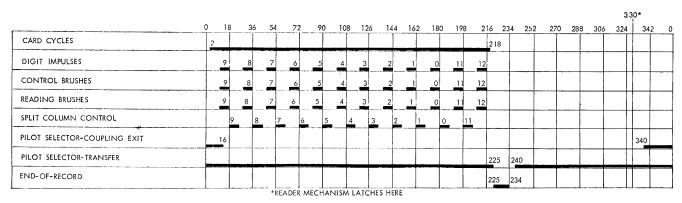

Figure 76. Card Reader Timing Chart

Card Punch

One IBM 721 Card Punch (Figure 77) may be attached to any channel on the system.

Punched card output may be decimal, alphabetic, binary, or any special character code. Information is punched at the rate of 100 cards per minute. Cards to be punched are placed in the punch feed hopper face down, 9-edge first. The punching format is controlled both by the stored program and a control panel located on the punch unit. Data channels having a punch attached must also have a 716 printer attached.

Basic operations are analogous to those of the reader, except that instead of building up a card image in core storage with information read from a card, the channel sends a card image from core storage to the punch to be recorded on a card.

Punching is started with the execution of a was whose address specifies a channel and attached punch. Physical motion is started in the punch by the was execution, and within 70 ms. an RCHA in the main program must supply the channel with its first command. The punch will be disconnected if this does not occur; then when the reset and load channel is executed (if no other channel component is selected) it will turn on the 1-0 check indicator on the com-

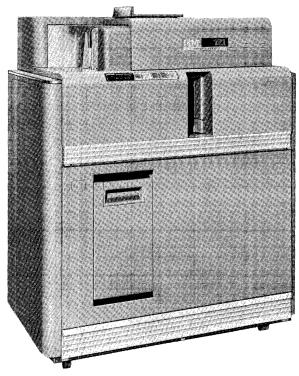

Figure 77. IBM 721 Card Punch

puter console. Although any sequence of commands might follow as a channel program, assume that only one order (an 10cd with a word count of 24) is executed. Starting with the location specified by the IOCD command, 24 words from consecutive locations in storage are punched as the 9-row left, 9-row right, through the 12-row right of the card. The specified card columns punched are controlled by the control panel wiring; the 36 calc exit left and the 36 calc exit right hubs may be wired to any 72 of the 80 punch magnet hubs. Each of the 72 bit positions in a pair of left and right words of the card image then correspond to a particular column on the card. Thus a l in position S of the third word transmitted causes an impulse to appear at the calc exit left S hub. If this hub is wired to punch magnet position 1, a punched hole in row 8, column 1 of the card results.

Punch Timing

During continuous punching, cards are processed at a 100 card-per-minute rate. A punch cycle is illustrated in the timing circle shown in Figure 78.

If an IOCD command causes a punch to disconnect at any time during or after the punching of a card, a new was must be executed within 25 ms. following transmission of the 12-right word to the punch (before the end of the hatched portion) if the 100 cardper-minute rate is to be continued. If this is done an RCHA must supply the channel with its first command for the new cycle within 95 ms. following the 12-right word transmission to the punch for the previous cycle. If the punch is disconnected and a new was is executed after the end of the hatched portion of the cycle, the punch may have mechanically latched or stopped. In this case punch motion has ceased except for the drive mechanism, which coasts to a stop. Motion is resumed when the new select is executed, but approximately one revolution may be required before the drive reaches a point where it will unlatch the punch.

When the punch is at rest and the first was is executed, the drive is positioned arbitrarily. An RCHA must always supply the channel with its first command within 70 ms. If the RCHA is not given soon enough, the punch and channel may be disconnected, in which case the RCHA will turn on the 1-0 check indicator. The minimum time between word transmission (300 μ s. between words and 31 ms. between rows) should be considered when load channel instructions are used to synchronize the punch with the CPU.

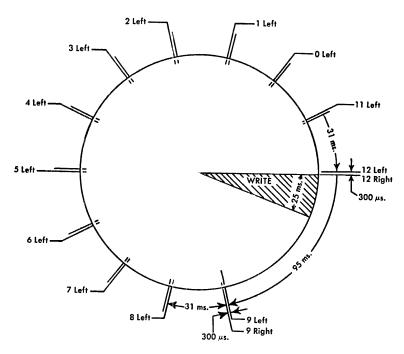

Figure 78. Card Punch Timing Circle

Timing — Channel Commands

It is important to note that the points designated as 9-left, 9-right, and so on, in Figure 78 represent times at which card image words are sent from the channel to the card punch. Using load or store channel instructions, these times may be taken as cycle points that afford the main program the means of identifying which phase of a punch cycle is in process at any given time. Note the following properties of the channel which may be relevant in this regard:

- 1. As soon as a word is sent to the punch, the next word to be transmitted is sent to the channel. The channel address and word count registers are increased and decreased, respectively, by one. Thus the Nth point on the timing circle represents the time:
 - a. the Nth word is sent to the card punch.
 - b. the N-plus-1 word is sent to the channel.
 - c. the contents of the address register are increased to the N-plus-2 word address.

When an RCHA is executed, the first command and the first data word specified by the command are sent to the channel. The contents of the word register and address register are stepped down and up by one. These actions in the channel are all started by the RCHA execution, and all take place before the next instruction is executed in the main program. The foregoing account applies only to the punch, but is applicable to other 1-0 units during write operation.

2. The loading of the first command and first data word when a reset and load channel follows a was is

such that, once a cycle has been taken for a storage reference, the channel continues to take successive cycles until all of its logical needs have been met. For example, when a TCH command is received by the channel, the next command (address of the TCH) is taken from core storage during the next storage cycle. Furthermore, all needs for storage cycles in all channels must be satisfied before the main program is permitted to make another storage reference.

- 3. An exception to the channel's tendency to take new data or command words at the earliest possible cycle is the load-channel instruction. This exception is illustrated by an 10cr command given during writing. In accordance with item 1 above, the word count will be reduced to zero when the last word has been sent from core storage to the channel, but before the last word has been sent to the punch. The channel does not look for a waiting load-channel instruction in the main program until the word count is zero and the last word has been sent to the punch.
- 4. When an 10CD punch command is executed, the punch is disconnected and the channel drops out of operation when the word count plus one transmission point has been reached.

Items 3 and 4 may be summarized as follows: An loct command with a word count equal to N words forces the channel to look for a waiting load channel instruction in the main program at the Nth transmission point (Figure 78). An locb command with a word count of N words results in a normal disconnect at the N+1 transmission point.

5. An end-of-record occurs approximately at the end of the hatched portion of the cycle, no sooner than 20 ms. and an average of 25 ms. following the transmission of the 12-right word to the punch. The end-of-record condition in a punch, occurring at the 25th transmission point, is similar to an end-of-record gap on tape. Unlike tape, card equipment has no means of writing an end-of-file.

A reset and load channel instruction which loads an IOCD, IOCT, or IOST command with a zero word count may be used to terminate an I-O operation. If the RCHA is given within 925 microseconds after any transmission or end-of-record point, the card punch will immediately disconnect. If RCHA is given later, the disconnect occurs at the next transmission or end-of-record point (even if this next point occurs on the following card).

Timing Chart

A simplified timing chart of the punch is shown in Figure 79. The basic cycle of 600 ms. is broken into 14 subsections, divided by cycle points numbered 12, 13, 14, 9...12. Cycle points 9 through 12 denote the times at which pairs of words are sent from the channel to the punch for normal row-at-a-time punching. More exactly, points 9 through 12 stand for the time at which the left word of the row is sent to the punch, with the right word following in about 300 μ s. (Figure 78.

Cycle point 13 represents the time at which an endof-record condition occurs. Notice that cycle point numbers correspond to card row numbers. Numbers like 14.5 or 9.5 are to be taken as points standing halfway between 14 and 9 or between 9 and 8. The fractional part of a number always implies an extension to the right of the cycle point. This left-to-right orientation may also be thought of as the direction in which the cycle actually progresses in time. The point D (denoted by *) indicates the starting point of the cycle. The timing chart shown in Figure 79 should not be used as a mechanical reference. The card punch is effectively locked at point D whenever it is not in motion.

Impulses shown in the timing chart are:

Card Cycles. Each feed cycle, an impulse is available at these hubs.

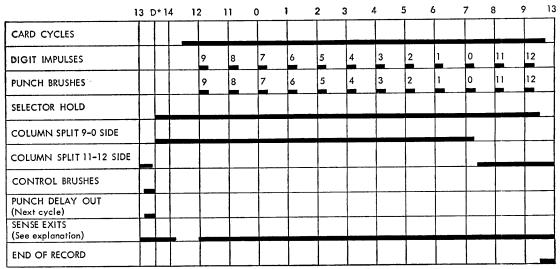

Digit Impulse. These impulses are available each feed cycle.

Punch Brushes. These impulses are available when the card is read by the punch brushes. A card passes over the punch brushes and is read during the cycle following the one in which it was punched.

Control Punches. Control punches in the 8 row of a card are sensed and produce impulses at these hubs on a punch cycle. Six such control brushes are available and may be manually set to read any six of 80 card columns.

Punch Delay Out. An impulse is available on the punch cycle following the cycle in which a control punch is sensed if the control brush is wired to a punch control IN hub.

Column Split. The column split acts as an internally wired selector that transfers from the 9-0 side to the 11-12 side after 0.4 time on the timing chart. The contacts return to their normal side at 13.4.

^{*} PUNCH MECHANISM LATCHES HERE

Figure 79. Card Punch Timing Chart

Selector Hold. The 10-position selectors are of the immediate pickup type. Whenever a selector pickup hub is impulsed, its contacts transfer and remain transferred until 12.5 of the punch cycle, at which time the common hubs are again connected to the normal hubs. If, however, at 12.5 the pickup hubs are still impulsed (by a sense exit, for example), the selector remains transferred until 12.5 of some succeeding punch cycle.

Sense Exits 1 and 2. Impulses are made available at these hubs through the execution of appropriately addressed PSE instructions in the main program. In general, synchronous relation between the CPU and the punch need not concern the programmer unless PSE instructions are to be used to pick up selectors or exert some control over punching operations. Points of interest regarding the execution of a PSE which addresses a sense exit hub on the punch are:

- 1. When addressing the punch, a PSE must be given while the channel is in operation and the punch is selected; i.e., the order must be executed after an initial WRS in the main program and before a disconnect occurs in the channel. Otherwise, the PSE has no effect and is treated as a no-operation.
- 2. When the punch is not in motion and the first was is executed, the feed is effectively locked at "D" (Figure 79). The cycle does not start until the arbitrarily positioned drive mechanism has moved to the latch point and the feed becomes unlatched (able to move). If a PSE is given immediately following the initial was, the impulse is available before the punch cycle has started.
- 3. Under the circumstances indicated in item 2, the impulse is emitted from the sense exit hub from the time the PSE is executed to 14.2, and from 12.6 through 14.2 of every cycle thereafter, until the punch is disconnected. Once the punch is disconnected, the impulse is not available until another identically addressed PSE is executed. Thus, if an IORP command is followed by an IOCD with a zero word count, the punch is disconnected at 12.6 (end-of-record) and the sense exit impulse is no longer available. If a was is executed immediately after the disconnect, punching continues without losing the next cycle. Notice that if it is desirable to use sense exit impulses during some cycles but not during others, some scheme such as that described in the preceding explanation is necessary to terminate the hub's impulse without terminating continuous punching.

- 4. A PSE instruction executed between 14.2 and 14.9 causes an exit impulse to be emitted at the end of that cycle and on all succeeding cycles from 12.6 to 14.2.
- 5. A PSE instruction, given any time at cycle point 9 or later, causes an impulse to be emitted from the appropriate sense exit within 6 ms. and lasting until 14.2. The impulse will be repeated in the usual manner until the punch is disconnected. On the last cycle of punch operation a PSE should not be programmed after 9 time. Once the impulse is emitted it remains active until 14.2 of the next cycle, even if the punch is disconnected. Internal damage may occur if the emitting impulse is present at the sense exit hub throughout a period when the punch is not in use.

Printer

One IBM 716 Printer (Figure 80) may be attached to any channel on the system.

The printer is equipped with 120 rotary type wheels (Figure 81). Each wheel has 48 characters including numerals, alphabetic symbols and special characters (Figure 82). Use of the stored program enables the computer to print any desired information in any form convenient to the programmer. This information is printed at the rate of 150 lines per minute. Printing format is controlled by the arrangement of the information in storage and by a control panel located on the printer.

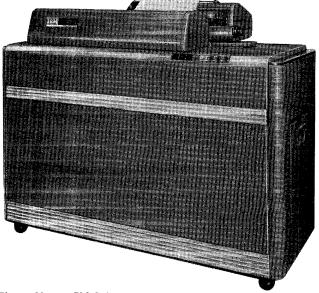

Figure 80. IBM 716 Printer

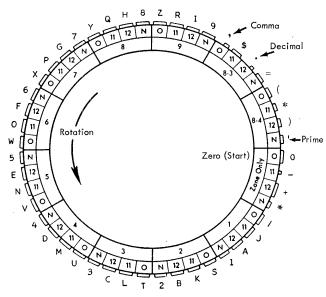

Figure 81. Type Wheel Schematic (FORTRAN)

A line is printed in a time period which is called a print cycle. During this interval the type wheel is rotated until the specified character is centered in front of the platen and then printed. The amount of rotation, and consequently the character printed, depends on the time in the print cycle when the electrical impulse initiates motion. For example, if a print wheel receives an electrical impulse during that part of the cycle designated as 9 time, the number 9 is printed. Also if the print wheel receives an impulse at 1 time and an impulse at 12 time, the print unit positions the wheel to print the letter A (according to the standard IBM code shown in Figure 83).

