#### THE COMPUTER UTILITY AS A

#### MARKETPLACE FOR COMPUTER SERVICES

by

#### Robert Matthias Frankston

#### Abstract

Computers are unique in their ability to be programmed for a wide variety of applications. This is in contrast with hardware dedicated to specific tasks such as the telephone system. Because of its flexibility, a computer system can support, concurrently, many diverse services that do not require dedicated hardware. Conversely, these services act to bring the capabilities of the computer to the consumer who might otherwise find the operational difficulty of running computer programs too formidable.

Since the computer is supporting many services which are sold to consumers it is natural to model the system as a marketplace for these services. Host contemporary computer systems are oriented towards users who run programs. The environment for services puts different requirements on the computer systems than do the needs of programmers, so as to permit all the participants in the market to make effective use of its facilities without requiring dedicated facilities and without interfering with each other. As with any marketplace, it must be convenient to do business within its framework.

The requirements of such a marketplace are not satisfied in contemporary computer systems. However, the marketplace can be evolved from some existing computer systems without fundamental changes. Presently the use of a computer requires considerable expertise use the mark of the user. The evolution to a marketplace is necessary if the capabilities of computer systems are to be made more widely available than they are now.

THESIS SUPERVISOR: F. J. Corbato TITLE: Professor of Electrical Engineering

#### Acknowledgements

I would like to thank Professor Corbato whose insights were invaluable in identifying many of the issues discussed in this thesis. I would also like to thank graduate students and staff at Project NAC who read and commented on earlier drafts of this thesis: Doug Wells, Doug Hunt, Austin Henderson, David Reed and Vic Voydock.

#### CHAPTER ONE

and and a time to the control of the

#### INTRODUCTION

Computer systems have evolved from simple calculators to more sophisticated processors capable of running complex programs with large data bases, to information systems serving the diverse needs of many users. Despite the evolution of hardware and software in the past twenty five years, computers are still regarded by many as esoteric devices for solving well-defined problems. One approaches the computer with a problem, programs the machine (or uses an existing program), feeds in data and the computer prints the results. This mode of operation is being superseded by one in which the roles of the computer and the user are not as well-defined, where the user works with the computer to find the solution to a problem. Even the idea that one must necessarily have a specific problem in mind is being replaced by the view that a computer offers a collection of programs which one may call upon (through a command language) to perform tasks when requested. The tasks may be one of those traditionally associated with the computer -compiling, statistical analysis and report generation -- or they may be used to communicate with one's bank, library or colleagues, to manage household finances, recipes,

Introduction scheduling, or shopping.

R. Frankston

These latter applications are not common for a number of reasons. Some of these are technical -- we often do not have the knowledge to construct programs of the required sophistication. Hany of the difficulties are not technical, but are the result of designing computer systems for running programs. But being able to run a program is not equivalent to being able to make effective use of a computer. The vast majority of computer users, as opposed to programmers, should not need to be concerned with the details of running the programs. By concentrating on the computer as a home for programs one misses the forest for the trees. This thesis will distinguish between the use of programs and the use of services on a computer system. The aim is to examine computer systems as bases for providing services.

and the control of th

The evalution of computers from programming systems to service systems is similar to the earlier evolution from the bare machines to those with the support of sophisticated operating systems with their associated file systems, libraries and other resource management facilities. The service environment provides the vendor with the facilities needed to enable him to present his

The state of the s

services to his users without requiring knowledge of the complexities of the computer system. The telephone system is an example of a complex system dedicated to a limited set of services. When placing a telephone call, a subscriber is using a very complicated communications network, but he need only state his request in terms of the service he is asking for Morsally this is done by simply "dialing" the number of the phoneshes wishes to be connected to. In addition to being shielded from the technical complexities of the phone system; he isaalso shielded from the financial complexities and the politics of dealing with multiple telephone companies. All he sees is a bill stated in terms of the calls that he made : all computer systems has much in common with the telephone system in providing services to ditamubscribers a Hovever sa while the atelephone systemais organized around a limited set to of services, the computer systemisis an environment incomment any adiverse services can be offered. As the telephone scompanies have found solutions to the problems of providing their specific services, the computer systems austaprovide an environment that permits solutions to be applied to a large avariety of services.

provides an enhanced machine. The most important characteristic of this environment is the availability of other services that may interact with each other. In fact, the computer system can be viewed as simply a collection of these services; some being basic, such as the computer hardware and file system, and others being more sophisticated.

en en la companya de la companya de

A description of an environment for offering computer based services is incomplete without lany discussion of the financial or resource management aspects of the environment. In the design of computer systems the problems of buying and selling computer services have largely been dealt with in an ad hoc fashion. In many projects such as the ARPA network, they have simply been deferred. But the viability of a computer system as a marketplace for services depends largely on the ability to transact the business of buying and selling the services. To date, much of the discussion of accounting for computer usage has been concerned with the allocation to costs of or the computer system to its users and with the use of pricing structures to distribute the computer resources according to given policies. This is not, however, the aim softa financial system for a marketplace. In the marketplace, the problem is one of facilitating business transactions, not that of

devising appropriate pricing policies, except to note that prices should be based on measures meaningful to the user of a service. It is important to permit conventional buying and selling to be extended to the marketplace. There is another necessary aspect to these transactions -- the settlement of disputes. In typical computer systems there may be many parties to a dispute, the installation management, the programmers, and the user of the system. In a marketplace, each vendor can make use of many other services. Unless guidelines are established for assigning responsibility when service is not satisfactory, the market becomes unattractive to the user who does not enjoy the details of litigations.

marketplace for services, an implementation will be described. Multics, a system developed cooperatively by MIT and Honeywell, will be used as the basis for such a system. Multics is appropriate because it was designed to serve as a basis for a computer utility. The implementation of the marketplace will serve to demonstrate techniques that can be applied to other computer systems. The principle extensions to Multics will be the creation an environment for services as opposed to programs including a financial system for conducting business in the marketplace.

