Programming Manual

PBC 1004 Revision 1

pb Packard Bell Computer

NOTICE

PREFACE

This manual is a guide to programming the PB250. Although a great deal of this material is similar to that which is included in the PB250 Reference Manual, it is presented here in more detail. The information provided in this manual will be useful in actual programming operations. Supplements and modifications to this manual will be published as a series of Programming Notes to be distributed to personnel possessing Programming Manuals.

PB 250 General Purpose Digital Computer.

I. GENERAL PB250 CHARACTERISTICS

1.1   INTRODUCTION

The Packard Bell PB250 is a high-speed, completely solid-state general purpose digital computer in which both the data and the commands required for computation are stored in a homogenous memory. The storage medium is a group of nickel steel magnetostrictive lines along which acoustical pulses are propagated. At one end of each of these lines is a writing device for translating electrical energy into acoustical energy. At the other end of each line is a reading device for translating acoustical energy back into electrical signals. By rewriting the stored information as it is read, information continously circulates without alteration, except for alterations which result from the execution of the computer program. Use of the optional battery power supply will preserve memory information even during power interruptions.

1.2   MEMORY ORGANIZATION

The memory of the basic PB250 contains ten lines, numbered octally (base eight) from 00 through 11, which may hold both data and instructions. Each long line, 01 through 11, contains 256 (decimal), or 400 (octal), locations, also called sectors, that are numbered 000 through 377. Note: All sector and line numbers are given in octal notation throughout this manual. Since the information in any location can be either data or a command, the generic term "word" is used to cover both. The location of any word is specified by a sector and line number (SSSLL), and these together are called an address. Line 00 is a 16-word Fast Access Line. Since line 00 is 1/16 the length of a long word line, any unit of information contained in it is available 16 times during each complete circulation of the 256-word lines. Any word in the Fast Access Line is identified by one of 16 channel addresses (see Recirculation Chart, Appendix D). Line 00

channels are designated F00 through F17. For example, channel F00 of the line 00 can be identified by the following addresses: 00000, 02000, 04000, 06000, ... 36000.

Fifty-three additional lines, each of which may have from one to 256 words, can be added. These lines are numbered 12 through 36, and 40 through 77. Line number 37 is used for the Index Register. If all of the additional lines are used, and if all hold 256 words, the memory capacity of the PB 250 is extended to 15,888 words. The PB 250 cabinet can hold a total of 16 lines.

Commands can be executed only from lines 00 through 17; these lines are therefore designated "Command Lines."

1.2.1   Data Word Configuration

Every number stored in the PB 250 is represented by a series of pulses which correspond to a series of zeros and ones that are the digits of the binary number system. The term "binary digit" is usually contracted to the word "bit." (A discussion of binary numbers may be found in Appendix A.)

A number stored in a location in the PB 250 consists of twenty-one bits that represent magnitude and a twenty-second bit to indicate sign. A negative number has a one in position zero, whereas a positive number has a zero in position zero. Negative numbers are expressed in their 2's complement form. (A discussion of complementary arithmetic may be found in Appendix A.) Figure 1-1 shows a PB 250 data word configuration.

+ -																					
Figure 1-1. Data Word Configuration

These 22 positions are sufficient to represent a 6-digit decimal number.

1-2

Larger numbers may easily be represented by using the double precision features of the computer.

1.2.2   Arithmetic Registers

Three arithmetic registers, A, B, and C, are provided for arithmetic operations and information manipulation. Each register has exactly the same format as a memory location, including the sign, and all are available to the programmer. Double precision commands treat A and B as a double-length register. The contents of a register may be tested for non-positive values or compared against the contents of any memory location. In addition, information may be interchanged between A, B, and C. A record may be kept in one register of operations performed on the others.

1.2.3   Index And Buffer Registers

Both the Index and Buffer registers are part of special one-word registers. When loading the A, B, or C registers from either the Index or Buffer registers, suitable masking should be employed to avoid reading extraneous information.

1.2.3.1   Index Register

The Index register, which is part of the machine Instruction register (see Figure 1-2), stores a line number for use with commands which have an Index Tag of one. When used, the contents of the Index register replace the line number of the address in the command. This replacement is made during the reading of the command, but does not change the command as its stands in memory. For example, if the contents of the Index register are 01, then in the execution of the following program step:

OP Code	Address	Index Tag
ADD	03204	1

The contents of 03201, instead of the contents of 03204, will be added to the contents of the A register.