Printing is similar to tape and card operations with respect to the role played by the channel to which the printer is attached. A printer record corresponds to a single printed line or to the information in core storage necessary to print one line. An end-of-record condition occurs at the end of each print cycle. Consequently, all eight channel commands are available for use in a print program.

Printing a Line

To initiate printing, a was with a normal address specifying a channel and its attached printer may be

digit	no (N) zone	12 (Y) zone	11 (X) zone	0 zone
no digit		+	_	0
1 2 3 4 5 6 7 8 9 8-3 8-4	1 2 3 4 5 6 7 8 9	A B C D E F G H I	J K L M N O P Q R \$ *	/ S T U V W X Y Z

Figure 83. Punched Card Code (FORTRAN)

employed. Physical motion in the printer is caused by the wrs and within 58 ms. a reset and load channel must be executed to supply the channel with its first command.

If an 10cD command with a word count of 24 is given, the channel synchronizes itself with the printer and sends 24 words from consecutive locations in core storage, each at an appropriate time, to the printer; thus one line will be printed. The characters which are printed are determined by the contents of the 24 words in core storage.

The first two words are sent to the printer at 9time in the printer cycle. If both words contained all 1's (S, 1-35) and all other words in the card image contained 0's, the number 9 would be printed in 72 positions on the same line. The printer control panel has 72 hubs (calc exit left and right) which correspond to the 72 bit positions of the pair of words transmitted from core storage. Wherever a bit position in the first word contains a 1, an impulse is emitted by the corresponding calc exit left hub; likewise a bit in the second word creates an impulse at a calc exit right hub. The 72 hubs may be wired directly to any 72 of the 120 print entry hubs. Impulses sent to the printer via these hubs control the type wheels directly and cause specific characters to be printed. Thus, through wiring between the calc exit and the print entry hubs, each of the 72 bits from a pair of words in core storage may be made to correspond to a particular type wheel.

Zone Digit	12 None	12 8 - 3	12 8-4	11 None	11 8-3	11 8-4	0 8 - 3	0 8-4	0 1	None 8-3	None 8-4

Figure 82. Alternate Type Wheel Characters

The print cycle, as it progresses, goes through points designated 9-time, 8-time, ...0-time, 11-time, 12-time. These times are analogous to those of the standard 407 that operates from card reading. At each time point, the next pair of words from a 24-word record in core storage are sent to the printer. The 24 words are designated 9-left, 9-right, and so on, corresponding to the time points at which they are sent to the printer. The record comprises a card image of exactly the type obtained by reading a card into consecutive core storage locations with each pair of words corresponding to a card row.

Note that the character printed by a given type wheel is determined by the contents of a fixed bit position in every other word of the record. Thus, if the 1-left and 12-left words have one bits and all other left words have zeros, the type wheels associated with the bit positions will print the letter A.

Printing Multiple Lines

If the word count of an 10CD command is greater than 24, additional lines may be printed. The 25th word is taken as the first word of the card image for the second line of printing; i.e., the 25th and 26th words are sent to the printer at 9-time of the second print cycle and successive words will be sent to the printer and printing will continue until the word count reaches zero. When the count reaches zero, the printer is disconnected from the channel and, if no other operation is waiting, the channel drops out of operation. If this occurs in the middle of a card image, the line is printed as though all of the missing portion of the image contained zeros.

In general any command or sequence of commands may be used in sending words to the printer. An endof-record condition occurs following the transmission of every 24 words.

Printing with Checking

The previous statements describe printing without checking. Checking is possible because the printer can not only receive print impulses from the computer but can also send back "echo impulses" generated by the individual type-wheel position. Printing with checking requires a somewhat more complicated program, but can be accomplished without reducing the 150-line-per minute printing speed. Via control panel wiring, echo impulses may be returned to core storage in word groups which are similar to the words that

were sent to the printer to be printed. The stored program can then compare the image transmitted against the image received, to insure that the type wheels were correctly positioned. During the first half of the print cycle words are sent to the printer, and during the last half of the cycle the echo words are returned from the printer. These two time periods overlap somewhat, so that echo words begin returning from the printer before all print words have been sent. The general sequence of events in a print cycle with echo checking is as follows:

- 1. An RDS instruction addressing a channel and its attached printer is given to initiate the first print cycle.
- 2. Within 58 ms. a reset and load channel must be executed, thus supplying the channel with its first command.
- 3. As in printing without checking, 12 pairs of words (forming the 12 rows of the card image) are taken by the channel from storage and are sent to the printer, where they determine which characters are printed. Nine pairs of echo words, similar to rows 9 through 1 of the original image, are sent from the printer back to core storage. In the standard IBM code, the digits 8-3 and 8-4 (with or without zone punching) are used for special characters. Two additional pairs of echo words provide a check that the correct print wheels have received these impulses. As a result, for all positions in the original image where both 8 and 3 rows (or 8 and 4 rows) contain 1's, the 8-3 (or 8-4) pair of echo words will contain 1's. A single type wheel causes the emission of only one echo whenever it prints a character. Zone (0-11-12) printing is not echo checked. If such characters requiring both a zone and a digit impulse are printed, only the digit impulse may be echo checked.

In printing with echo checking, an end-of-record condition occurs after 46 words have been transmitted (24 words from storage and 22 echo words returned). The exact sequence of transmission is: 9-left through 1-right written; 8-4 left and right echo words received; 0-left and right words written; 8-3 left and right echos received; 11-left and right words written; 9-left and right echos received; 12-left and right words are written; 8-left through 1-right echos received.

It is possible for the main program to compute throughout the cycle. If the channel is operated through an 10cD command with a word count of 46, it is necessary to stretch the image out over a 46-word block of storage, reserving appropriate locations for the returning echo words. By using a sequence of commands, it is possible to print an image of 24 words and also direct the echo words to any other configuration of storage locations.

Printing More than 72 Characters per Line

Through use of selectors or column splits on the printer control panel, storage can activate more than 72 print wheels. For example, seven 10-digit numbers with signs can be printed. Additional characters can also be printed by impulses emitted by the printer itself. The control panel may also be wired so that 120 characters originating from storage can be printed on each line at the rate of 75 lines per minute, with two print cycles being required for each line of printing. Normal spacing of the printer must be suppressed before the second cycle.

Timing without Echo Checking

Continuous printing occurs at a rate of 150 lines per minute, each line requiring one normal print cycle. The timing of such a cycle is shown in Figure 84. If the transmission of the 12-right word causes the channel to drop out of operation, the next was must be given within 115 ms. following the 12-right transmission, to keep the printer in continuous motion. The reset and load channel which follows the select must be given within 173 ms. of the 12-right transmission to supply the channel with its first command for the second print cycle. These minimum times allow for the safe timing, as the average elapsed time between the 12-right transmission of one print cycle and the 9-left transmission of the next cycle is 216 ms.

In general, it is not necessary to give a new select for each print cycle. Any desired sequence of commands may be used to print lines continuously and an IOCD command will terminate printing when it is executed by the channel. The channel to which the printer is attached remains in operation during the printing operation. The time between print cycles is sufficient to permit the execution of some other 1-0 operations through the same channel with no interruption in the 150 line speed. When another 1-0 operation is used between the printing of two lines, it is necessary to disconnect the channel following the last word transmission to the printer and to issue a new wrs during the hatched portion of the cycle for printing of the next line.

Printer Disconnect

An 10CD with a word count of 24 disconnects the printer on end-of-record. An 10CP with a word count of 24 and an 10cp with a word count of zero disconnects on the 12-row right. An 10cT with a word count of 24 and without a load channel waiting also disconnects on the 12-row right. As the disconnect occurs, the channel is taken out of operation. Any select instruction (including the was for the next print cycle) issued while the channel is still in operation delays the main program until the printer disconnects and frees the channel to accept a new select. An loco command may be used to disconnect the printer before 24 words have been transmitted. For this operation the channel drops out of operation one cycle point after the last word is sent to the printer. When the channel drops out of operation, the printer itself remains in motion. It is for this reason that a new was issued at any point in the hatched portion of the cycle enables printing to continue at maximum

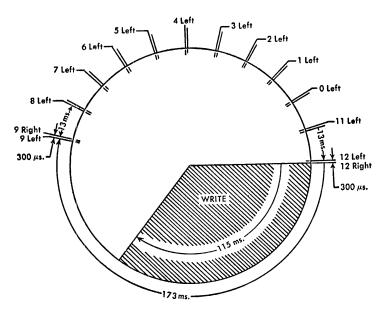

Figure 84. Printer Write Timing Circle

speed. A new wrs, given more than 115 ms. after the 12-right transmission, may find the print unit latched. In this case printer motion has ceased except for the drive shaft (which coasts to a stop). The shaft will resume full speed when the new select is executed but will require about one revolution in which to return to a point where it can latch with the print unit again. Thus, the effect of giving a wrs too late is to lose one print cycle. This affects printing speed and may affect control panel wiring, but no logical interference with the main program or the channel is entailed.

A similar timing situation is involved when the printer is not in motion and the first was is executed. The drive shaft will be at an arbitrary position. If the shaft is positioned just before the latch point, the print cycle may be started within a few milliseconds. In terms of the cycle shown in Figure 84, this corresponds to a was given at the end of the hatched portion. Because of this possibility, a reset and load channel must always be given within 58 ms. following the first was. The average elapsed time between the first was execution and the 9-left transmission to the printer is 280 ms. If a reset and load channel is not given soon enough, the printer and the channel may be disconnected. A late reset and load turns on the t-o check indicator.

Other minimum times shown in Figure 84 should be considered when using load channel instructions to synchronize the main program and the printer. For example, assume that a reset and load channel loads an 10cT with a word count of one. This command sends the 9-left word to the channel. At 9-left time this word goes to the printer. A load channel must be waiting in the main program. If the waiting load instruction then loads the printer channel with the same command, a second load channel must be given within 300 microseconds. If the same 10cT command is loaded for each word transmitted in the image, then a total of 23 load channels are required.

Timing of Data Channel Commands

It is important to note that all points on the timing circle of Figure 84 represent times at which card image words are sent from the channel to the printer. Other events which come into play at this time are:

1. When one card image word is sent to the printer, the next word is sent to the channel. The channel address register and the word count register are increased and decreased, respectively, by one. Thus, the Nth point on the timing circle represents the time at which the Nth word is sent to the printer, the N+1 word is sent to the channel, and the address register is increased to the address of the N+2 word.

2. A general principle of channel design is that, once a cycle has been taken for a storage reference, the channel continues to take storage cycles until all of its needs are met. For example, during a write operation, when an IOCP command is executed and the last data word enters the data register, the contents of the word register go to zero. At the next transmission point the contents of the data register are sent to the printer. At this point a storage cycle is started to bring the next command from storage and is followed by another storage cycle to bring in the next data word.

During a read operation, when an 10CP command is executed and the last data word enters the data register, a storage cycle is taken to store the contents of the data register. During this cycle the contents of the word register go to zero, thus starting another storage cycle to bring in the next command. Similarly, when the TCH command is received by a channel, the command specified by its address field is immediately loaded into the channel (followed by the first data word). Furthermore, if more than one channel is in need of storage references at one time, then all such references will be made.

- 3. If synchronous operation with the main program is involved, action in the channel is not always immediate. During a write operation, as indicated in item 1, when the word count has been reduced to zero, the last data word (subject to the current command) has been stored in the channel but has not been sent to the 1-0 device. With an 10CT command being executed after the last word has been written, a waiting load channel will then be executed. With one reset and load channel and 23 load channels, both conditions (word register equal to zero and the data word sent to the 1-0 unit) are met at each transmission point before a new load channel can be executed in the main program.
- 4. Similarly, if an 10CD command is executed, the printer is disconnected and the channel drops out of operation when the transmission point of word count plus one has been reached.

A reset and load channel instruction which loads an IOCD, IOCT OF IOST command with a zero word count may be used to terminate an I-O operation. If the RCHA is given within 925 microseconds after any transmission or end-of-record point, the printer will immediately disconnect. With RCHA given later, the disconnect occurs at the next transmission or end-of-record point (even if this next point occurs on the following print cycle).

5. An end-of-record condition in a print cycle occurs no sooner than 13 ms. after the 12-right trans-

mission. At this time any end-of-record response specified by the current command is made.

Although the instruction was has comparable meanings for both magnetic tape and printers (words are sent from storage to the 1-0 device) the execution of commands of the record control type differs during writing, depending on whether a tape or printer is selected. During a print cycle, an end-of-record condition always occurs at a fixed point of the cycle. If the command (write end-of-record) with a word count of 2 is given to the printer, this will result in printing the 9 row. The remainder of the print image will be skipped over and the next command will not be brought into the channel until the end-of-record occurs.

Write Binary

The address of a wrs printer instruction may specify binary printing. After such a select has been issued, no words are transmitted to the printer until 1-time. Two words, corresponding to the 1-left and 1-right rows, are sent to the printer. This results in the printing of 1's by the type wheels, corresponding to the non-zero bit positions of the two words. On each cycle, only these two words are sent to the printer, so 0's can be printed by control panel wiring only. The transmission of such words during binary printing is accomplished through execution of channel commands in the usual way. The end-of-record occurs the same as with the write printer operation.