ានក្រុងស្វែង មាន ទិស្ ក្នុង ។ ប៉ុន្តែសម្រាប់ ស្ថិត

Once the framework of the marketplace has been applied to a single computer system, it can be extended to a distributed computer system such as the ARPA Network. By applying the framework of the marketplace to the ARPA network, some of the practical problems encountered in trying to offer services via the network can be resolved.

#### CHAPTER TWO

## SERVICES IN A COMPUTER ENVIRONMENT

The goals of a computer system as an environment for services and those of structured programming have much in common in that they both represent attempts to control the complexity of computer systems by decompling withe services or modules of the system. Each module is viewed in terms of its interfaces with other programs. In analysing one program the internal operation of the individual programs it calls upon is not important. Back program module is considered to be fully responsible for the service it performs. Though one module may make use of other services, the user of the module is insulated from these secondary services. While this approach has been taken in some large programming projects, the facilities required for properly protecting programs of from unwanted interaction are inadequate in most computer systems.

The computer marketplace and structured programming share the tasic goal of making more effective use of the computer system. The desire for modularity stems from a need to debug a large program by analysis of local

nazi pergantan mengelah kecamatan perganakan berangan pengebahan berangan berangan berangan berangan berangan

到底,这一点一点,这一点,我们就是一个一个人的**那么**有数的。" "我们就是我们的,我们们的一个,我们们们的一个,我们们们们们们们们们们们们们们们们们们们们

Services In a Computer Environment R. Frankston relationships between programs. For the marketplace, modularity means that each vendor takes responsibility for his service thereby relieving the user of concerns about the details of the operation of the service. The ability to assign responsibility is important in localizing bugs in programs. One can determine whether a bug is in one's own programs or not. If not, then the bug is either in another module used in which case, the person responsible for the aboute can be informed, or it is in the interface to the other module. In the marketplace, the clear assignment of responsibility is inecessary for simulating deficiencies in services and for resolution of disputes.

services, an adequate framework must be developed for the financial transactions associated with the buying and selling of services among the participants in the marketplace. Hore then estaply anaking site possible to transact business, the marketplace must make the sale and purchase of its services very convenient. The financial system is, effectively, a system of resource allocation simplified by the use of a common emeasure (money) for exchanging resources. Unlike many systems for accounting for the use of computer resources, the financial system of the marketplace is not meant simply as means of

👫 នេះក្រុមបានការ ២ ជាក្រុម ប្រជាជាជាស្ថិតនៅក្រុម 🔭 នេះ ប្រុម្មិត្ត ប្រជាជាជាធ្វើក្រុម ប្រជាជាធិប្បធានប្រធានប្រ

Services In a Computer Environment R. Frankston allocating costs of the computer hardware, it must permit the assignment of value to resources created by vendors and embodied in the services provided.

· 17、大大大大,一种大大大大大大大大大大大大大大大大大大大大大

The marketplace puts requirements on services other than those strictly dictated by structured programming. If services are to be sold to consumers (as opposed to specialists and sophisticated users) in a competitive market, it is important that the services be attractive to users. In addition to the characteristics of specific services, general factors can contribute to the attractiveness of services. The include:

- Convenience: What is required of the user to take advantage of the service? What must the suser wknow coutside of his particular application area?

in the state of the companion of the problem of the substitution of

- Completeness: Must the user saccess multiple services to accomplish his goal? Can be staccemplish the goal through the use Tof was smalled invaher mof asservices other can accommunicate in a common language?
- Relevance: Can the user "speak" ato the service in terms wearingful to him, or must be learn some special purpose language? Is the service interface oriented atoward the

Services In a Computer Environment R. Frankston user's problem or must the user make the problem match the services available?

roman emission alt collèc collec

- Safety: What risks must the user take in order to use the service? Is the service so powerful that a minor error can be catastrophic? Will the user be able to predict the effect of his request? Does the "principle of least surprise" apply - does the behavior of the service conform to that which the user intuitively expects? What assurances does the use have that the service will be satisfactory? If the service is unsatisfactory, what appeals does the user have?

The aim of creating an environment for computer services is to simplify the offering of services. Some of the techniques have been mentioned above. The primary technique is the decoupling of services by requiring that the vendor of a service take complete responsibility for his service at the interface to the service. This is a prerequisite for the criteria disted above. The service is convenient if the user need not be aware of the details of implementing the service. By taking full responsibility for his services the wendor gives the user a well defined means of finding who to appeal to when any aspect of the service is unsatisfactory. The degree to which a user or wendor can

Services In a Computer Environment R. Frankston be liable in such a situation can be limited by contractual arrangement between the user and the wendor prior to accessing the service.

The financial system of the marketplace also supports these marketplace criteria and is discussed in the next chapter. The problems of developing standards and design criteria for service is a much broader problem than the design of the environment for services and is beyond the scope of this thesis.

The availability of many services, possibly in competition, is necessary to provide a "critical mass" of service wherein one is likely to find a service appropriate for a particular task or one can find a set of services suitable for the task. Services must also be available to be combined for the creation of more powerful services. The competition between services in the marketplace is a primary motivation for making services as attractive as possible. To provide an environment in which all senvices can be made available to the consumer in which all senvices can be made available to the consumer in a uniform manner, it is necessary that the users and services share a common pool of resources. This can be done by sharing a single computer system or by establishing protocols for communicating between services within a distributed

Services In a Computer Environment

Computer system. In this latter case, the marketplace still appears to the user as a single shared computer system.