Line number 37 is reserved to designate the Index register. Addresses 00037 through 37737 all apply to this register, and bit position 16 through 21 are the useful positions for the line address. Thus, a STA into line 37, any sector, places bits 16 through 21 of A into the Index register, bits 16 through 21.

0 7	8 15	16 21
Operand Sector Counter	Sector Counter For Next Command	Index Register

Figure 1-2.   Index Register

The term "effective address," as used in this manual, means the actual location referred to by the computer when executing a command. In the event that the Index register is used, the effective address consists of the sector address specified by the command, plus the line address stored in the Index register, which replaces the line address of the command.

1.2.3.2   Input Buffer

The Input Buffer is part of the machine Sector Counter (see Figure 1-3). It receives the input from the Flexowriter and can accept up to an eight-bit character. This entry is logically accumulative for each bit of the character, requiring that the buffer be cleared before each input. The Input Buffer is enabled to accept information by either a READ TYPEWRITER KEYBOARD or a READ PAPER TAPE command. The single character sent by the reader, or provided by the depressed typewriter key, is loaded into

the buffer and, upon completion of buffer loading, the computer is signaled by the Flexowriter. This action requires a period of time during which it is possible to execute a large number of commands.

1.3   COMMAND WORD CONFIGURATION

As previously described, information in any memory location may be either data or a command. When the information is a command, it has a definite configuration, or format, as illustrated in Figure 1-4.
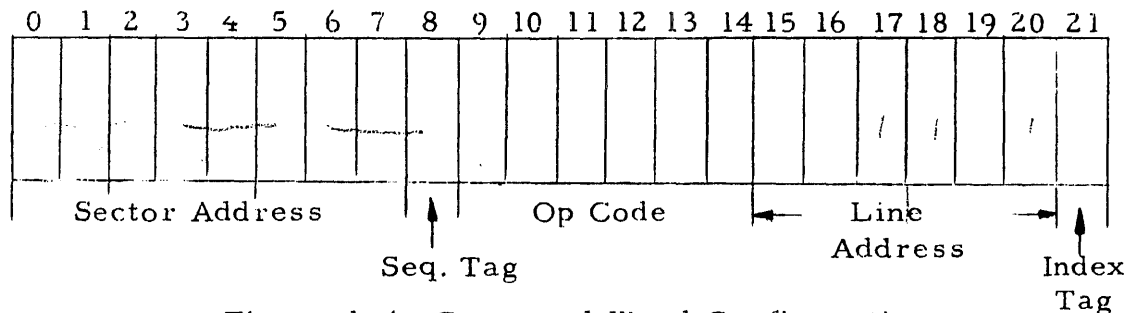

Figure 1-4. Command Word Configuration

Each subdivision, or field, of the command word is uniquely identified. The subdivisions are the sector address, sequence tag, op code, line address, and index tag fields. There will be frequent references in subsequent descriptions, to the address field of a command. Although the address is made up of a sector number and a line number, these numbers are not contiguous in the command format. The address field, however, is considered as a single entity. The address 03204 refers to sector 032 line 04. The contents of the address field in a command do not always designate a memory location.

For example, the shifting commands use the address field to indicate the number of positions to shift.

The sequence tag field may contain either a one or a zero, and its use is detailed in paragraph 1.4 "Command Sequencing and Timing."

The op code field contains a numeric code which specifies one of the PB250 commands.

The index tag field may contain either a one or a zero. When a one is placed in this field, the contents of the Index register are used (see paragraph 1.2.3.1); a zero in the field indicates no use of that register.

Bit position 20 contains a one only when referring to a line address of 40 or greater. For example, an LDA command referring to sector 30, line 42, has an address of 03042 and appears as shown in Figure 1-5.

0							21

Figure 1-5. Typical Command Word

1.4   COMMAND SEQUENCING AND TIMING

The PB250 reads and executes commands from the circulating command lines. The words of the long lines are read serially in sector address sequence (000, 001, 002, --- 376, 377, 000, 001, ---). The time for each word to pass through a reading device is 12 microseconds; therefore, the time for all 256 words of a long line is 3072 microseconds. The performance of each command involves four phases:

1-6

Phase I	Wait to read next command.
Phase II	Read next command.
Phase III	Wait to execute command.
Phase IV	Execute command.

For example, a command 00001 to store A in 03004 will be read (Phase II) in sector 000, held for execution (Phase III) in sectors 001 through 027, executed (Phase IV) in sector 030, and held while waiting to read the next command (Phase I) in sectors 031 through 000. Phase II will follow in sector 001, causing the next command to be read from location 00101.