Timing with Echo Checking

As shown in Figure 85, the timing of a print cycle with echo checking is similar to that of one without it. Following the first RDS, an RCHA must supply the channel with its first command within 58 ms. The time point at which the 24 card image words are transmitted to the printer are unchanged by use of echo checking. With echo checking, however, 22 additional transmission points occur to provide for the echo words. If the printer is disconnected after the last transmission (1-right echo), a new RDS must be given within a minimum of 12 ms. (hatched portion) if printer motion is to be continuous. When an IORP or iort command is used, the channel remains in operation and approximately 16.3 ms. (and no sooner than 12 ms. after 1-right echo) an end-of-record occurs. In general any number of printed lines may be echo checked following the execution of a single RDS. An RDs addressing a channel and attached printer represents the only instance in which a select instruction initiates both writing and reading.

If an 10cT command with a word count of N is the first command executed in a print cycle, a waiting load channel is executed at the Nth transmission point, whether this specifies the transmission of an echo word or a print image word.

Note: Position 19 of the command, indicating non-transmitting mode, is effective only on read printer operation and provides a useful method for skipping the 8-4 and 8-3 rows of numerical printing (assuming that these rows are not used for sign printing).

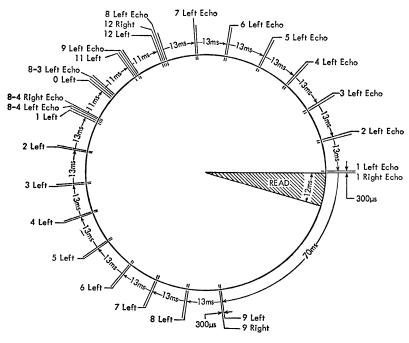

Figure 85. Printer Read Timing Circle

Programming Examples

A computer program is similar to the program received at baseball games, concerts, and many other presentations in that it is a plan of operations or events that will occur. The process of getting to work each morning may be compared to a program concerned with the following problem: Compute A + B - C and store the result (D), if it is a plus number; if minus, halt the computer (Figure 86).

Block diagrams, also called flow charts, are a schematic diagram of the logic of the computer and methods it uses in solving a problem. The main reason for a flow chart is that it is easier to write and understand than a written paragraph about the problem. The flow chart is a map of all logic paths and decisions used by the computer, and simplifies the writing of a coded computer program.

The same program used in Figure 86 may be expressed in program terminology as shown in Figure 87. Given: Factor A stored in location 100, factor B in 200, factor C in 300.

The instruction location designates the place, in core storage, where the instruction is stored. The instruction abbreviations are such that they represent the actual operation involved. For example, sub means subtract and sto means store, while CLA means clear the register to zero and add. The address part designates a location in core storage where a number is located or where a number may be stored. Thus, the operation of the program would proceed as follows.

The program is started with the first instruction (CLA 100) which is contained in location 0000. This instruction will clear the accumulator register to zero and then bring the contents of core location 100 into the accumulator (factor A). The next instruction (ADD 200) will bring factor B from storage and com-

Instruction Location	Instruction	Address
Move A	CLA ADD SUB STO	100 200 300 400

Figure 87. Simple Program

bine it with factor A. The third instruction (SUB 300) brings factor C from storage and subtracts it from the combined factors A and B. The fourth instruction then takes the result in the accumulator and stores it in storage location 400. Thus D has been formed and stored.

A possible use of two of the shifting instructions is shown in Figure 88 with the following facts known. Two numbers are contained in the same storage location. One number is located in positions 6 through 20, and the other is in positions 21 through 35. (Assume that this word is already located in the accumulator.) The problem is to multiply the number in positions 6-20 by the number in positions 21-35.

Location	Instruction	Address	Comments
0000	LRS	0015	Move positions 21-35 into the MQ.
0001	RQL	0016	Align this number in proper place to be used as the multiplier.
0002	STO	0100	Store the multiplicand so that it may be used in the multiplication.
0003	MPY	0100	Multiply the two numbers.
0004	STQ	0200	Store the result. (STQ is used because the result is small enough to be completely contained in MQ.)

Figure 88. Multiply and Shifting Problem

Conditional transfers may be used to solve the following type of problem. Assume that A and B are two positive numbers located in storage at locations 100

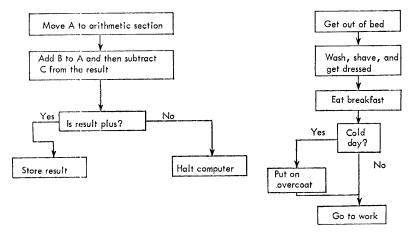

Figure 86. Simple Program Analogy

and 101. The problem is to find the smaller number and put it in location 200; also, to place the larger number in 201. If they are equal, put one number in 200 and nothing in 201. The computer program is shown in Figure 89.

The use of index registers can be pointed up by showing the number of program steps saved, and thus also computer time saved. Given numerical constants in locations 1 through 50, with a 1 in location 100, the numerical value 50 in location 200 and the value 50 stored in location 300. The problem is to add 1 to each of the 50 constants. Figure 90 shows the problem solved without using index registers. Figure 91 shows the same problem solved with index registers being used. The advantages and flexibility of indexing are readily evident.

Figure 91. Address Modification with Indexing

Another programming aid which permits the changing of an instruction's address is indirect addressing. Bits in positions 12 and 13 denote indirect addressing. They are signified in the instruction format by an "F" and in programs and text by an asterisk following the instruction code (CLA*). One additional computer cycle will be taken whenever indirect addressing occurs. During this cycle the word located at the instruction's address is brought out of storage and its address is used to locate the word upon which the instruction operates. This is sometimes called "the second effective address."

As an example of the feature's use, assume that a word has been read into storage by an input-output device. The programmer knows that the command which read in the data is in location 0100. To bring the data back into the accumulator, a portion of the program could be as shown in Figure 92.

The indirect addressing feature may also be combined with indexing, as mentioned above, to obtain a second effective address.

Location	Instruction	Address	Remarks
0077 0100	XXX I-O	xxxx	Previous command Input-output command
0200	CLA*	0100	The CLA* would bring in the data serviced by the I-O instruction even though the address portion is not known.

Figure 92. Indirect Addressing Example

Definition of an Assembly Program

An example of an assembly program is one that defines the symbols and their use as follows:

- 1. The general format of each instruction is: LOCATION, OPERATION, ADDRESS, TAG, DECREMENT.
 - Only those instructions that are referred to by other instructions in the program need be given a symbolic location. All other instructions may be written leaving the location field blank. If the tag and decrement fields are not used, they are left blank. In the case of instructions such as CAQ and VLM, the count is placed in the decrement field. Also, for these instructions, if a tag is not required the instruction would be written in the form operation, address, o, count.
- 2. A symbolic address or location can be composed of one to six alphamerical characters, one of which must be non-numerical. For example: TEMP1, GO, HALT, X1 are all allowable symbols. Thus, each symbol can have an important

mnemonic value. Six special characters may not be used in a symbol. They are +-*/, and \$. These characters are used for special operations. For example, the plus sign is used for the addition of two or more symbols and/or numbers. Such an operation might be A1 + A2 or HALT + 3.

- 3. When dealing with a block of data words, only one location in the block need be assigned a symbol. For example, if a block of data words consisted of A1, A2, . . . A75, the location of the first word of the block could be given the symbol AONE. All other words in the block would be related to this point. If A23 were to be referred to it, would be by the symbol AONE + 22.
- 4. When the actual value of an address, decrement, or count is known, it should be written in absolute form.

When the program has been written it is prepared for assembly by punching each instruction and piece of data into a separate IBM card. These cards are then referred to as symbolic cards.

This symbolic deck is converted to magnetic tape through the card-to-tape equipment and entered, along with the assembly program, into the computer. If desired, the symbolic program may be entered directly into the computer through the on-line card reader.

Assembly

In the assembly process, the symbolic instructions are processed as follows:

- 1. The symbolic operation codes are replaced with the actual patterns used by the computer. For example, CLA is replaced by the combination of bits 000 101 000 000 which occupy positions S, 1-11 of the 36-bit instruction word in storage.
- 2. The absolute location for the first instruction of the program is determined by the programmer and given to the assembly program. Each succeeding instruction and data word is given an absolute location stepped up by one. It is therefore important that the symbolic deck be in the proper order. Each symbolic location detected by the assembly program is entered into a table (called the symbolic table) along with its assigned absolute location. The assembly program then replaces the symbolic address with the absolute locations from the table.

Normally, as a product of the assembly program, a listing of the program in the symbolic format and the actual machine language program is made. In addition, the assembly program furnishes the programmer with a deck of cards containing the machine language program.

Logical Check Sums

One of the principal methods of keeping a check on a block of information in storage is to attach to this block a sum value of all the words in the block. This sum is called the check sum. The best possible check sum that can be formed is one that is developed using the logical operations of the computer. This check sum is known as a logical check sum. It is normally not equal to the algebraic sum of the block. When using a logical check sum there is no possibility of overflow as in the case of algebraic sums. Furthermore, it does not matter in what direction the words of the block are added. This is not true in algebraic summation where overflow possibilities are affected by the direction of summing. An example of the computing of check sums is shown in Figure 93. The programmer knows that there are five blocks with nine words in each block. The first block starts at location 0601, the second at 0611, the third at 0621, and so on. Location 0500 contains a 9 and location 0501 contains a 49. The problem is to find the logical sum of each block and place it in the first location preceding that block.

The coding of a program instruction normally follows this sequence: (1) the location of the instruction, (2) the instruction mnemonic, (3) the address, if any, (4) the index register, if any (5) the decrement. Thus a TIX, 1000, A, 1 would mean that the TIX transfer address is 1000, index register A is to be used, and a decrement value of 1 is involved. The location of the instruction would precede the TIX.

The program shown in Figure 94 will compute the logical check sum for a block of 300 words in core storage. Assume that the 300 words are located in storage in locations 700 through 999. The resulting check sum is to be stored in location 1000. The program uses an index-register-controlled loop to form the logical check sum. The contents of index register 1 are used to effectively modify the address of the instruction in location 102. The index register initially contains the number 300. The final value in the index register will be 1 since the decrement of the TIX instruction is 1. The manner in which the two-instruction loop is performed is as follows:

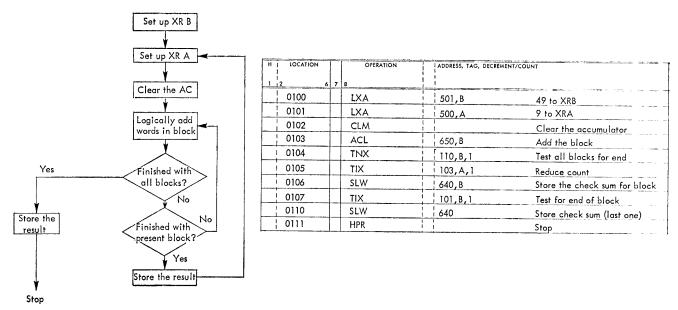

Figure 93. Computing Check Sum Program and Flow Chart

	xr. 1	EFFECTIVE ADDRESS OF
LOOP CYCLE		ACL INSTRUCTION
End of 1st cycle (Before TIX executed)	300	ACL 700
End of 2nd cycle (Before TIX executed)	299	ACL 701
End of 3rd cycle (Before TIX executed)	298	aci. 702
End of 299th cycle (Before TIX executed)	2	aci. 998
End of 300th cycle (Before TIX executed)	1	acl 999
End of 300th cycle (After TIX executed)	1	Not executed

Normally a symbolic location is assigned to the block of words. For example, the symbol first could be used to designate the location of the first word of the block. The symbol cksum could be used to specify the location where the computed logical check sum is to be stored. The program would then be written as shown in Figure 95.

The number of times the loop is executed is dependent upon the value placed into the index register and the value of the decrement of the TIX instruction. In the preceding example, since XRA contained 300 and the decrement of the TIX instruction is 1, the loop is executed 300 times. If the decrement had been 2, the loop would have been executed 150 times. In this case the logical check sum would have been com-

Figure 95. Logical Check Sum Program, Symbolic

puted for every other word in the block. Note that at the end of the 300th cycle the index register contained 1. The contents of an index register are never reduced to zero as the result of using a TIX or TNX instruction. The final value found in an index register is dependent on the decrement of the TIX or TNX instruction. If the decrement is the integer K, then, depending upon the initial value of the contents of the index register, the final value of the index register can vary in the range K, K-1, K-2, , 3, 2, 1.

One of the ways check sums could be used is shown in Figure 96. The problem is to find the logical sum of a block of seven numbers starting in location 0100. If the sum does not equal the predetermined amount in location 0200, transfer to an error stop. If it does equal the amount in 0200, proceed with the program. The first check sum (original) is in location 0200, and a 6 is in the address part of location 0006.

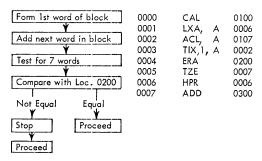

Figure 96. Use of Check Sums and Tests

Packing and Unpacking

There are many cases where the information to be handled by the computer is made up of individual items, each of which is less than the size of a computer word. For example, it may be necessary to work with numbers no larger than three decimal digits. To conserve storage space, three such numbers can be stored in the same word as illustrated in Figure 97, where positions S, 14 and 25 are the sign posi-

Figure 97. Diagram of Packed Word

tions of the numbers N_1 , N_2 , and N_3 , respectively. Handling of information in this manner is called "packing." In addition to conserving storage space, packing also increases the entry and exit speed of information by reducing, for instance, the amount of magnetic tape which must be read or written.

Assume that a word in core storage has the form shown in Figure 97, and the number N2 is to be operated upon. Before arithmetic operations can be performed with this item, it must be separated from the other data in the word. The method of doing this is called unpacking. The logical operations are employed in this type of operation, as they provide a powerful and flexible tool for carrying out the method. The number N2 is to be unpacked from the word without destroying the numbers N1 and N3. Therefore, the unpacking will be done in the accumulator, saving the packed word in core storage.