Since competing services are sharing a common computer system, it is necessary that they can be assured that no service can interfere with any other service either maliciously or accidently. Interference can occur when a database is altered, when a program is stolma, or even when service is unavailable because one user is exhausting the capacity of the system. The elimination of unwanted interfaces must not prevent normal interactions between users and services. Both the vendors and the users should be able to control these interactions so that the vendor can selectively deny access to him mergical so that the user can prevent the vendor having unauthorized access to the user's data or money, and see as no protect the privacy of the subscribers.

The computer system as a programming environment. To a user not doing his own programming the system must provide an interface to its services. The purpose of this interface, which is similar to conventional command processors, is to simplify the accessing of services and to permit business transactions associated with these services to be made

and the state of the second production and the second second

Services In a Computer Environment R. Frankston conveniently. Conceptually the user can be viewed as accessing the services from a typewriter-like terminal, though specialized terminals and interfaces are also possible. It is not, however, reasonable for each service to have its own unique mode of access because the user would be required to learn the idiosyncracies of accessing each service. Thus the computer installation must provide a uniform access interface to services. The user of a service can also be another service so that the interfacing protocol must also be suitable for use by a program without human intervention.

# CHAPTER THREE THE FINANCIAL SYSTEM

As explained in the introduction, a viable financial system is key to the successful operation of the marketplace. The purpose of the financial system is to permit standard business practices to operate within the framework of the marketplace. This differs from the goal of many existing computer resource accounting systems as the emphasis is on the transactions between the subscribers to the computer system as opposed to regovering the costs of the computer system.

rania in alternativa de la compansión de la

The primary requirement for the financial system is that users have confidence in it. Confidence requires not only that the system be secure and trustworthy, but also that the system be convenient and simple enough to use so that the user can be at ease with the system and not worry about being at the mercy of a system that he does not understand. The degree to which the user can trust the financial system depends, in part, on permitting the user to apply his existing experience with the conventional financial system to the new environment as well as on the correctness of the algorithms used and the integrity of the

The Financial System

R. Frankston

computational methods used within the financial system and

within the services offered.

It is inevitable that disputes will arise between the users and vendors of services. Unless dispates are resolved fairly, the participants do not have any recourse within the marketplace in the case of unsatisfactory service. If one must pay for a service even when it has not been provided satisfactorily, the risks involved in using services ma outweigh they spotential benefits. Central to the resolution of disputes is the determination of who the responsible parties ware, for if responsibility cannot be assigned no action can be taken to resolve a dispute? For the vendor, the recourse in a dispute may be to deny farther access to his service. The aser hay apply financial leverage and deny payment antil othe lisages are resolved. The financial system must be able to protect the user's right! to withhold the payments! for services. " In " other words, where financial system is an servant of the participants; paydentserare not made wand services dare not provided vithout this authorization by the interested parties. The winder of the control of temperature talled

In day-to-day business transactions a number of conventions have been established to facilitate common

occurances such as the buying and selling of mechandise and to protect the interests of participants. When the marketplace for service is within a computer system the methods for financial transactions differ from conventional methods because the transactions do not involve physical assets or produce written records. It may be argued that one can continue to apply current practices of using written notes even though the services are within the computer system. This is analogous to receiving a separate bill for each telephone call one makes. The burden of handling the bills for many small transactions would exceed the advantages of such tangible records. In fact, in conventional transactions, the problem of processing many paper transactions is leading to the development of electronic fund transactions systems.

The advantages of a financial system designed for the marketplace is that it can greatly simplify the buying and selling of services. In designing such a system one must provide counterparts to traditional financial safeguards such as giving the subscriber control over his own assets (i.e. no payments without subscriber's permission) and adequate records to give the subscriber the equivalent of such conventional records as receipts, check stubs and itemized bills. Above all, of course, the financial system

PRINET 3

9.4

In the marketplace's financial system, one pays for a service by transferring money from the user's account with the installation to the vendor's account. This transfer is really authorization to the installation manager to consider money formerly being held on behalf of one user to thereafter belong to another user. A record of the transaction is kept by the financial system and functions as a receipt. A bill can be considered the converse of a payment in that it is a request made by a vendor for a transfer of money from the user's account to the vendor's account. For simplicity, we define a standard transaction as consisting of a bill and it associated payment. In practice, the bill may not be paid, or there may not be an explicit bill associated with the payment.

entre et en trafte en experiment de gert begrever Edjourgestjongsprongsprongsprongsprongsprongsprongsprongspro

As pointed out above, the burden of processing the bills from many services can be quite heavy. It is therefore necessary to minimize manual processing of the transactions. Most transactions are fairly standard and can be dealt with in a predictable, or automatic manner. It is only in the exceptional cases that intervention is necessary. Thus one must be able to specify what action is to be taken in the normal cases and what conditions are to be considered exceptional and thereby require human attention. Simple examples of automatic decisions are

The Financial System

R. Frankston
default limits for spending and authorization to pay a bill
when it becomes due.

If the specification of how to process each transaction is itself too complicated, the advantages of automatic processing of transactions is lost. The basic interface to the financial system should permit a simple specification of which transactions require manual processing. The user has the potential of programming his own more sophisticated screening of the transactions but the specifications for payments associated with the standard transactions should be sufficient for most users.