There are four classes of commands in which the nature of Phase IV differs. A tabulation showing the class into which each command falls is provided in Table 1-1. This tabulation is referred to extensively in Section II of this manual.

1.4.1 Class 1

In this class of commands, execution always follows the reading of the command by skipping Phase III. The sector address of the command is used to designate the first sector number in which Phase IV is discontinued. This class of commands consists of all those which require an extended interval of execution, such as block transfer, shifting, and multiplication. The execution time for this class of command varies with the required duration. For example, block transfer requires 12 microseconds per word, shifting requires 12 microseconds per bit, and multiplication requires 12 microseconds per multiplier bit.

1.4.2 Class 2

In this class of commands, execution is always completed in the sector specified by the sector address of the command. This class consists of all one-sector operations such as load, store, add, and clear. All com-

mands of this class require 12 microseconds to execute. *See RTK (P. 2-51)*
for explanation of modified class 2.

1.4.3 Class 3

Class 3 is an extension of Class 2 to handle double precision operations. As in Class 2, execution always starts in the sector specified by the sector address of the command, but the execution phase is always extended into the following sector. All commands of this class require 24 microseconds to execute.

1.4.4 Class 4

Class 4 consists of commands for conditional and unconditional transfer of control. The condition for a conditional transfer is tested in Phase II and, if the condition is met, the next command is read from the line and sector number specified by the command. If the condition is not met, the command directly following the transfer of control command is read. A conditional transfer where the condition is not met, thus requires no execution time. The unconditional transfer selects the next command with no restrictions. The execution time, when control is transferred, is 12 microseconds per sector for the interval between the transfer of control command and the next command.

1.4.5 Sequence Tag

With commands stored in sequential sectors, the indicated command sequence will proceed at the rate of one instruction per (3072 + 12) microseconds. To provide for a higher computation rate, a Sequence Tag of one may be used in bit position 8 of commands in Classes 1, 2, and 3. The use of this option will cause the next command to be read in the sector directly following the end of the execution phase. For example, a command in 00001 to store A in 03004 will be followed by the command 03101 if the Sequence Tag is a one.

-8

1.5   PARITY CHECK

Each memory word carries an additional position for an even parity check. This position is not under program control and need not concern the programmer in the design and coding of his problem. The parity check is generated during the execution of the STORE and MOVE commands and is tested when loading the arithmetic registers, during adding and subtracting operations, and when reading commands.

Computation will stop on a parity error, and may be restarted by clearing the parity flip-flop with the BREAKPOINT switch and the ENABLE switch of the Flexowriter.

The actual PB250 word consists of 24 bits, of which 22 are accessible to the programmer. A parity bit precedes bit position 0 (see Figure 1-1), and a guard bit follows bit position 21.

TRANSFER ON EXTERNAL SIGNAL	TES	(77)

* Asterisk indicates that the OP code has at least two meanings, depending on the address used with the command. See Section II for a detailed description of the commands.

II. PB 250 COMMANDS

2.1 GENERAL

2.1.1 <u>Command Structure</u>

For each PB 250 command, a 3-letter mnemonic code has been devised. These mnemonics are derived from an abbreviation of the command names and are a convenient device for remembering the function of the command.

When writing a command word, the language of the Octal Utility Program (Appendix C) will be used. This language is the standard language for the communication of programs. Thus, referring to the illustration of a typical command word (Figure 1-2), the fields are written as follows:

a) Sector Address: Three octal digits specifying the particular sector to be used ($000 \leqslant SSS \leqslant 377$).

b) Sequence Tag: If sequence tag is present, a capital S will be written; if no sequence tag is used, a blank space will separate the sector address and OP Code.

c) Operation Code (OP Code): Two digits which indicate what command will be executed.

d) Line Address: Two octal digits specifying the particular line to be used ($0 \leqslant LL \leqslant 77$).

e) Index Register: If the contents of the Index register are to replace the line address, there will be a capital I at the end of the command; if the Index register is not being used, there will be a semi-colon (;) at the end of the command.

The following two commands illustrate this procedure:

$$\underbrace{017}_{a} \quad \underbrace{S}_{b} \quad \underbrace{37}_{c} \quad \underbrace{03}_{d} \quad \underbrace{;}_{e}$$

$$\underbrace{002}_{a} \quad \underbrace{}_{b} \quad \underbrace{05}_{c} \quad \underbrace{02}_{d} \quad \underbrace{I}_{e}$$

Note: The letters a, b, c, d, and e refer, respectively, to the sector address, sequence tag, op code, line address, and Index register.