The program shown in Figure 98 will accomplish this. The mask used in the program contains 1's in positions 14-24 and 0's elsewhere. The result of using this mask with the ANA instruction will place the number N2 in positions 14-24 of the accumulator. By varying the format of the mask, any of the three numbers could have been unpacked (extracted) from the packed word.

MASK	ост	777760003777	MASK TO REMOVE N2 FROM LOCATION PAKWD		

Figure 99. Packing Program

After performing the desired arithmetic operations on the number N2, a new number, N4, is the result. This number is the same size as N2. Now this new number is to be packed (inserted) in location PADWD replacing N2. N1 and N3 are to remain unchanged. The program in Figure 99 will accomplish this. The program assumes that the number N4 occupies positions S, 1-10 of location Locn4. The mask used with the ANS preserves the numbers N1 and N3 while replacing N2 with 0's.

Masking may be used to extract a full number or portion of a word from a given location instead of shifting and adjusting the result. Another example is shown in Figure 100 where a number located in positions 12-35 of location 0100 is to be extracted and stored in location 0200. The mask used is located in 0050 and consists of zeros in positions S-11 and ones in positions 12-35.

The program example in Figure 101 shows a number of test instructions, the compare instruction, and some arithmetic operations. The instruction PRINT means that a print routine is being used and the data being printed are denoted by its address.

The problem is to divide A by B. If the computer cannot handle the problem, print both A and B. If the answer equals 7000, multiply it by C and save the answer in location 0400. If it is less than 7000, print the answer. If it is more than 7000 put the difference in location 0500.

The programmer is given A in location 0100, B in location 0101, C in location 0102, and 7000 in location 0103.

Again the flow chart should serve as an aid in the program steps and is a reference when reading the program.

Figure 100. Masking Program

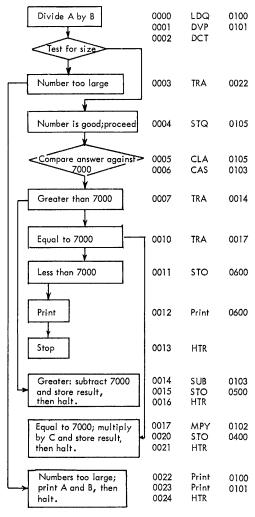

Figure 101. Program Example

An example of input-output and computing is shown in Figure 102. There are eight binary records on tape unit 1 attached to channel A. Each record contains ten words. The program should: (1) skip the first three records, (2) skip the first five words of the fourth record, (3) read the last five words of that record, (4) skip the first five words of the fifth record, and (5) read the last five words of the fifth record. Put the ten words read into binary print using the printer attached to channel C. Simultaneously with the reading, solve $(B + C) \times D$ and store the result in 0110 and 0111. B is in location 0200, C is in location 0201, and D in location 0202.

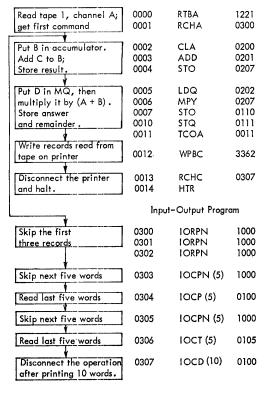

Figure 102. Simultaneous Read, Write and Compute, then Print

Subroutines

It is very often necessary to repeat the same group of instructions many times during the execution of a program. Examples are the series of instructions necessary for decimal-to-binary conversion, square root, or computing a logical check sum. It is not desirable to write out the necessary instructions each time a function is needed. Instead, the instructions needed are written only once and the main program is then arranged to transfer to this block of instructions each time they are required. Such a block of instructions is called a "subroutine."

These subroutines normally perform such basic functions that they may be used in the solution of many types of problems. For instance, a subroutine which computes a square root can be used in a wide variety of problems. Another example of such a subroutine would be one which computes the logical check sum for a block of words in storage.

Subroutines may be used in two ways with respect to the main program. One method is to insert the subroutine into the main program at the point where it is to be used. Subroutines designed for this type of usage are called "open-subroutines." The open subroutine is "sandwiched" into a program as though it were part of the original coding of the program. This type of subroutine usage is normally restricted to the cases where the main program uses the subroutine only once.

When the main program uses a subroutine several times, which is the common situation, it is apparent that the open subroutine is not desirable. Here, the second method of employing subroutines is used. The subroutine used in these situations is called a "closed subroutine." A closed subroutine may occur several times within one main program, but the set of instructions comprising the subroutine need appear only once. The transfer of control from the main program to the subroutine takes place from a set of instructions known as the calling sequence or basic linkage. The calling sequence transfers control to the subroutine, tells the subroutine where to return to the main program, and gives the subroutine any other information required (Figures 103 and 104).

The subroutine illustrated computes the logical check sum for a block of words in core storage. Three parameters are needed by this subroutine. There are the initial location of the block, the number of words in the block, and the location for storing the resulting check sum. The subroutine then returns control to the main program at the instruction following the last parameter of the calling sequence.

The calling sequence is of the form shown in Figure 103. The subroutine is of the form shown in Figure 104.

The complete transfer of control between the main program and the subroutine is based upon the TSX instruction. As the result of the execution of this instruction, the twos complement of the location LINK is placed in index register 4. From the standpoint of algebraic operation the twos complement of a number is equivalent to the negative of the number. For example, 1 minus (twos complement of LINK) is equivalent to 1 minus (minus LINK) = 1 + LINK.

н	LOCATION	Γ	OPERATION		ADDRESS, TAG, DECREMENT/COUNT		COMMENTS	IDENTI- FICATION

	STSUM		SLW		0	STORE CHECK SUM IN LOCATION CKSUM			
			TRA		4,4	RETURN CONTROL TO MAIN PROGRAM			

Figure 104. Subroutine to Compute Logical Check Sum

In the subroutine the instructions which make use of this property are:

INSTRUCTION	EFFECTIVE EXECUTION	EQUIVALENT EXECUTION
CLA 2,4	CLA $2 - (2$'s comp. LINK)	CLA LINK + 2
ADD 1,4	ADD $1 - (2's \text{ comp. Link})$	ADD LINK $+1$
CLA 3,4	cla 3 - (2's comp. link)	cla link $+3$
TRA 4,4	TRA $4 - (2's \text{ comp. LINK})$	tra link $+4$

From the above table it can be seen that the subroutine will be able to make use of the information found in the parameter locations of the calling sequence without knowledge of their exact location in storage. Since LINK is a symbol representing any location in core storage, the subroutine can thus communicate with the main program at any location in the main program. By means of the TRA 4,4 instruction, the subroutine has the ability to transfer control back to the proper location in the main program.

One of the main responsibilities of a subroutine is to insure that when control is transferred back to the main program the status of all the registers is the same as when control was transferred to the subroutine. This does not apply, of course, to a subroutine designed specifically to change a machine condition. For example, in the previous illustration the contents of index register 1 are destroyed by the subroutine. Thus, when control is transferred back to the main program, index register 1 may not be the same as when control was transferred to the subroutine. The contents of index register 1 may be preserved by adding the instruction sxa save, 1 just after the instruction CLA 2, 4. The contents of XR 1 will be stored in the address part of location save. Now, if location save is inserted just before the TRA 4,4 instruction and contains the instruction AXT 0,1, the original contents of xR 1 will be replaced just before control is transferred back to the main program.

Convert Instructions

Three convert instructions are available in the computer. During their execution these instructions use, in addition to core storage, the accumulator, multiplier-quotient, and storage registers. Index register 1 may also be used, if desired, to receive information at the conclusion of a convert instruction execution. These instructions normally work with tables stored in core storage.

These convert instructions provide the programmer with a rapid means of performing such operations as

BCD-to-binary and binary-to-BCD conversion, BCD arithmetic, editing of records, and modification of collating sequences.

When the convert instructions are used, either the AC or the MQ contains a 36-bit word that is divided into six 6-bit binary numbers. Each 6-bit number (sometimes referred to as a character) is treated separately in consecutive order by the convert instructions. For the instructions CRQ and CVR, this 36-bit word represents the actual word operated upon. The CVR examines the word six bits at a time from right to left, while CRQ examines the word six bits at a time from left to right. For the CAQ, the contents of the MQ are examined six bits at a time from left to right while addition of quantities found in core storage, as determined by this word in the MQ, takes place in the AC.

The problem of replacing the leading zeros of a BCD number with blanks is reduced to a short rapid program through the use of the CRQ instruction. This particular convert instruction is used because, to remove leading zeros, the BCD number must be tested from left to right.

To carry out the editing (modification) of the BCD number, it is necessary to set up a table in core storage. This table has the following format:

LOCATION	CONTENT	rs
	S, 1 - 5	21 - 35
A	BCD blank (b)	A
A + 1	BCD one	A + 10
A+2	BCD two	A + 10
		•
•	•	•
A + K	BCD (K)	$\dot{A} + 10$
•		•
•	•	•
	· .	
A + 9	BCD nine	A + 10
A + 10	BCD zero	A + 10
A + 11	BCD one	A + 10
A + 12	BCD two	A + 10
•	•	
•		•
•		•
A + 19	BCD nine	A + 10

The program shown in Figure 105 will perform the required editing operation on a BCD number of 12 digits occupying two consecutive core storage locations. The program must consider the following cases:

- 1. All leading zeros must be sensed and replaced by blank characters.
- 2. All non-zero digits must be preserved.
- 3. Once a non-zero digit is found, all succeeding zeros must be preserved.
- 4. If a non-zero digit is found in the high-order six digits, the second half of the number need not be processed.

The program is executed as follows: The highorder six digits of the BCD number are placed in the MQ by the LDQ BCDl instruction. The first table reference made by the CRQ A,1,6 instruction will be at location A + N, where N is the high-order digit in the MQ, that is, $C(MQ)_{S,1-5}$. If N is zero, the CRQ instruction will go to table location A and from this location will replace the zero with the BCD blank character. Since the address part of location A contains A, the second table reference will begin at location A of the table. Once a non-zero digit occurs, the cro instruction will make a table reference at location A + K, where K is the non-zero digit. Location A + K contains K in positions S,1-5 and A + 10 in the address part. Thus, the value K will replace the number Kand this insures that the non-zero digits will be preserved. Once the first non-zero digit is found, only the second part of the table, location A + 10 through A + 19, is used. This insures that zeros following the first non-zero will be replaced with zeros instead of blanks. Figure 106 illustrates the execution of the convert instruction using the BCD number 000307.

When all six of the BCD digits have been tested (the count reduced to zero), the execution of the CRQ instruction is terminated. Since the instruction contains a tag of one, the address part of the last table reference location will be placed in index register 1. After

i	OUT				PROGRAM CONTINUES HERE					

Figure 105. Edit Program

storing the edited BCD number (STQ BCDI) the contents of index register 1 are then compared with the number A by the TXH OUT,1,A instruction. If the index register contains A, then all six of the high-order BCD digits were zero and the program will continue to examine the remaining digits in the number. If the index register contains A+10, this indicates that a non-zero digit was found in the high-order six digits. Thus, the low-order digits need not be processed and control is transferred to location out.

The convert instruction CVR can be used to perform BCD addition without having to rely on a complex logical routine. The CVR instruction is used in this application since it is necessary to process the decimal

sum from right to left to provide for carries from one position to the next. The program which will add two 6-digit unsigned BCD numbers is shown in Figure 107. This program insures that the following conditions are satisfied.

- 1. Any position of the sum that does not produce a carry must be preserved.
- 2. Any position of the sum that does produce a carry must be modified with the carry propagated to the next position.
- 3. A test must be made to determine whether or not a carry occurs out of the high-order position. If such a carry does occur, a one must be placed in the next highest word location.

Figure 108. Table for BCD Addition

The convert instruction cvR used in the program uses the table found in Figure 108.

The execution of this program can best be illustrated by the following example. The two BCD unsigned numbers 434589 and 691593 are to be added. The resulting sum is considered as six 6-bit numbers (Figure 109). The low-order 6-bit number has the value 12. Thus, the first table reference made by the CVR A,1,6 instruction is at location A + 12. Positions S,1-5 of this location contain a BCD 2 which replaces the number 12 in the AC. Positions 21-35 of this location contain the number A + 1. The address A + 1causes the next table reference to be made at location A + 18 rather than A + 17. Thus, a carry of one is propagated from the units to the tens position of the sum. The execution of the CVR will end when the count has been reduced to zero. Since this instruction has a tag of one, the contents of the storage register

positions 21-35 (A + 1) will be placed in index register 1. The TXL OUT,1,A instruction then tests the contents of this index register. Since A + 1 is greater than A, the program continues and a BCD 1 is placed in positions 30-35 of location SUM + 1. Had index register 1 contained A, the program would have transferred control to location OUT.

Conversion from one number system to another may be performed by the CAQ convert instruction. An example of BCD-to-binary conversion is illustrated here. The program which performs this conversion is based upon the fact that a BCD number (e.g., 803157) is really a sum of terms of the form:

$$8 \times 10^5 + 0 \times 10^4 + 3 \times 10^3 + 1 \times 10^2 + 5 \times 10 + 7.$$

The binary number equivalent to a BCD number is obtained simply by finding the sum of the binary equivalents of each term. For this example, the binary equivalent of 8×10^5 plus the binary equivalent of 0×10^4 plus . . . plus the binary equivalent of 7. The table used with this program is thus divided into six parts (Figure 110). Each section consists of ten words, one word for each of the digits 0.9 multiplied

by a power of ten. The binary equivalent of each BCD digit is contained in the twenty positions S-19 of each word in the table. This is based on the fact that only 20 binary positions are necessary to represent a 6-digit BCD number.