TO THE THE THE STATE WELL THE SERVE WAS BOTH THE BEST FROM THE BOTH

A standard transaction record was described above as consisting of a request for payment (or a bill) and the corresponding payment. In addition to these two items, the transaction record contains a specification of conditions under which payment is to be automatically made. I simple specification includes the (future) date on which payment is to be ande and the maximum amount of payment. This amount is normally the price the weader quotes when the users accesses a service. The users can thus request a service and not have to consider the bill; individually unless it exceeds his limits of q the service is not satisfactory, he has until the payment date he specified to

in a filipe in a car in a day the filipe in the re-

Grouping transactions together into accounts provides the ability to consider classes of transactions. Rather than considering all payments to be made from one large account that the subscriber has with the installation, smaller accounts for specific purposes can be maintained. This has the advantage of permitting limits to be placed on each of the accounts so that an efforwill not threaten the user's total balance. Associated with each account are default values for transactions and total limits for the account. More importantly, the user can delegate authority for managing an account. A user can permit a trusted vendor access to an account to collect periodic payments. He can, however, still limit the total amount that the vendors with access to the account can withdraw. for course, this is against a background of contractual arrangements which may give the user legal rights to still reclaim wis payments if the vendor has not satisfied the conditions of the contract). Another advantage of having multiple accounts is the structuring of the user's records so that he may more easily evaluate his financial position. At the second color

The specification of who can do swhat with a user s account must be formalized so that the user can delegate

"我们们是我们,我是我们的一种"我们"的是自己的是一种的人,但我想要把你们的"我是是什么我们,"我们的"。

The Financial System

R. Frankston

some of the responsibility for managing the account without giving up full control. The ability to limit the amount of responsibility delegated to another subscriber simplifies the user's task of monitoring the use of his accounts. We can define five roles which a subscriber can have with respect to an account. The subscriber's access to an account depends on the roles he is permitted to play.

Owner specify a subscriber's access to the account.

entre la ligación de la companya de

[4] "我此人之"的"人"之,"大学"。""这人"的"美",我就要要说了"我没有看这多的"我<mark>我</mark>不是",也是"这一"。"这是","这么,""一个。"""。

Clerk May examine the status of an account by listing the balance and any transactions associated with the account.

化二溴酚二氢甲磺二丁氨基乙酰酚

Paymaster May authorize payments from the account.

Receiver as May accept payments to the account of the lace

Requestor May make a requests for a payments a from a the account.

in de la completación de la comp

Roles must also be defined with respect to transactions within accounts. A subscriber may be given the ability to change the amount requested (i.e. specify the tangent of the bill), cancel the bill, authorize payment (assuming one has

The Financial System

appropriate access to the account with which the transaction is associated), or to simply examine the status of the transaction.

The system of accounts, transaction records and controlled access permits the user to simplify his own processing of his financial transactions by being able to delegate some responsibility for their management while still maintaining overall control. For example, even when a user delegates authority to make payment on his behalf, he can limit the total amount that can be spent by simply limiting the balance in the account to which he is giving access. Typically he may give access to accountants or others providing financial management services.

#### CHAPTER FOUR

#### AN IMPLEMENTATION OF THE MARKETPLACES

An important criterion in the design of the marketplace is feasibility. To demonstrate the feasibility of the requirements of the computer services and the framework for the marketplace an implementation will be presented. A detailed implementation requires that points be clarified that are vague in the general description, such as the exact method of requesting a service and the exact capabilities of the financial system. The Hultics system developed cooperatively by the Hassachusetts Institute of Technology (Project NAC) and Honeywell Information Systems will serve as the basis for the implementation. See Appendix A for a description of Hultics.

nultics was designed to serve as the basis for a computer utility and thus comes closer to meeting the requirements of the marketplace than other systems generally available. Multics can be extended without great modification to serve as the basis for the marketplace. There are other systems that could also serve as basis for a utility. These include IBH's VB/370 and OS/FS2-2/TSO

in Gorphia man Cal

organistic companies and the companies of the companies o

In specifying an implementation one must first find representations for the elements of the model. Specifically, what are the representations for the installation manager, the subscribers, services and the financial system?

5.45

The installation manager takes on the responsibilities of the Multics system administrator. The subscribers are registered Multics users.

## The reducer of the Services of Seltics American in the con-

en de la material de la companya de

out the way to be the property of the four first rest of the said life the said for the said

A service is essentially any sellable commodity on the computer system. One may simply well access to a data base by subscription and then provide the service by giving the user access to the data. Here interesting are services which actively perform a function and must be represented as a program for the computer. The requirements on services include the following:

There must be no unadvertised side affects. Such side effects are typically the result of sharing resources

ាំក្រស៊ាន នៅជា នេះ នេះ នេះ **ន**ោះ នេះ ប្រជាជាធិបាន នេះ ប្រជាជាធិបាន នេះ ប្រជាជាធិបាន នេះ ប្រជាជាធិបាន នេះ ប្រជាជិប

without clear assignment of responsibility.

- The subscribers must be protected from each other so that one would not normally be affected by the other's mistakes or attempts at penetration.
- The user should consider the service to be "black box" and just view it as something that takes requests and returns results.

The state was the standing of the standing of

TING DEPOTE AND TO A SECTION OF THE PROPERTY O

- The representation should not prevent a service from using other services.

- access to their services applied to a pleaton control
  - Services should be able to operate asynchronously.

ម្រីក្រុង ព្រះ ប្រជាពី ស្រាជ្រាក់ សមុខស្គារ ដែល ស្រា<mark>មទំនាស់ស្រាជ្</mark>ធិក្រុង សម្រើថា ស្រាស់ស្រាក

In Multics, these requirements can be met by running each subscriber's programs in separate processes. Each process is identified with the subscriber's principal identifier (or access name). Thus the identity of the subscriber running a given program can be determined at all times.

The state of the s

Conventions must be established for communicating with services. Since, ideally a service can be viewed as simply taking requests and returning a result, we can associate with each service a queue of requests. For each queue there is (at least) one process that reads the requests and performs the service. The details of the implementation of services as processes associated with queues is described in more detail in Appendix B.