2.1.2   Command Descriptions

In this manual, the notations A, B, and C will be used to refer, respectively to the A register, B register, and C register, while M will be used to refer to a particular memory location. Parentheses around the letter indicate the contents of the register or memory location; e.g., (A) refers to the contents of the A register.

The "contents of" always refers to all 22 bits of the appropriate register or memory word, unless indicated otherwise by numerical subscripts. These numerical subscripts tell to which particular bits reference is being made. For example: $(A)_{0-10}$ refers to bit positions 0 through 10, inclusive, of A; $(B)_5$ refers to bit position 5 of the B register; $(01502)_{3-6}$ sector 15, line 2, bits 3 through 6.

"Effective address" will be used to mean the actual address employed by the computer in execution of a command; if the Index register is used, then the effective address will be the contents of the Index register and the sector address specified by the command word.

It should again be noted that throughout this manual all op codes, line numbers, and sector numbers will be in octal notation.

Command descriptions in this section will consist of four parts, or less, as required. These parts will be:

a) Description: Details of what the command does - - its effect on registers, memory locations, etc.

b) Example: Specific numerical example showing the appearance of the registers and relevant memory locations before and after execution of the command. (In the case of such basic commands as CLEAR A, STORE A, etc., no example is given.)

c) Timing: The timing classification of the command plus, as required, optimization information such as addressing for optimum timing.

d) Usage: Exceptions to the use of the command or examples of how the command may be used. (Especially useful in such commands as GRAY TO BINARY and EXTEND BIT PATTERN, whose use might not be readily apparent to the programmer.)

2. 1. 3   Special Considerations

Codes 27, 54, 74, and 76 are unassigned and should not be used by the programmer. In the event that these op codes are used, the computer will not halt but will try to execute a command unintended by the programmer.

Certain computer commands operate in a modified manner as determined by the address of the command. These modifications are either described under the commands to which they apply or, if more appropriate, listed as separate commands.

It should be noted that sequence tagging (as described in Section I) never permits the command execution sequence to transfer to a different line, except in the case of a TRU. That is, if the computer executes a sequence-tagged command from line γ , the next command will always be executed from line γ , regardless of sequence tagging - - except in the case of a TRU command with a line address $\neq \gamma$.

Note: The term "execution time," as used in this section, includes the 12 micro-seconds needed to read the command in addition to the time necessary to perform the required operation.

00	HLT	halt		31	DVR	divide remainder
00	MAC	merge A into C		32	MUP	multiply
01	IAC	interchange A+C		33	SBR	shift B right
02	IBC	" B+C		33	LRS	logical right shift
03	ROT	rotate A, B, and C		34	TCN	transfer if C negative
04	LDC	load C		35	TAN	" " A "
05	LDA	load A		36	TBN	" " B "
06	LDB	load B		S37	TRU	transfer unconditionally
07	LDP	load double precision		40	EBP	extend bit pattern
10	STC	store C		41	GTB	gray to binary
11	STA	store A		42	AMC	and M and C
12	STB	store B		43	CLB	clear B
13	STD	store double precision		44	CLC	clear C
14	ADD	add		45	CLA	clear A
15	SUB	subtract		46	AOC	and or combined
16	DPA	double precision add		47	EXF	extract field
17	DPS	" " subtract		50	DIU	disconnect input unit
20	NAD	normalize and decrement		51	RTK	read typewriter keyboard
20	NOR	normalize		52	RPT	read paper tape
21	LSD	left shift + decrement		53	RFU	read fast unit
21	SLT	shift left		55	LAI	load A from input buffer
22	RSI	right shift and increment		56	CAM	compare A + M
22	SRT	shift right		57	CIB	clear input buffer
23	SAI	scale right + increment		6X	WOC	write output character
24	NOP	no operation		70	PTU	pulse to specified unit
25	IAM	interchange A + M		71	MCL	move command line block
26	MLX	move line X to line 7		72	BSO	block serial output
30	SQR	square root		73	BSI	block serial input
31	DIV	divide		75	TOF	transfer on overflow
				77	TES	transfer on external signal

This command stops computation under the conditions noted below and turns on the parity error indicator light on the console. The OPERAND lights on the console will indicate the line address associated with this command. To continue execution of the program, the ENABLE switch and the BREAKPOINT switch on the Flexowriter must be depressed. This will turn off the parity error indicator and, upon release of the ENABLE switch, the program will continue. This command will not stop computation if the sector address equals $a + 1$, when the HLT command itself is located in a. (See MAC description.)

Timing: HLT is a class $\mathbf{1}$ command. If parity is cleared, and the HLT command is sequence tagged, the next command is executed from β, where β is the sector address. If the HLT command is not sequence tagged, the next command is executed from $a + 1$, where HLT is located in a.