The CAQ instruction uses a straightforward table look-up operation to build up the binary equivalent of the BCD number, digit by digit. Each digit of the BCD number is employed to look up its binary equivalent from one of the six parts of the table. The first BCD digit will choose its binary equivalent from the first section (105) of the table; the second BCD digit will choose its equivalent from the second section of the table; and so forth. This operation is continued until the complete binary equivalent is formed in positions P-19 of the AC. Caution must be taken to choose table locations so that the sum of the locations (as illustrated in Figure 112) will not overflow into the resulting binary number portion of the AC.

The program in Figure 111 will perform the conversion operation.

The execution of the CAQ A,0,6 instruction is illustrated in Figure 112. As can be seen, the sum of the table locations B,C, . . .,F must not form a sum that will overflow into the binary portion of the Ac.

Sense Indicators

In many applications of data-processing machines it is desirable to have switches which can be set and tested by the program. A special register, the sense indicator register, provides 36 such devices. Each of these can be turned on or off (zero or one). The individual positions are called sense indicators.

Either singly or in groups these indicators can be turned on or set (set to ones) or turned off or reset (set to zeros). These indicators can be used as program-controlled sense switches, sense lights, or selectors. In addition, they are also useful in extracting or inserting parts of words and for testing fields within a word.

A program is often written that deals with a problem having several variations. In cases of this type,

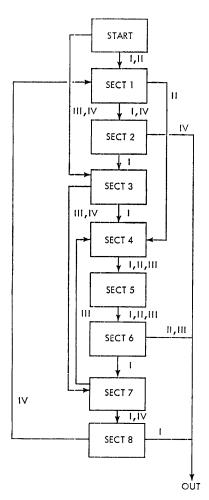

Figure 113. Block Diagram of General Program

one way of developing the general program is to construct the program so that it is composed of self-contained sections. Control in the general program is then transferred from section to section in the sequence determined by the particular variation being solved. The sense indicators may be used to direct and monitor the desired sequence of control.

For example, a general program is composed of eight sections and is to deal with a problem having four variations. The eight sections and the four variations are illustrated in Figure 113. The sequence of control necessary for each variation and the representation of the sense indicator bits needed for the direction of this sequence are shown in Figure 114.

	sequence of control			IDICA POSI	TOR TIONS
VARIATION	BY PROGRAM SECTION	32	33	34	35
I II III IV	1-2-3-4-5-6-7-8 1-4-5-6 3-7-4-5-6 3-7-8-1-2	0 0 0	0 0 1 0	0 1 0 0	1 0 0

Figure 114. Sense Indicator Pattern

Four control words are used to contain the different bit patterns to be used in the sense indicator register for the four different problem variations (Figure 115). The general program is started by loading the desired control word into the sense indicator register.

LOCATIONS	CONTROL WORD	REMARKS
VARI	Oct 1	Variation 1 bit pattern for the SI register
VARII	Oct 2	Variation 2 bit pattern for the SI register
VARIII	Oct 4	Variation 3 bit pattern for the SI register
VARIV	Oct 10	Variation 4 bit pattern for the SI register

Figure 115. Problem Variations

The instructions in the general program that are necessary for the direction of control are shown in Figure 116.

Both the RFT and RNT instructions contain masks (in octal) in positions 18-35. These 18 bits are compared with the right-most (positions 18-35) 18 bits of the sense indicator register. The instruction LFT and LNT with the same masks could have been used in place of the RFT and RNT instructions. However, since these instructions compare with the left-most

Figure 116. Control Instructions in Program

18 positions (positions 0-17) of the sense indicator register, the four commands must be changed so that the four si positions concerned are positions 14-17.

It may be necessary to unpack a word without affecting the accumulator or the multiplier-quotient

register. In this case, the sense indicator register may be used for the unpacking operation. For example, to unpack a number occupying positions 14-24 of a packed word, a mask containing ones in positions S,1-13,25-35 is used to perform the extraction.

Figure 117 is the program which is used to execute the extracting. The packed word is loaded into the stregister by the LDI instruction. With the execution of the RIS instruction all the positions in the street sponding to the ones in the mask are set to zero. Thus, as a result of the mask used, the desired number in positions 14-24 is left intact and the remaining positions are set to zero. The number extracted from the packed word is simply dependent on the mask used.

A companion operation to the extracting described above is that of insertion. This may also be accomplished by using the st register. An example is inserting a new number in positions 14-24 of the packed word of the last example. The new number to be inserted occupies positions 14-24 of the Ac. The program is shown in Figure 118. The packed word is loaded into the st by the LDI instruction. The mask used by the RIS instruction sets positions 14-24 of the st to zero. The remaining positions are unchanged. The new number is then "or'ed" into the packed word by the OAI instruction.

Floating Point Overflow and Underflow

During many scientific and engineering problems, the programmer is faced with the difficulty of keeping track of the decimal point. To aid in this respect, the computer is equipped with a complete set of floating point instructions. Briefly, a floating point number is treated as a 27-bit signed proper fraction and an

8-bit characteristic which represents a signed exponent.

By the nature of floating point operation, the fraction may never overflow the registers, and an underflow of the fraction produces a normal zero which is a proper result. The characteristic enjoys no such freedom. A floating point operation resulting in a characteristic, either too large or too small for that portion of the word set aside for it, produces a condition known as floating point overflow or underflow, respectively. These conditions are referred to collectively as floating point spill.

When floating point spill occurs, the factors must be scaled to fall within the range of the computer registers if calculation is to continue. The exact details of this scaling usually depend upon the conditions of the problem. However, the computer provides adequate facilities to assist the programmer in deciding what these conditions are and for controlling the corrective process.

The computer may be operated in two modes with regard to floating point operation. Normally, the computer operates in *floating point trap mode;* that is, the floating point trap device is normally on. This device is referred to as "FPT." If the instruction leave floating trap mode (LFTM) is executed, the computer operates in what is called the 704 floating point trap mode.

IBM 704 Floating Point Trap Mode

To enter the 704 floating point trap mode, the instruction LFTM must be executed. It is necessary be-

Figure 118. Insertion Program Using Sense Indicator

cause FPT is normal in the computer. If a floating point spill occurs while in the 704 mode, the accumulator and/or the MQ overflow indicators are turned on. Which indicator is set is determined by the register producing the spill. Each indicator may be tested by the program, subsequent to the spill, by executing the proper overflow test instruction. The mathematics involved in the following examples are specialized to point out how the logical facilities of the computer might be employed to detect and to control the correction of floating point spill.

Floating Point Spill in the 704 Mode

This problem is defined below.

A body of surface area (SURA) is being bombarded by particles of some nature. The researcher has measured the number of impacts (IMP) on the surface at N discreet time intervals. At a certain point in the calculations, the programmer wishes to know if the following conditions exist: Q < MAX, where MAX is a constant and q is the average number of impacts per unit area. If the inequality holds, the program is to continue at location ok. Otherwise, program control is to be transferred to symbolic location tobic.

All the IMP_n (total impacts in the N time intervals) are written within the range $0 \le IMP_n < 10^{45}$. The IMP_n are stored at symbolic locations IMP to IMP + N - 1. The values N, MAX, and SURA are known. The original values of IMP_n must remain intact. The first step is to calculate the total impacts. If a spill occurs, the IMP_n are scaled by 2-100, and the summation repeats. If another spill occurs, it is treated as an irretrievable error. Note that MQ spill has no effect on this summation. The program is shown in Figure 119 and executed as described below:

Line 1. LFTM must be given to enter the 704 mode. The accumulator overflow indicator is then turned off by the Tov instruction; this is necessary because its condition cannot be assumed.

Line 6. The IMP_n is brought to the accumulator. Because of the method of scaling used, zero words are skipped over.

Line 8. Because spill detection is most useful if the first spill is detected, scaling is accomplished without using floating point. If xra is zero, scaling is not required and the program proceeds to line 11. If xra is not zero, scaling is required. A word containing an octal 100 in the characteristic field is fixedpoint subtracted from the IMP_n. This is equivalent to floating point division by 2100. If the accumulator goes minus, the IMP_n is not within the given range. If IMP_n is not in this range, control is transferred to

Line 11. The partial sum is added to the IMP, in the accumulator. If spill does not occur, the program proceeds with the summation; if spill does occur, XRA is set to 1 and the summation is restarted. If scaling has already occurred, an error is indicated and control transfers to 2ERR.

Line 18. The MQ overflow and the divide check indicators are reset to the off position, because their condition cannot be assumed. The FDP is then exe cuted and both the divide check and mo overflow indicators are tested (MQ overflow or underflow is defined as a TOBIG condition).

Line 27. With the quotient in the accumulator and the condition of the accumulator overflow indicator established (lines 25 and 26), a test to find if scaling has taken place is executed. If so, the word subtracted in line 9 is added back to increase the characteristic by 100, which is equivalent to floating point multiplication by 2100. An overflow at this point (fixed point overflow) indicates that q is too big. If scaling has not occurred, control transfers.

Line 30. MAX is then subtracted from the quotient. A spill at this point is not significant; the sign of the result establishes the range of the number. If the accumulator is minus, the program proceeds to symbolic location ok, where FPT is reset to the on position and the main program may resume.

Floating Point Trap

Figure 119 illustrates how the interpretation of spill depends upon the conditions prevailing when the spill is detected. In general, the program should: (1) detect the spill as soon as it occurs, (2) know in which register the spill occurred, and (3) know what instruction was being executed when the spill occurred. This information can be provided automatically by the floating point trap.

When spill occurs with the FPT on, the computer automatically performs the following steps:

- 1. The address plus 1 of the instruction causing spill is placed in the address field of core location 0000.
- 2. A four-bit code which identifies the nature of the spill is placed in positions 14 through 17 of core location 0000.
- 3. The computer takes its next instruction from location 0010 and proceeds from there.

To illustrate a use of FPT, the problem used in Figure 119 is repeated using the floating-point-trap feature. Note that, although the program is larger, the possibilities for control are increased. Figure 120 shows that the trap routine starting at location 0010 can conditionally return to the main program or

initiate a general operation (in this case, a print program and then halt).

The practice of continually storing certain addresses from the main program in a standard routine is sometimes referred to as "breakpoint" programming; as Figure 120 shows, it is an extremely powerful and

Figure 120. Floating-Point Trap

flexible technique. Note the use made of the decrement bits at location 0000 and a use of the address field of location 0000 in the routine spil2.

Line 1. Location 0000 is cleared to erase any data that may have been placed in it by a previous routine. The symbolic address spill is placed in the xec instruction located at 0010. This causes the trap routine to return control to this program. Note: a postmortem print that prints location 0010 informs the programmer that his program has passed this point.

Line 16. The TXI instruction regains control of the program from the trap routine, and sets the scaling signal by placing a 1 in XRB. Recall that an MQ spill was not significant at this point; therefore, with the partial sum stored, the bit code in the decrement portion of location 0000 is checked. If position 17 has a 1 while positions 14, 15, and 16 have 0's, the summation is continued and XRB is set to zero (line 21).

Line 22. If scaling has already been in progress, a second spill is defined as an error.

Line 24. A new control address is placed at location 0010, because a spill in the following routines is to be treated in a different fashion. (Again, the address field of location 0010 can inform the programmer that this point of the program has been processed).

Line 35. Note that the accumulator overflow indicator is related to fixed-point operations only, when the FPT is on.

Line 44. The transfer instruction seizes control from the trap routine. The decision is made as follows:

1. If the spill occurred in the FSB instruction, the octal code in the decrement of location zero is less than 0010. Such a spill is not significant

- and a return to the routine is made by an indirectly addressed TRA instruction.
- 2. If the spill occurred in the accumulator alone (on fdp), the octal code in the decrement of location 0000 is not greater than 0012 and not less than or equal to 0011. Accumulator spill, alone, at the fdp instruction is not significant. With an MQ spill, the conditions just stated are not met; the program proceeds to tobic location (MQ overflow or underflow is defined as a tobic condition).

Writing a Format Track

Format track data organization in core storage is shown in Figure 121. The accompanying program listing shows all octal and symbolic notations with appropriate comments. The format track shown in Figure 121 is made up as follows:

- 1. Gap 1, home address 1 (HA1), and gap 2 are called the track identifier area and consist of 24 characters. They must be written with eight-bit mode characters. The remainder of the format track may be written with either six-bit or eight-bit mode characters, according to the requirements of the data track. Six-bit mode characters are used in Figure 121.
- 2. Home address 2 (HA2) and the X gap are called the home address area 2 and consist of 22 characters.
- 3. The record address (RA) and the Y gap are called the record address area 1 and consist of 22 characters. Record address area 2 consists of four characters of the data record (synchronization), a single character gap 3, and 11 characters after gap 3. The last 11 characters are automatically written by the 7631. The entire record address area equals 38 characters.

Write, Write Check, and Read on Disk Storage

Using the format written with the first program example, the following program listing shows the main program steps necessary to write, write check, and

then read a 466-word record (maximum) using access 0, module 1, track 0038, and record address 927601. Both this program listing and the previous one are intended to show sample usage of instructions, commands, and orders and neither program has actually been tested on an operating system.

IBM 7094 System Consoles

IBM 7151-2 Console Control Unit

This description of the IBM 7151-2 Console Control Unit (Figure 122) is in three sections: the first concerns indicator lights, the second concerns incandescent lamps (including the color of the lamp cover) and panel keys and switches, and the third concerns data channel indicator lights.