Process creation and communication between processes via queues is not very expensive in Multics, costing approximately a second of processing time for each process created. For many services, however, this expense is too high. Instead of requiring its own process, a service may be a subprocedure in the user's process. There are a number of drawbacks to this approach:

医肾病分析 "我们们的"的现在分词 计一点键 "一一人"的"海道强力,整理" 医盖勒瞳栓 2、秦帝也是他没要称"

- Since the procedure is being run in the user's process, it is difficult to determine who has responsibility for usage of resources.
- Since the service and the user's programs share a common memory (more precisely a common address space), they can easily communicate via shared storage. This use of side effects can obscure the

environment and thus remove the problem of mistrust in one direction. For example, if the vender's service is provided as an inner ring procedure, the user may not circumvent the vendor's protection, but the vendor may still misuse the user's access privileges. Since it is very difficult to provide more than one inner ring procedure in a given process, this mechanism is of only limited utility. In his doctoral themis, Schroeder proposes are mechanism for generalizing rings to permit the use of multiple entually suspicious subsystems in a given process. While Schroeder's domains provide a stable means of promiding some services, they have not been implemented and will therefore not be explored further in the description of the implementation within the context of the existing dubtics system.

# The Financial System on Multics

and the first transfer confirmation where with a confirmation

weeks theilife or old when

The financial system is a special service in that it is offered by the installation analogous and is used by nearly all services and thus austabe efficient. The representation chosen is an inserming (eraprivileged) procedure available in all processes. In Sultics there are eight rings. The innermost are reserved for use by the system and installation and canapage therefore be used in all processes even those that vare already using multiple

An Implementation

R. Prankston

rings. The use of an inner ring has the virtue of being simple and efficient. It also provides a secure financial system though it doesn't protect that subscriber against errors in programs in the financial system, a protection that is superfluous since, in general, one cannot protect against the installation management. Appendix C gives sample sections of the Multics Programmers' Manual Accounting System Supplement and can be referred to for more detailed description of the interfaces referred to below.

the control of the second of the control of the second of

The entry points for programs calling the financial system can be divided into three main groups according to whether they deal primarily with accounts, transactions or services. For accounts, the operations consist of creation, examination, modification of access and termination. For transactions the operations are: creation, authorization, payment processing and requesting, examination and assignment to a service request. Service requests pass the specified parameters to the service. Such a request might also specify a transaction which the service may use for its bill. The transaction specifies an amount authorized for payment so that the payment can be made immediately if the vendors price is within the authorization range.

Accounts are collections of data representing a set of balances and relationships with other accounts. Associated with an account is a set of access privileges. The following items are maintained for each account:

1) balance This is a set of pairs of amounts and units representing the balance on deposit with the installation manager.

and the contract of the contra

2) payables This is a list of transactions representing payments from this account to another account. They may be pending or processed.

The low level entries into the financial system include entries to create accounts, create transactions, specify access, specify quantities for payments and requests, and reading the contents of transactions and accounts. These are described in appendix C. Appendix C also includes the entries used to request services since the financial system acts as the intermediary between services.

the first probability of the court of the street of the court of the c

the Control of the Co

It isn't sufficient to specify the interfaces to the financial system, one must also be able to make effective use of them. The aim of the financial system is to do more than permit transfers of money between users. It is also a means of providing the subscribers to the marketplace with control over their financial denkings. In an environment where there are many transactions being made, effective control means not only that the subscriber be able to decide the fate of each transaction, but also that he is not swamped with details that would render him unable to deal effectively with important transactions. Some examples of simple transactions:

Case one: a user purchases a service and pays in advance. This is similar to a conventional cash purchase except that a record is made of the transaction. The user

An Implementation

asks the financial system to make a payment to the vendor's account. The user then sends the service request to the vendor along with the identifier of the transaction.

case two: a user purchases a service but does not pay immediately. The user may simply pass parameters to the service and the service will in turn make a request for payment to the user's account. In order to do so, the user must give the vendor access to make payment requests and then must consider the request to decide whether to make the payment. A simpler procedure is for the user to create a transaction and then give the vendor access only to the particular transaction. If the user expects the service to be satisfactory, he may specify a maximum payment for the transaction and a date on which the payment is to be automatically made. Thus, unless the service is unsatisfactory or the bill is higher than expected, the user need not be bothered with deciding on payment for the transaction.

Case three: A user wishes to pay a group of vendors automatically but limit the total payment. This is useful in paying utility bills such as gas and electricity. The user can create an account for this purpose and give it a balance equivalent to the maximum allowable payments. He

grange whose star saustrales at aids postquestis bors

An Implementation

R. Frankston

can then give the appropriate vendors access to make payments to themselves and does not need to check transactions individually.

To make most effective use of the markstplace, higher level routines than the interface specified in the appendix would be necessary. These interfaces would be necessary. These interfaces would stake care of many of the details associated with standard transactions. For example, instead of explicitly specifying a date for each transactions, the routines would normally supply a default date such as the end of the marks next billing period. Protocols for more complicated arrangements such as the use of credit from a third party and taken be developed.

The standard user interface to Multics is a command processor that is used to invoke programs. To the user of the marketplace this is unsuitable and a more service oriented interface is necessary. In using the service interface, the user need only specify the services he wishes to use and the parameters for the service. This interface also includes the higher level accounting aids mentioned above. In practice this interface might also be

### DISTRIBUTED SYSTEMS

A network of computer systems linked via communication lines can be considered as a single distributed system. Lesser degrees of distribution are also possible, ranging from a multiprogramming system where the processing is distributed by the software over a number of logical processes, to separate computer systems sharing storage facilities, to separate computer systems with autonomous administrators who cooperate through a small set of well defined protocols. So far we have considered only the first case, a single multiprogramming or (and is possibly multiprocessing) system that is viewed as a homogeneous environment for computer services:

To the user requesting a service, it is not important where the program for the service is being run, as long as the interface to the service is well defined and the parameters can be passed without complications. Before considering the ramifications of extending the marketplace to a distributed system, we must first examine the reasons for having a distributed system.

តា ទៅការប្រើប្រាស់ បានក្រុម បានការបានប្រាស់ ស្រាស់ ស្រែក ប្រែក្រុម ប្រែក្រុម ប្រែក្រុម ប្រែក្រុម ប្រែក្រុម ប្រ

and the first of the control of the

To the consumer, it is inconvenient to use multiple markets. The computer system can be compared with the telephone system. A telephone subscriber doesn't purchase services directly from each phone company. Instead he subscribes to one phone company which provides him with access to the subscribers of the other phone companies. To the subscriber, the telephone system appears to be one large network without the complications of many interconnections and differing taxiffs. In the same manner, the subscribers local market can serve as his entry into the larger system of market places.

And the second s

unlike two subscribers of a stelephone system, at the communication between a speciand as renderate not restricted to a single set of conventions allow additionate parameters explicitly presented by the user a to the container and results explicitly returned as messages, the two parties may communicate via shared resources outside the scope of the restricted protocols for accessing a services of a ceasing a services of a seasony as mencry address to the render. The mender smould then access the data directly in this shared memory. While this may be a simple operation within the confines of a sample computer system, it is note difficulty to extand this mode of communication to a distributed system. For the purposes of

discussion, we will restrict communication between the user and the vendor to an access protocol wherein the user passes messages to the vendor via a queue of requests for the vendor's service and the vendor replies by sending messages to the user via a similar queue used for replies. It should be noted that the name of a service may be passed as a message.

As in a single system marketplace, financial services must be provided. As long as some can approvide a secure environment, interfaces similars to those specified in chapter four can be provided for a common financial system. When there are autonomous administrators, the approach of having a single financial system cannot be autoed vaince the participating sinstallations are autually suspicious. The relationships between the installations as analogous to that between services at a single installation. Each installation maintains an account representing its status with respect to each other installation. Periodically the installations must make actual cash payments to resolve imbalances.

when a user authorizes payment to the vendor, he is telling his installation to authorize apayment by the vendor's installation to the vendors if the vendor's

installation makes this payment it is, in effect, trusting the user's installation to make the payment when the accounts are resolved. This requires that each pair of installations establish a credit/relationship. coThe number of such relationships grows with the square continuaber of a sinstallations a crie assaints in side for the continue of the form of the continue of th relationships is cumbersome. To reduce the number of relationships, an intermediary can be introduced as a clearinghouse for the transactions between installations. This clearinghouse is fulfilling similar functions to the installation manager at a centralized marketplace, with its -associated benefits. Just as the Spreamdenof as market place financials systemedoes inot aprechadeaspecials aprangements between ventors ouse of the clearinghouse is Lyolantary, what distriction and the street of Finstallations manageable. As as it said minrated tendered that it

computer system. It is composed of autonomous computer systems linked together through and accessage switched communication system. The importance of the network is in its attempt to define protocols to permit the cooperation among users of these diverses computer systems. These protocols have so far been mainly concerned with the use of resources at one computer installation; by users at another

installation. The network has been used by some subscribers to purchase services from remote installations.

The same to be broken to be a second

In order for a user to access a resource on a computer system he must first make arrangements to pay for the use of these resources beforehand. This requires that he either have an account with that computer installation or that the installation provide a common account for network users without charging each one individually. For many users the difficulties of making special arrangements outweigh the advantages to be gained from such sharing. It is also difficult for a service to make transparent use of the network, i.e. if a user calls upon a program at his local installation, the program cannot make use of a service at a remote installation without the user having made prior arrangements — the user cannot treat the service as a "black box" but must be aware of the services it invokes in turn.

A financial protocol can be established to facilitate the use of and payment for resources at remote installations. Each installation on the network is, in effect, a marketplace offering services to its subscribers. The financial protocol permits financial systems at two installations to request and authorize payments at the Distributed Systems

### CONCLUSIONS AND COMMENTS

Commission of the second commission of the second

The aim of this thesis has been to explore some of the difficulties that have inhibited the growth of computer-based services and the converse problem of how to make the capabilities of computers available to users. The solution to the problem of making more effective use of computers involves a combination of computer technology and human engineering. The thesis thus addresses both requirements for a consumer oriented computer system and for the technology needed for its implementation.

supporting services sinvolves more than just writing computer programs to perform specific applications. The services must be provided within a context that permits the user of the services to be unencumbered by the complexities of computer systems without giving apathed conveniences that he is accustomed to with the reconventional services. It is important that he have confidences in the services and in the marketplace. This confidences depends on a suser's ability to protect the effects of this actions and so whis ability to protect what he considers to be his rights of at least to limit his risks.

For the wendor, the marketplace must provide an incentive for creating services. The marketplace, by permitting the wendors to sell services for a profit, supplies some of this incentive. Competition within the marketplace helps ensure that the services sold will be attractive to users.

ျခင်းနှင့် ကြာလေသည်။ မရာရန်သည်သည် သည် သည် သည်။ မြောင်းသည် မြောင်းသည် မြောင်းသည်။ မြောင်းသည် မြောင်းသည်။ မြောင်

Disputes will inevitably arise and must be easy to resolve in common cases. Fundamental to this resolution is the assignment of responsibility code wendor must take complete responsibility for this service both to provide a simple (and thereby attractive) intenface and to give the user someone who can be held accountable for funsatisfactory service, even if the ultimate cause of the problem may be a secondary wendor who supplies a share esservice ato the primary wendor.

Basic to a free market ised atrastworthy dinancial system. Unless the subscriber can chave confidence in the financial system, the subscriber can chave confidence in the market place. Assertated above, a confidence requires predictability and safety as Bysobuilding apong the suser's experience with a conventional obsainess stransactions, in the financial system sofether market places in tended of total low him to have enough of an intuitive above sofether

tinner i til flogt til kommitte kritik kritik **ligter bablikkligg** had ørden in likturen.

financial system so as to be able to predict the effects of his actions. To protect his rights, a user must be able to selectively deny payments to vendors as a way of protesting unsatisfactory service. But it isn't enough for it to be possible for the user to exercise control, it must also be easy to do sc. To prevent the user from being swamped by a large number of transactions, the financial system provides capabilities that permit him to automate his financial management and restrict his attention only to the exceptional situations.