Indicator Lights

Instruction Counter. The instruction counter is 15 positions long and is used to tell the computer the location of the next instruction to be performed. The instruction counter (IC) may be reset to zero at the start of the program or may be set to a predetermined address. Once the program is started, the IC counts sequentially unless a transfer instruction is executed. In this case, the IC is set to the address specified by the transfer instruction and is again stepped sequentially starting with this new address. The highest location in core storage and location zero are treated as consecutive addresses.

The IC is normally advanced at the end of the I cycle. However, some instructions cause the computer to skip one or two instructions and, therefore, the IC may be advanced as many as three times while the instruction is being completed. If a halt occurs during the execution of a divide or halt instruction or a halt and proceed instruction, the 1c has the address of the instruction being executed plus one. On execution of a halt and transfer instruction, the 1c contains the address of the instruction.

If the auto-manual switch is pressed during the execution of a CPU program, the IC contains the address of the instruction to be executed, plus one.

Instruction Register. Instructions and data are both in the form of 36-bit words, and the computer finds the difference between the two as follows:

- 1. Any word brought into the computer during an I cycle is treated as an instruction.
- 2. A word brought in at any other time is treated as data.

The instruction register (IR) is divided into two parts: positions S, 1-9 contain the operation part of the instruction; positions 10-17 form a counter called the "shift counter." In shifting, multiplication, and division instructions, the number of shifts to be made is placed in this counter.

With an 1-0 instruction, the address part of the instruction is placed into the shift counter. The counter

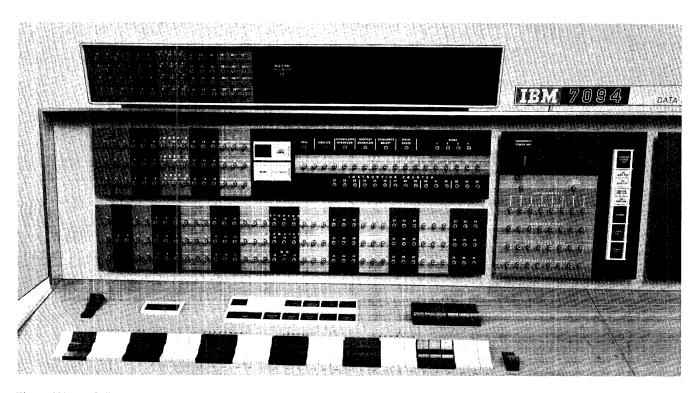

Figure 122. IBM 7151-2 Console Control Unit

in turn sets the class and unit selectors for the type of instruction (such as read, write, and so forth) and the exact unit involved.

Internal Registers. The contents of the internal registers (storage, accumulator, and MQ) are displayed on the console. The display is marked off in groups of three, making the direct conversion from binary notation to octal a matter of sight.

Index Registers. Seven rows of lights display the contents of the index registers.

Multiple Tag Mode. The multiple tag mode light (MT MODE) is turned on when the computer is operating in 7090 multiple tag mode.

Trap. The trap light goes on whenever the CPU is operating in the transfer trap mode.

Simulate. The simulate light is turned on when the 7094 is operating in the following modes associated with the 704-709 compatibility feature:

Input-output select and sense trap mode Copy and load drum address trap mode Storage nullify mode

Accumulator Overflow. This light is turned on at any time (during fixed point operation or shifting operations) when a carry out of position 1 of the accumulator occurs. It may be turned off by the TNO or TOV instructions.

Quotient Overflow. This light is on whenever an MQ overflow occurs and the computer is using the compatibility program.

Read-Write Select. The read-write select light is turned on when an input-output unit has been selected for reading or writing. The light goes off when the input-output unit is disconnected.

Divide Check. The divide check light is turned on (fixed-point division) if the dividend (accumulator) is greater than or equal to the divisor (storage). On a floating-point division, a divide check occurs if the divisor is zero or if the magnitude of the fraction of the dividend is greater than or equal to twice the magnitude of the fraction of the divisor. The divide check indicator is tested by the DCT instruction.

Sense. These four sense lights may be turned on, turned off, or tested through use of the proper plus or minus sense instructions.

Trap Control. This light is on when the channels are not executing a channel trap. It is off when any channel enters a trap condition. While the light is off, no channel traps may be executed. Channel traps may be executed only when the light is on at the same time as any of the command trap or channel tape check lights are on.

Channel Select. These lights (eight, one for each channel) are turned on according to the channel that is in operation. They are turned off if the channel is not in operation.

NOTE: Both the tape check and the channel select lights are duplicated on the data channel console.

Command Trap. These lights indicate which data channel is enabled for a trap on command or end-offile conditions. The lights are turned off when the channels are disabled.

Tape Check Trap. These lights indicate which data channel is enabled to trap on a tape check. The lights are off when the channels are disabled.

Channel Tape Check. These lights indicate a tape error during writing or if both the high and low check registers are in error while reading. The lights may be turned off by execution of a transfer on redundancy check instruction.

Incandescent Lamps

Program Stop (Red). This lamp is turned on when the computer executes a halt instruction.

I-O Check (White). The 1-0 check lamp is turned on by any of the following conditions:

- 1. If a reset or load channel instruction is executed and the specified channel has not been selected.
- 2. If, during writing, a data channel data register has not been loaded with a word from storage by the time its contents are to be sent to the output unit.
- 3. If, during reading, a data channel data register has not transmitted its contents to core storage by the time new information is to be loaded into it from an input unit.

Ready (White). This lamp indicates that all computer power circuits are at operating level and remains on except when the computer is in automatic status.

Automatic (Yellow). This lamp is on whenever the computer is executing instructions in the automatic mode or whenever a data channel is in operation.

Console Power On (Red). This lamp is on whenever power is applied to the console.

Computer Components Power Check (Yellow). This lamp is on whenever a fuse or circuit breaker is actuated in the central processing unit, multiplexor, or core storage. It also lights when core storage has improper oil temperature or low oil pressure.

I-O Power Check (Yellow). The 1-0 power check lamp is turned on whenever a fuse or circuit breaker

is actuated in a data channel or a fuse in card equipment is blown. A power failure in a data channel or its attached card equipment does not light this lamp if a data channel is switched off-line for testing.

Power (Red). This lamp is turned on whenever power is applied to the entire 7094 system.

Panel Keys and Switches

Auto-Manual Switch. Pressing this switch down stops the computer after it has completed the execution of the instruction then being processed, unless an 1-0 unit is connected to the logical unit. In this case, the computer stops after the 1-0 unit in use has been disconnected. The automatic light goes out, and all of the switches and the following keys become effective: display sense indicators, enter MQ, enter instruction, display effective address, multiple step, and single step. The clear key and load key become ineffective.

Clear Key. When the computer is in automatic status, pressing the clear key sets all magnetic cores to zero. In addition, all registers and indicators are reset as with the reset key depression. The clear key is inoperative when the computer is in true manual status.

Reset Key. Pressing the reset key resets all registers and indicators, except the si, in the logical section of the computer. That is, the si, AC, MQ, instruction location counter, instruction register, and index registers are set to zero and all indicators are turned off. All panel lights, except power and ready, are turned off. Core storage is not affected by the reset key. Any channels in automatic status and their associated registers are also reset.

Display Indicators. This key, when pressed, allows the true value of the sense indicators to be displayed in the storage register indicator lights.

Display Effective Address Key. Assume that the computer is in manual status, an instruction is in the SR, and the display effective address key is pressed. The difference between the contents of the address field in the SR and those of the index register tagged in that instruction (if one is tagged) will appear in the address field of the SR, where it may be read from the SR lights.

Load Keys. The load keys let the operator initiate the loading of a self-loading program stored on binary cards or a tape. If a self-loading program is stored on the tape whose logical identification is 221 and is attached to channel A, pressing the load-tape key causes the computer to perform the following sequence of instructions:

Read select channel A for tape unit 221.

Reset load channel A with a bit in position S, a word count of 3, and an address of 0000. (The first three words are sent to core storage.)

Send the contents of location zero to channel A as a command.

Transfer to core storage location 0001.

This sequence of instructions starts the loading of a program stored on tape 221.

Pressing the load card key causes the same sequence of instructions to be executed, except that the address in the first instruction is 321, selecting the reader instead of the tape unit.

When loading is started, it is essential that the input unit from which information is to be loaded into storage be in ready status. Pressing the load keys resets the channels. Note that the MQ register is not reset. The keys are operative only when the automanual switch is in automatic and the 7094 is in a ready status.

Start Key. Pressing the start key continues calculation at high speed if the computer has halted at a program stop or if it has been returned to automatic operation after having been in manual status. Pressing the start key resets the program stop light, and calculation starts with the operation specified in the instruction counter. Pressing the start key (CPU in manual) resets the program stop or 1-0 check light. All register contents are not destroyed. An index register may then be displayed or the program may be stepped at slow speed.

Single Step and Multiple Step Keys. These keys enable the operator, when the 7094 is in manual status, to proceed with his program either step-by-step (one step at a time) or at a slow automatic rate of speed. If an instruction that causes an input-output device to be connected to the computer is executed, the computer operates in the automatic mode until the 1-0 unit is disconnected. When this occurs, the computer returns to the manual mode.

With the 7094 II, an operation initiated by either single or multiple step keys continues in automatic until instruction overlap is not possible. The system will return to the normal mode. Instruction overlap may be inhibited by means of a console key, providing operation only in manual mode.

Enter MQ Key. If the operator manually keys a given word of information into the panel input keys and, if the enter-MQ key is pressed while the computer is in manual status, the keyed-in word replaces the contents of the MQ. The contents of the SR are destroyed by this operation.

Enter Instruction Key. If the operator presses the enter instruction key while the computer is in manual status, the word in the keys is executed.

With the 7094 II, all instructions are executed normally with the exception of skip instructions. When executed with the enter instruction key, skip instructions will not alter the contents of the instruction counter.

Display Storage Key. If, while the computer is in manual status, the operator keys a storage location into the address part of the panel entry keys and presses the display storage key, the contents of the address appearing in the keys are displayed in the sk where they may be read from the sk lights. In storage nullify mode, only the portion of storage not nullified may be displayed.

Sense Switches. Six sense switches give the operator manual control over the program while it is being executed by the computer at high speed. At various points in the program, giving sense instructions with the addresses of the sense switches causes the computer to follow one of two courses, depending on whether the sense switch tested is depressed. The sense switches are also effective while the computer is in manual status.

Panel Input Switches. These 36 panel input switches enable the operator to insert a word of information into the MQ or the instruction registers of the computer if it is in manual status and the enter-MQ or enter-instruction key is depressed. When a panel input switch is down, it represents "1"; when up, it represents a "0". (A bit configuration may be set in these keys and, with the computer in automatic mode, an ENK instruction will set the input switches' contents into the MQ.)

Reset Switch. This switch causes all panel input switches to be reset to the off or zero position.

Emergency Power Off. This is a pull-type switch that should only be used in an emergency, such as fire or excessive water.

IBM 7617 Data Channel Console

As with the operator's console, the data channel console has all registers, counters, and associated indicators of the data channel displayed on its console. In addition, input-output selection, operation, and several special indicators are included (Figure 123). The keys and lights above the dotted line on Figure 123 are customer engineering aids.

Indicator Lights

Data Register. These lights show the contents of the data register.

Word Counter. The word count minus one is indicated with these lights.

Address Counter. The core storage address is indicated with these lights.

Location Counter. These lights contain the address of the core storage location of the next command to be executed.

I-O Check. This light turn on for lack of a storage reference cycle on one-channel operation.

Tape Check. This light is turned on if any error is detected during reading or writing on tape. The channel tape check indicator light parallels the tape check light on the 7151-2 Console Control Unit.

End of Tape. The end-of-tape light is turned on during a write operation whenever the end-of-tape reflective spot of the selected tape passes the read-write head.

Beginning of Tape. This light is turned on whenever a backspace record or backspace file instruction moves a tape to its load point or attempts to backspace it beyond its load point.

End of File. When a disconnect occurs because an end of file is sensed during reading cards or tape, this light is turned on.

Word Count Equal to Zero. This light is turned on whenever the word count equals zero.

Read Gate, Write Gate, Data Register Loaded. These three lights are customer engineering aids.

Input-Output Indicators: Read Tape, Write Tape, BCD, WEOF, Rewind, Backspace Record, and Backspace File. These lights are turned on whenever the individual operations are being executed or stacked in the channel.

Unit Select. In automatic operation, these lights indicate which I-O unit is selected. Under manual conditions, they will reflect the setting of the unit select switch.

Operation Register. These lights reflect the operation part of the command being executed by the data channel. They pertain to the type of data transmission as follows:

- Sign (S) position: Data transmission under count control
- One (1) position: Data transmission under record control
- Two (2) position: Data transmission under transfer control
- Nineteen (19) position: Data transmission inhibited under read control
- Eighteen (18) position: Controls indirect addressing of all commands

Read Card Reader, Write Printer, Write Punch, Read Printer, Print Binary. One of these lights is turned on whenever a card machine is being used.

LRCR Register. These lights reflect the contents of the longitudinal redundancy register. They hold the

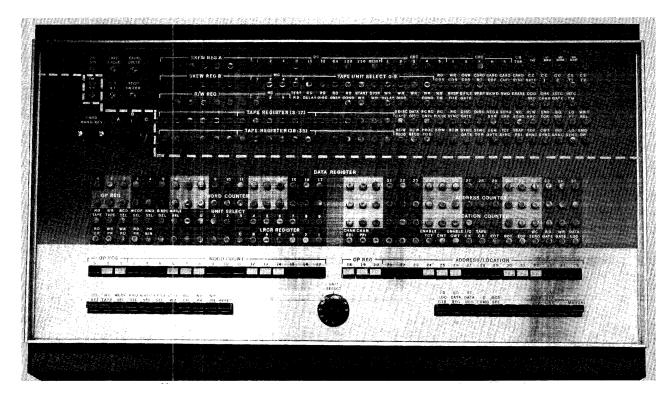

Figure 123. Operating Keys and Lights for IBM 7617

contents of the transmitted character between the disconnect and reselection of tape control circuits.