The marketplace, as described in this thesis, is feasible to implement within present day technology. To demonstrate this feasibility, an implementation has been described based on Honeywell's fultics system. While changes are required to the system, these are relatively minor and do not affect the basic structure of fultics. The changes need not even interfere with existing methods of using the system. The implementation has been extended to a distributed system since a large marketplace would exceed the capabilities of a single computer installation.

ក្រុម ប្រធានសម្រាជា ស្រុក មិន**នាស្ទាស់ទី ខាងស្លាំង។ជា**ស ក្រុម សម្រាជិ

The thesis has, by necessity, been limited to those topics immediately relevent to the implementation of the marketplace. Hany of the topics that were mentioned were

Conclusions and Comments

R. Frankston

explored only to the degree necessary to establish that the difficulties they presented were surmountable, but the solutions were examined in only a common fashion. The prime omission has been a full discussion of the interface to the consumer except where used in examples and where used to define basic requirements for the low level interfaces. The omission has been intentional because our understanding of the relevant issues has been limited by the currently available environment for such services. Given the environment of the marketplace, remeatch in the design of the services themselves can be carried out.

ការស្រាស់ ស្រាស់ ស្រីសាស់ ស្រីសាស់ សារាសេស ស្រែសាស្សាស្រីក្រោស់ស្រាស់ អូម៉េសិ

other topics omitted include the legal aspects of the marketplace, the detailed implementation of the financial system, and the limitations of a system such as multics as a basis for a marketplace. The degal quentions faced in the market place involve the problems of rules governing the market as a whole - should it be regulated, what constraints are there on the installation sanagement; and the problems of relationships between meers - what contractual arrangements are appropriate, what implicit or common law obligations do the parties have? The financial system must be very robust (i.e., vinance to contact phe), even though the environment in which it runs may not be very reliable. Bultics has been designed as a basis for a

Culamber tank bernya (1886) any kaominina

computer utility but suffers from some of the same errors of omission as this thesis. For example, is the system sufficiently reliable; is the security system appropriate for the "real world" when the walue of breeching it is high?

Beyond the detailed issues of the marketplace are the questions of the implication of the marketplace as a microcosm of an economy and the relationship between the marketplace and society as a whole what are the effects of mapping caristing constitutions esuch clases banks, a credit bureaus, insurance, communications systems (including the post office) / etc, into a computer systems marketplace. Some of the problems will be intrinsicate any marketplace, but others will arise from the nature of the computer system. For example, the consumer as would not be constrained by geographic considerations sing whhere dection weft services He will also be ablesto wise the computer as an aintermediary between himself and othe services he is maing. AsHe may sefor example, have a program which gives him a personal record of each transaction with a regimenous service scalar and important consequence of the low capital necessary to create a new service is the opening of a the market place to chordes of small entrepreneurs. What sare the sadmantages sof sauch as flea market? What care the disadvantages? What regulations are

医二氏结合 化磁压 医电路 海流 医二甲基酚

Conclusions and Comments appropriate?

The social effects of such a marketplace are hard to foresee at this time. We can only speculate. It is possible that such a marketplace can become a significant social factor since it provides a very good environment for many services especially those that frinvolve scommunication between people where some intelligent processing is necessary. The current system of banks and oredit agencies is an example. The marketplace is lalso suitable for services that require simple, but personaldized processing such as catalog shopping for lithrary services and oth of these also rely on the ability to accommicate with a shared pool of information. The effects of lessening reographic and national restrictions con information sharing must not be overlooked. This is an extension of the information flow made spossible oby telephonese and aimplanes. Binally so what are the inplications of globally days aleble technical expentise, as supplied by computer based services?

The marketplace model of the computer asystem is an idea whose time has come. The costs of scomputer hardware are decreasing so that the necessary computational power is becoming available. In fact, the major rost of scomputer hardware today is the overhead of newstesearch and support

ି ଅନ୍ୟାନ୍ତ ଓ ଏହି ଓ ଓ ଏହି । ଏହି । ଏହି । ଏହି । ଅନ୍ତର୍ଶ୍ୱର ଅନ୍ତର୍ଶ୍ୱର ଅନ୍ତର୍ଶ୍ୱର ଅନ୍ତର୍ଶ୍ୱର ଅନ୍ତର୍ଶ୍ୱର କ୍ଷାଣ୍ଡ ।

Conclusions and Comments

R. Frankston personel. As more hardware is sold, this cost can be spread thinner. Software represents a large portion of the expense of a computer system and the expertise for developing computer services is a scarce resource. The marketplace framework eases the burden of development of computer services since it permits the development to be decentralized among individual entrepreneurs, although although the availability of the marketplace will not cause the problems of implementing service to disappear.

#### APPENDIX A

### Description of Multics

Multics, as a system, performs two main functions: it distributes computer resources among the users of the system and it provides an environment for running programs. The resources consist of the hardware and the software. The hardware is made up of processors, memory, mass storage, communications facilities and other peripherals. Minimal distinction is made between the system software and the user software. The system consists of a privileged supervisor which supports the virtual memory environment and manages resources, and a non-privileged portion.

process is equivalent to a job or a stack in common operating systems. It is defined by an execution point (i.e. a location counter) and a mapping of names in the storage system to addresses in the processes memory. The address itself consists of two parts, a segment number and an offset within the segment a segment is, as its name implies, a piece of memory and generally corresponds to a single program or a data file; Multics makes no distinction between the two. Two processes persenting the same segment

A description of Multics

R. Frankston

may know the segment by different numbers, but will reference the same data; if one process changes a word in the segment, the other processes will be able to read the new value immediately.