Channel Select. This light is on whenever the channel is in operation.

Channel Priority. This light is on whenever the channel has priority.

Enable Tape Check Trap. This light is on whenever an enable instruction is executed for this channel.

Command Word Trap. This light is on whenever a command word trap is being or is waiting to be executed.

Enable Command Word Trap. This light is on whenever an enable instruction is executed for this channel.

Keys and Switches

Entry Keys. There are 36 entry keys, one for each position of the 7094 word. When a key is depressed, it remains in the position until reset by the reset key for the entry keys. These keys are operative only when the channel is in manual status.

Write Punch, Write Printer, Read Tape, Write Tape, Read Reader. These keys control some phase of input-output operation when a channel is in manual status. They are inoperative if the channel is in automatic status. They are explained as a group because their operation is identical except for class of operation. One example of their use is in punching a card:

- 1. The auto-manual switch for channel A is in manual.
- 2. A command with a count of 24 (keys 13 and 14) and an address of 100 (keys 29, 30, and 33) is set up in the channel entry keys.
- 3. The load control key of the channel is depressed, entering the command set up in step 2.
 - 4. The write-punch key is depressed.

These steps would result in writing 24 words from core storage, starting at core location 100. On completion of the punching operation, the last word transmitted to the punch would be retained in the data register, the word count would be reduced to zero, and the address register would have advanced once for each word that was punched.

In another example, reading a tape, the sequence of operations would be the same as those in the first example for steps 1, 2, and 3. Step 4 would change in three ways:

The tape select switch for the appropriate channel would be set to the tape unit desired.

The mode, BCD or binary, would be set by use of the BCD switch.

The rest of the operation would be the same as example 1 except that the first 24 words on the selected tape unit would be stored in locations 100 through 123.

Rewind, Write End-of-File, Backspace Record, Backspace File. These keys are also grouped because their operation is the same except that they refer to the non-data type of operation and are concerned only with tape. Depending on the setting of the select switch, the specified tape unit would, according to which key was depressed, rewind, write an end-of-file, backspace one record, or backspace one file.

Stop Write. This switch is effective only if the channel is in manual status. It is primarily a service aid and is used with the write tape switch to interrupt write tape operations.

Reset Key. This key is operative only if the manual switch is in manual. Depressing the reset key resets all indicators, registers, and counters that are under manual control.

Load Location Counter. Depressing this key causes the information set up in the channel entry keys (21-35) to be entered into the location counter.

Load Data Register. Depression of this key sets the condition of the entry keys into the data register of a channel in manual status. The key has no effect if channels are in automatic.

Store Data Register. This key, when depressed, causes the contents of the data register, for a channel in manual status, to be stored in core storage at the address in the address register of the channel. After the word is stored, the address register is increased by one and the word count register is decreased by one. When channels are in automatic, this key is inoperative.

Load Command. This key, when pressed, causes information set up on the channel entry keys to be entered into the indicators, word counter, and address register of whichever channel is in manual status. Entry keys, S, 1, 2, 18 and 19 are entered into the indicators, keys 3-17 are sent to the word counter, and keys 21-35 are sent to the address register.

BCD. The BCD switch is operative only in manual status and, when pressed, forces a BCD mode of operation.

Display Storage. Pressing this key causes the contents of the storage location whose address appears in

the channel's address register to be displayed in the data register of a channel in manual status. The key is inoperative if channels are in automatic status.

Note: If either the store data register or the display storage key is depressed more than one time: for each depression the next sequential storage location will either receive the contents of the data register or be displayed in the data register.

On-Off Line. This switch is effective only if the channel is in manual status. When the switch is in ON-LINE position, data may be transmitted to or from storage. When the switch is in OFF-LINE position, data cannot be sent to or from storage. When the channel is writing in the OFF-LINE position, the contents of the data register are repeatedly written.

Manual. In AUTOMATIC position, this switch permits normal channel operation. In MANUAL position, this switch activates the other manual controls and entry keys. With this switch in the MANUAL position, the following instructions will be affected as indicated:

Transfer on channel in operation will not transfer. Transfer on channel not in operation will transfer.

Transfer on channel EOF will not transfer.

Transfer on channel redundancy-check will not transfer.

Store channel probably will store zeros, but may store any combination of zeros and ones.

The execution of any of the following instructions will result in "hanging up" the CPU:

Load channel or reset and load channel

Read channel or write channel

Rewind channel or write end-of-file channel

Backspace record channel or backspace file channel

If either sense-printer or sense-punch instruction is executed, it will be treated as no-operation. With the execution of either beginning-of-tape-test or end-oftape-test, the program will skip the next instruction and then proceed.

An enable instruction that is not completely executed can cause the loss of a channel trap. Incomplete execution can occur if the 7617 Console is in "manual" status when the CPU is processing an enable instruction to the associated 7607 Data Channel.

Unit Select. The positions of this rotary switch, numbered 1 through 10, control unit selection under manual status. Assume that the select switch is turned to position 3 with the channel in manual status. Any tape unit attached to that channel whose individual select switch is set at '3 will be selected for manual operation under the control of the channel tape control keys.

In addition to its tape function, the switch is active when a printer or punch select key is depressed to activate the corresponding sense exit on the printer or punch control panel. If no sense exit is to be set, the switch must be set to an unlabeled position.

Tape Density Option Switch. This three-position switch controls the pair of densities at which a given tape unit operates. Program instructions or the change-density switch on the tape unit itself specify either low-density or high-density recording. With the switch in position A, tape units attached to the tape channel operate in a density of either 556 or 800 characters per inch. With the switch in position B, the recording density is 200 or 800 characters per inch. With position C, the density is 200 or 556 characters per inch.

Print Binary (PR BIN)/Tape Word Incomplete (TWI). This switch is a dual-purpose switch, depending on its position.

- 1. When operated in the PR BIN position, this switch causes the printer to print a 1 for each 1 bit and leave a blank for each 0 bit of the core storage locations addressed. The PR BIN switch is used with the write printer key for on-line test.
- 2. When operated in the TWI position, this switch is used to detect incomplete binary words (of other than multiples of six characters). Incomplete tape word detection results in redundancy check indications and only when operating in the binary mode.

IBM 7151-2 Operations

Entering Information

Information may be entered into core storage from the IBM 7151-2 Console Control Unit. The sequence of operations necessary to enter a constant or new information is as follows (assume that the instruction clear and add 0100 is to be inserted into storage):

- 1. With the auto-manual switch in the MANUAL position, set the bit configuration for the instruction (0500...0100) into the panel entry keys (switch down equals 1, switch up equals 0).
- 2. Depress the enter MQ key to store the contents of the entry keys into the MQ register.
- 3. Now place the bit configuration for the store MQ instruction (-0600...xxxx) into the keys. The xxxx or address portion may be any storage location (assume 0200). If the enter instruction key is now depressed, the contents of the MQ register (CLA...0100) are stored at core location 0200.

Load Key Operation

The load keys let the operator initiate the loading of a self-loading program stored on binary cards or a magnetic tape. If a self-loading program is stored on the tape whose logical identification is 0221, and is attached to data channel A, pressing the load tape key causes the computer to perform the following sequence of instructions (auto-manual switch must be in AUTO position):

- 1. Read select channel A for tape unit 221.
- 2. Reset load channel A with a bit in position S, a word count of 3, and an address of 0000 (first three words are sent to core storage).
- 3. Send the contents of location zero to channel A as an input-output command.
- 4. Program transfer to location 0001 for an instruction.

This sequence of instructions and operations starts the loading of a program stored on magnetic tape unit 221.

Pressing the load card key causes the same sequence of instructions to be executed, except that the address of the read select instruction is 0321, which selects the card reader attached to channel A, instead of the tape unit.

When loading is started, it is essential that the input unit to be used be in ready status. Pressing the load keys automatically resets channel registers. Note that the MQ register is not reset and load keys are operative only if the console is in automatic status (auto-manual switch in AUTO and the 7094 in a ready status).

IBM 7617 Console Operations

Several operations may be performed from the data channel console when the console is in a manual mode (manual switch depressed). These include:

- 1. Data transmission operations
- 2. Non-data tape operations
- 3. Loading operations
- 4. Storing operations

Data Transmission Operations

Five different types of data transmission operations include: write printer, write punch, write tape, read cards, and read tape. Pressing of any of these keys initiates read or write operations. For tape operations, the tape unit selected is specified by the data channel

console unit select switch. The unit selected for transmission must be in a ready condition, and an input-output command must be loaded into the data channel registers before pressing any data transmission key. Assume that information contained in core storage locations 5000 through 5100 is to be written on tape unit 1 attached to data channel A. The following steps would be taken:

- 1. Place the auto-manual switch in MANUAL.
- 2. Set the bit configuration for an IOCD command with a word count of 77 and a starting address of 5000 (0 00077 0 05000).
 - 3. Press the load command key.
 - 4. Turn the unit select switch to its 1 position.
- 5. Press the write tape key. With the BCD switch depressed, tape will be written in the BCD mode; in its normal position, a binary tape will be written (assuming one of the tape units attached to that channel has its selector switch set at 1 and that the tape unit is in a ready status).

Other types of data transmission may be accomplished by depressing a different transmission key in step 5.

The on-off line switch is effective only when the channel is in manual status. When the switch is in on-line position, data may be transmitted to or from storage concurrently with computing. When the switch is in off-line position, data cannot be sent to or from storage but the contents of the data register may be repeatedly written. The word counter does not operate with this switch in the off-line position.

Non-Data Tape Operations

Four non-data tape operations may be performed:

- 1. Backspace record
- 2. Backspace file
- 3. Write end-of-file
- 4. Rewind

When one of these keys is depressed, the operation is performed on the tape unit selected by the channel console select switch. As with data transmission operations, the unit selected must be in ready status or the operation will not occur, and the particular light (backspace record, write end-of-file, and so on) will remain on signifying that the operation has not been completed. If it is impossible for the operation to occur (i.e., backspacing a tape unit beyond its load point), the data channel completely ignores the operation and the light is not turned on.

Loading Operations

Three loading operations may be performed from the data channel console:

- 1. Load data register
- 2. Load command
- 3. Load location counter

Pressing the load data register key places the contents of the data channel entry keys (S, 1-35) into the data channel data register. The load command key loads the contents of the data channel console entry keys into the: operation register (keys S, 1, 2, 18 and 19), word counter register (keys 3-17) and channel address register (keys 21-35). If, after a command is loaded, a data transmission key is depressed, the channel performs any function not involving the central processing unit. For example, input-output proceed type commands will function, but load channel or channel trap operations will not. If a load data register operation precedes a load command operation, the data in the data register will be destroyed.

Indirectly addressed commands cannot be loaded when the data channel is in a manual mode, because indicator 18 is recognized only when it is brought from storage. This is true also of the transfer in channel command. An indirectly addressed command in storage may be referred to with the data channel in a manual mode and will then be processed in the normal manner.

The load location counter operation takes the contents of the data channel entry keys and places them in the corresponding positions of the location counter whenever the load location counter key is depressed.

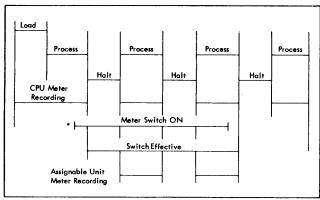

When the display storage key is depressed, the contents of the core location specified by the channel address register are displayed in the data register lights. With each depression, the contents of the word counter and channel address register are increased by one, accomplishing sequential core location displays. This key provides the ability to display storage concurrently with computing.

Storing Operations

Pressing the store data register key stores the contents of the data register at an address in core storage specified by the channel address register. Again, the word counter and channel address register are increased by one, allowing sequential storing operations with successive depressions of the store data register key. Storing occurs concurrently with computing.

System Reaction and Recovery Techniques — Metered Machines

An IBM data processing system consists of a CPU cluster, assignable units, and I/O units. The customer usage meter on assignable units (control units, channels, files, and drums) is controlled by an enable switch. This switch is effective only during a CPU halt condition (see Figure 124) and should be on when the program is started. If the enable (meter) switch is off, the assign-

The chart indicates that it is not mandatory for the meter switch to be on before starting the program. If a program halt precedes the program selection of the assignable unit, the meter switch may be turned on any time prior to or during the halt.

Figure 124. Meter (Enable) Switch Operation

able unit and any attached 1/0 units are disabled, and the CPU hangs up when the program selects a disabled unit. The following procedure may be used to recover from such a condition:

SYSTEM REACTION

The system hangs up in automatic status.

RECOVERY TECHNIQUE

Stop the system, turn on the meter switch, and restart the system.

Note: "Restart the system" means that the same precautions should be taken as in recovering from a CPU hangup due to any other cause.

Exceptions to the hang-up condition:

1. If a 7909, with no interrupt, programs a 7631 or 7640 whose meter switch is off, the 7909 interrupts with an adapter check. This allows transfer to a subroutine and a programmed option to halt the system.

Note: A 7909 hangs up if it is already interrupted. The CPU can then: (1) Hang up in a busy loop. (2) Be in a CPU hangup condition if the program selected the channel.

2. If a 7631 selects a 1301, 1302 or 7320 whose meter switch is off, an unusual end condition occurs.

Stop the system, turn on the 7631 or 7640 meter switch, and restart the system.

Perform a sense operation to determine which disk unit has the meter switch off. Halt the CPU, turn on the disk unit meter switch, and restart the system.

Appendix

A. Number Systems and Conversion

The common decimal notation of the commercial and scientific world is familiar to all of us. This notation is so familiar that you probably have never before questioned its use. Could it be possible that, for some purposes, another system is more convenient? The decision is entirely a matter of convenience. Decimal notation is used because it is most familiar and is understood by most people. However, had our primeval ancestors developed eight fingers instead of ten we would probably be more familiar with the octal system and would be questioning the decimal system.

The decimal system, with its ten digits, is learned by most people early in their training. This system serves very well for counting purposes. Why then, should computers which are designed to assist mathematicians, or engineers and businessmen, be designed to use the binary system of numbers?

Current digital computers use binary circuits and the mathematics of the computers is therefore binary in nature. The only convenient way to learn the operation of a computer is to learn the binary system. The octonary or octal system is a shorthand method of writing long binary numbers. Octal notation is used when discussing the computer but has no relation to the internal computer circuits.

Perhaps, as a first step, it would be well to see what is meant by the binary system of numbers. The binary, or base-two system, uses two symbols, 0 and 1, to represent all quantities. Counting is started in the binary system in the same manner as in the decimal system with 0 for zero and 1 for one. At two in the binary system it is found that there are no more symbols to be used. It is therefore necessary to take the same move at two in the binary system that is taken at ten in the decimal system. This move is to place a 1 in the next position to the left and start again with a 0 in the original position. A binary 10 is equivalent in this respect to a 2 in the decimal system. Counting is continued in an analogous manner with a carry to the next higher order every time a two is reached instead of every time a ten is reached. Counting in the binary system is as follows:

BINARY	DECIMAL	BINARY	DECIMAL
0	0	101	5
1	1	110	6
10	2	111	7
11	3	1000	8
100	4	1001	9

The binary system is used in computers because all present components are inherently binary. That is, a relay maintains its contacts either closed or open, magnetic materials are utilized by magnetizing them in one direction or the other, a vacuum tube is conveniently maintained either fully conducting or nonconducting, or the transmission of information along a wire may be accomplished by transmitting or not transmitting an electrical pulse at a certain time.

Although binary numbers in general have more terms than their decimal counterparts (about 3.3 times as many), computation in the binary system is quite simple.

For addition, it is only necessary to remember the following three rules:

- 1. Zero plus zero equals zero.
- 2. Zero plus one equals one.
- 3. One plus one equals zero with a carry of one to the next position on the left.

To see how the rules work, consider the addition of 15 plus 7 with these numbers expressed in binary notation:

	SIXTEENS	EIGHTS	FOURS	TWOS	ONES
(carries)	(1)	(1)	(1)	(1)	
	0	1	1	1	1 = 15
	+ 0	0	1	1	1 = 7
•	1	n	1	1	0 - 22

In the ones column we have 1 plus 1 for a sum of 0 and a 1 carried to the two column. In the twos column we have 1 plus 1 for a sum of 0 but we must also add the carry from the ones column, making a final sum of 1 with a carry to the fours column. The same procedure occurs in the fours column. In the eights column we have a 1 plus a 0 giving a sum of 1, but adding in the carry from the fours column makes the final sum 0 with a carry to the sixteens column. In this column we have 0 plus 0 giving a sum of 0 and to this we add the carry from the eights column, making a final sum of 1.

The resultant sum of the addition contains 1's in the sixteens, fours, and twos columns, which is the binary representation of 22, the correct sum of 15 plus 7 (16 plus 4 plus 2 equals 22).

The rules for *subtraction* of binary digits are equally simple:

- 1. Zero minus zero equals zero.
- 2. One minus one equals zero.

- 3. One minus zero equals one.
- 4. Zero minus one equals one, with one borrowed from the left.

Using the same numbers as we did in the addition, the subtraction works as follows:

	SIXTEENS	EIGHTS	FOURS	TWOS	ONES
(borrows)	0	0	0	0	0
	0	1	1	1	1 = 15
	- 0	0	1	1	1 = 7
	0	1	0	0	0 = 8

In the ones column we have 1 minus 1 for a sum of 0 with no borrows. The same procedure occurs in the twos and fours columns. In the eights column we have 1 minus 0 for a sum of 1. In the sixteens column we have 0 minus 0 for a sum of 0. With the subtraction finished we have 1's in the eights column only, signifying the answer to be 8.

For *multiplication* only three rules need to be remembered:

- 1. Zero times zero equals zero.
- 2. Zero times one equals zero; no carries are considered.
- 3. One times one equals one.

The binary multiplication table is such that all that is necessary when multiplying one number (multiplicand) by another (multiplier) is to examine the multiplier digits one at a time and, each time a 1 is found, add the multiplicand into the result, and each time a 0 is found add nothing. Of course, the multiplicand must be shifted for each multiplier digit, but this is not different from the shifting that is done in the decimal system.

An example of binary multiplication is 26 multiplied by 19:

DE	CIMA	AL											BINARY
	26	=	16	+	8	+	0	+	2	+	0	=	11010
X	19	=	16	+	0	+	0	+	2	+	1	==	10011
			the a							uct			11010
			arri										11010
			ing t					ıd					00000
	and	l sh	iftin	g wl	hen	evei	•					0	0000
	a l	is f	oun	d in	th	e						11	010
	mu	ltip	lier.									11	1101110

Interpreting the binary result of the multiplication by using the ones, twos, fours, . . . etc., system we find that we have,

$$256 + 128 + 64 + 32 + 0 + 8 + 4 + 2 + 0$$

which equals 494, thus proving the problem.

Binary division is accomplished by applying similar concepts. From the examples of addition, subtraction,

and multiplication, it may be seen that whatever operation the computer is working on will be accomplished by repetitive addition.

The computer operates internally using the binary system. However, it is able to convert from one system to another by use of a stored program. Thus, input-output data may be expressed in decimal (or any other) form when the operator finds it more convenient to do so.

Octal Number System

It has already been pointed out that binary numbers require about three times as many positions as decimal numbers to express the equivalent number. This is not much of a problem to the computer itself. However, in talking and writing, these binary numbers are bulky. A long string of ones and zeros cannot be effectively transmitted from one individual to another. Some shorthand method is necessary. The octal number system fills this need. Because of its simple relationship to binary, numbers can be converted from one system to another by inspection. The base or radix of the octal system is 8. This means there are eight symbols: 0, 1, 2, 3, 4, 5, 6, and 7. There are no 8's or 9's in this number system. The important relationship to remember is that three binary positions are equivalent to one octal position. The following table is used constantly when working on or about the computer.

BINARY	OCTAI
000	0
001	1
010	2
011	3
100	4
101	5
110	6
111	7

At this point a carry to the next higher position of the number is necessary, since all eight symbols have been used.

BINARY		OCTAI
001 000		10
001 001		11
001 010		12
001 011		13
001 100		14
	and so on.	

Remember that as far as the internal circuitry of the computer is concerned it only understands binary

ones and zeros. The octal system is used to provide a shorthand method of reading and writing binary numbers.

Number Conversions

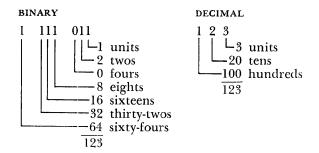

Before an attempt is made to convert numbers from one system to another, it is best to review what a number represents. In the demical system a number is represented or expressed by a sum of terms. Each individual term consists of a product of a power of ten and some integer from 0 to 9. For example, the number 123 means 100 plus 20 plus 3. This may also be expressed as:

$$(1 \times 10^2) + (2 \times 10^1) + (3 \times 10^0)$$

Ten is said to be the base or radix of this system because of the role that the powers of 10 and the integers up to 10 play in the above expansion. If two is chosen as the base, numbers are said to be represented in the binary system. Consider the binary number 1 111 011. What do these zeros and ones represent? They represent the coefficients of the ascending powers of 2. Expressed in another way the number is:

$$(1 \times 2^6) + (1 \times 2^5) + (1 \times 2^4) + (1 \times 2^3) + (0 \times 2^2) + (1 \times 2^1) + (1 \times 2^0)$$

The various orders do not have the meaning of units, tens, hundreds, thousands, etc., as in the decimal system; instead they signify units, twos, fours, eights, sixteens, etc. In applying the above information it is found that the number 123 breaks down in both systems as follows:

In the octal system, a number is represented in the same manner except that the base is 8. The digits of the number represent the coefficients of the ascending powers of 8. Consider the octal number:

$$173 = (1 \times 8^{2}) + (7 \times 8^{1}) + (3 \times 8^{0})$$

$$= 64 + 56 + 3$$

$$= 123 \text{ (decimal)}$$

Similarly:

By remembering what a number represents in the binary or octal system, the number can be converted to its decimal equivalent by the method shown above. As the numbers get bigger, this method becomes quite impossible to use. The following section provides detailed methods for converting from one system to another.

Integers

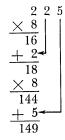

DECIMAL TO OCTAL

Convert the decimal number 149 to its octal equivalent. Rule: Divide the decimal number by 8 and develop the octal number as per example.

We first divided the original number to be converted by 8. The remainder of this first division becomes the low-order digit of the conversion (5). We then divide the quotient (received from the first division) by 8. Again the remainder becomes a part of the answer (next higher order, 2). This is continued until the quotient is smaller than the divisor. At this time the final quotient is considered the high order of the conversion (2).

OCTAL TO DECIMAL

Convert the octal number 225 to its decimal equivalent. Rule: Multiply by 8 and add, as per example.

The high-order digit is multiplied by 8 and the next lower-order digit is added to the result. The resultant answer is then multiplied by 8 and the next lower-order digit is added to the result. When the low-order digit has been added to the answer, the process ends. In the following examples, where multiplication or division is used, detailed explanations will not be used because the operations are similar.

OCTAL TO BINARY AND BINARY TO OCTAL

RULE: Express the number in binary groups of three.

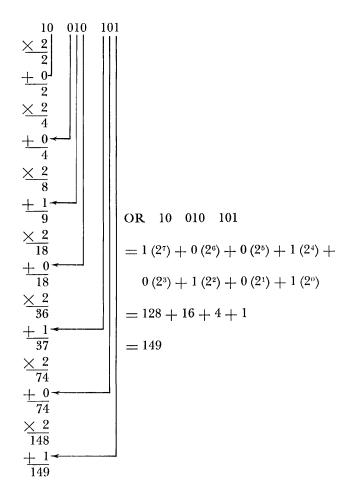

OCTAL TO BINARY BINARY TO OCTAL
$$2$$
 2 5 010 010 101 010 101 2 2 5 $= 225$

DECIMAL TO BINARY

RULE: Divide the decimal number by 2 and develop as per example; convert 149 to its binary equivalent.

BINARY TO DECIMAL

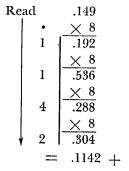

RULE: Multiply by 2 and add as per example; convert 010 010 101 to its decimal equivalent.

Fractions

DECIMAL TO OCTAL

Rule: Multiply by 8 and develop the octal number as per example:

OCTAL TO DECIMAL

Rule: Express as powers of 8, add and divide as per example:

$$.1142 = 1 (8^{-1}) + 1 (8^{-2}) + 4 (8^{-3}) + 2 (8^{-4})$$

$$= 1/8 + 1/64 + 4/512 + 2/4096$$

$$= 610/4096$$

$$= .1489 \text{ plus}$$
or .149

OCTAL TO BINARY AND BINARY TO OCTAL

RULE: The same rule applies for fractions as for whole numbers.

Example:

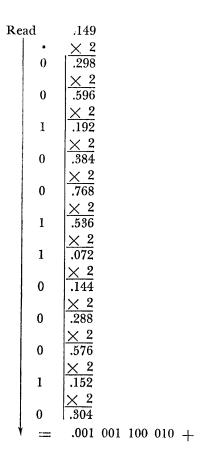

BINARY TO DECIMAL

The same rule applies as for whole numbers; for example:

.001 001 100 010
$$= 1 (2^{-3}) + 1 (2^{-6}) + 1 (2^{-7}) + 1 (2^{-11})$$
$$= 1/8 + 1/64 + 1/128 + 1/2048$$
$$= 305/2048$$
$$= .1489 \text{ plus}$$
or .149

DECIMAL TO BINARY

The same rule applies as for whole numbers. For example:

Improper Fractions

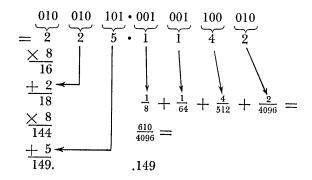

DECIMAL TO BINARY

This requires conversion from decimal to octal and then to binary. For example, convert 149.149 to its binary equivalent.

BINARY TO DECIMAL

This requires conversion from binary to octal and then to decimal.

Convert to decimal:

As with decimal-to-binary, conversion of the integer and fraction parts is performed independently.

Floating-Point Word

DECIMAL TO FLOATING POINT

Convert decimal 149.149 to normal floating-point word.

Decimal to octal:

$$149.149_{10} = 225.1142_{8}$$

Octal to binary:

$$225.1142_s = 010 \ 010 \ 101.001 \ 001 \ 100 \ 010_2$$

Binary to floating point word:

10 010 101.001 001 100 010 \times 20 = .10 010 101 001 001 100 010 \times 28 8 + 128 = 136 (Characteristic)

10 001 000.100 101 010 010 011 000 1 FP

NOTE: Word is normal if the fraction is less than 1, but greater than or equal to one-half.