The Control of the Co

The storage system corresponds to more traditional file systems. The important difference is that once a segment in the storage system has been initiated ("opened") by a process (either explicitly or implicitly it becomes part of the directly addressable memory of the process. The storage system consists of segments and catalogs of segments called directories. A directory may also contain other directories and thus the storage system forms a tree structure with the leaves being directories and segments.

Segments of memory form the basis for the controlled sharing of information. Each process has essociated with it a principal identifier (or access id); that is formed from the user's name. Each segment (has a disto of these identifiers and what access each has to the segment. Thus one user may be designated as having access each has segment while another may also weaks data into it.

states found in many operating correction and problem

is not aborderalised of Charlesop Spb growed in amorig a consideral

system of rings. There are currently eight rings in Multics. The most privileged or innermost ring is ring zero. In designating access to a segment one may specify the rings in which the access is available. If one, for example, designates a procedure to be readable in rings less then four, but only writable in rimes less than three, the user in ring three may then use the segment normally as long as he is not modifying it. To modify it, he must call a program in ring two or below. This Ting two program may then check the user's request for validity and, in effect, extend the hardware access control mechanism by providing arbitrary mechanisms via softwarel For example, access to a data base may be via an inner ring procedure which will return aggregate values, but not permit an individual item to be examined. data item. The limitation of inner ring procedures is that, if they are mutually suspicious, not more than one can be used at a time in a single process.

Multics administration consists of three levels: the system administration, the project administration The system administration is in charge of maintaining the system integrity, creating projects and registering users. The purpose of registering a user is to guarantee that his user name will be unique throughout the system so that it may be used as an identifier.

Registration, per se, does not give the user access to the computer system. This is done by the project administrator. The project administrator can designate a list of users who may login using his project's name. The project administrator is responsible for the resource usage by those on this project. He may also specify individual spending limits for his users. Users any excercise control over access to their resources by specifying which users control list associated with a segment specifies which users (or projects) may read, writes or extend the segment.

#### APPENDIX B

Implementation of Service Queues on Hultics.

Chapter four presented a model of a service as a queue of requests and a server for the requests. Such a facility can be implemented with minimal change to Multics. The following three facilities provide a sufficient basis:

- 1. Hessage segments. Hessage segments are queues managed by inner ring system procedures. The are implemented using segments in the storage system, but users may only access them through these system procedures. Users may have access to add entries to a queue; list, read and delete their own entries; and to list, read and delete their own entries.

  Associated with each sentry secure identification of the user creating the entry.
- 2. Multiple processes. Multics users may currently have processes created on their behalf. To use this facility, the user sends a description of the process to be created to an absentee process coordinator via a message segment. The absentee coordinator schedules the process to be created as

if it were a job on a batch processing system. Process creations are deferred until the number of processes created in this manner is below the maximum allowable. To make effective use of services, it is necessary to ease the restriction on the number of processes that may be created on behal of users. This restriction is present mainly to simplify resource scheduling.

3. Interprocess communication Interprocess communication permits coordination of processes by enabling processes to send signals to each other. Processes may go blocked in each process may go blocked in each signal. For example, a process might go blocked maiting to read a nessage from a queue. Then another process puts a nessage in the queue, it can wakeup the waiting process who can then read and process the message.

the control of the co

By relaxing the restriction on the number of process that a user can create, and providing better tools for managing these processes (such as the ability to kill a runaway process), processes can be created as necessary to perform services. A service can be requested by putting a

Service Implementation

The state of the Residence of the Prankston

message in a queue. Associated with the queue is at least one server process. When the service a request is put in the queue, a wakeup signal is sent to the server associated with the queue. If the server is not processing any other requests at the time, it would then read and begins to process the users request. If its is busy, the request will be processed when the server is finished with the request it is busy processing. By combining message segments and interprocess wakeups into one facility, the entering of the request and the notification to the server is a single operation.

After system initialization, there are no active servers associated with a gueue. Thus, if there are any pending requests, or when the first request is entered, a process must be created to act as a server. The description of the process is associated with the gueue and together they form the representation for a service in the Multics storage system. More than one process can be associated with the gueue so that the service may handle more than one request simultaneously.

An example of a service in the current Multics system is the output daemon which takes requests for bulk printing and punching. There is one server process for each output

V

Service Implementation

R. Frankston

device. In the current implementation, these processes are created when the system is initialized, or must be created explicitly by a operator. It is not, however, necessary to create these processes before they are requested. If there are not processes available to handle a request (and the maximum number of processes specified for the queue have not already been created), a new process can be created.

#### APPENDIX C

Functional listing of entries into the financial system.

The financial system is \_available to all other services of the marketplace. Since it is so central to the operation of the marketplace and is required for most transactions between services; appellal? consideration must be given to its implementation. For this reason, the system is implemented as a set of inner ring procedures within Multics. To the programmer, this means that the financial system is accessed by using the standard furtice subroutine call mechanism. Since the system is in the control of the system is accessed by using the standard furtice subroutine call mechanism. Since the system is in the control of the financial system databases.

The interfaces (or entry points) of the financial system can be roughly divided into three categories: those that deal primarily with managing and accessing services, those which permit management of abcounts, and those which are used to manage individual transcriptions.

def\_payment\_status\_

The entries for requesting services are included in this appendix because the financial asystem acts as the interface between the services.

Banks' Power Questioned (EFTS vs. Citizens' Rights)
Computerworld, 11/7/73, Vol VII, Number 45, Page 1

R. Frankston

Bibliography

Presents some of the problems with the Electronic Fund Transfer Systems as they are being implemented. The current systems seem to be reducing the individual's ability to protect his interest. Further, discussion of this topic can be found in the following issue of the newspaper. Computerworld has been following these issues in many articles and is generally a good source for information about computers threats to individual rights.