Usage: Error halts in a program are easily identified if difference line numbers are used, thus providing a ready means of determining the location within the program at which the computer has halted, the line number being read from the console lights. The Octal Utility Program uses HLT $37)_8$ to indicate a checksum error.

This command is a special case of HALT (00). If a HALT command is given which has as its sector address $a+1$, where a is the sector of the HLT, the program will not halt. Instead, there will be a logical A OR C executed, with the result appearing in C. The contents óf A are merged into the contents of C; a one is placed in those bit positions of C in which there are ones in the corresponding positions of A or C or in both. All 22 positions of A and C take part in this operation. The (A) and (B) are not affected by this command.

Example:

	(A)	(C)
Before execution of MAC	01100101	11010101
After execution of MAC	01100101	11110101

Timing: MAC operates as a class 2 command, being executed in sector $a+1$. If the sequence tag is 1, the next command executed will be in $a+2$; whereas, if the MAC is not sequenced, the next command follows from sector $a+1$. Note that this is different from a sequenced halt command, when the next command comes from the sector specified.

Usage: When the C register is cleared before execution of MAC, the command effectively functions as a "copy A into C", that is, the contents of A are duplicated in C. When using this command, it should be remembered that the sectors are addressed circularly, with sector 000 following sector 377.

2-6

The contents of the A register are loaded into the C register, and the contents of the C register are loaded into the A register. These operations occur simultaneously; thus, no information is lost.

Example:

	(A)	(C)
Before execution of IAC	+ 0 12 3456	+ 6543 2 10
After execution of IAC	+ 6543 2 10	+ 0 12 3456

Timing: IAC is a class 2 command. The sector address has meaning only in terms of sequence tagging (providing a transfer). The line address may be any number. The sector address, however, for minimum execution time (24 microseconds) must be $a + 1$, where a is the location of the INTERCHANGE A AND C command. The next command to be executed, under sequence tagging, will be taken from $a + 2$.

The contents of the B register are loaded into the C register, and the contents of the C register are loaded into the B register. These operations occur simultaneously; therefore no information is lost.

Example:

	(B)	(C)
Before execution of IBC	+2043177	+0021701
After execution of IBC	+0021701	+2043177

Timing: IBC is a class 2 command. (For further description, see IAC, 01, which is similar to IBC.)

The contents of the A, B, and C registers are simultaneously rotated in the following fashion: the contents of C are placed in B; the contents of B are placed in A; and the contents of A are placed in C.   No information is lost.

Example:

	(A)	(B)	(C)
Before execution of ROT	+ 1205721	+ 6201530	- 3170024
After execution of ROT	+ 6201530	- 3170025	+ 1205721

Timing: ROT is a class 3 command; 36 microseconds is the minimum execution time.   Although the sector address has no meaning in terms of execution of the command, for optimum programming, the address $a + 1$ is required, where a is the location of the ROT command.   This addressing, in conjunction with the sequence tag, obtains a minimum execution time (36 microseconds).   The next command will be executed from $a + 3$.   The line address may be any number.   As in all other commands in which sector address has no meaning in terms of command execution, ROT may be used to provide a transfer by use of sequence tagging.

LDA   Load A   (05)

The A register is cleared and the contents of M, the effective address, are read
into the A register. The previous contents of A are destroyed: the contents of
M are not affected.

LDB   Load B   (06)

The B register is cleared and the contents of M, the effective address, are read
into the B register. The previous contents of B are destroyed; the contents of
M are not affected.

LDC   Load C   (04)

The C register is cleared and the contents of M, the effective address, are read
into the C register. The previous contents of C are destroyed; the contents of
M are not affected.

Timing: LDA, LDB, and LDC are class 2 commands. To obtain minimum exe-
cution time (24 microseconds), the operand which is to be loaded into the regis-
ter must be located in the next sector after the command (α + 1), but not neces-
sarily in the same line, and the command must have a sequence tag of one. The
next command to be executed will be taken from α + 2, where α is the location
of the load command.

Both the A and B registers are cleared. The contents of M, the effective address, are read into the B register; the contents of M + 1 are read into the A register. The contents of M and M + 1 are not affected.

Timing: LDP is a class 3 command. To obtain minimum execution time (36 microseconds), the operand must be stored in $a + 1$ and $a + 2$, where LDP is located in a, in any line. Sequence tagging under these circumstances results in the next command being executed from $a + 3$.

Usage: This command, along with the other double precision commands, provides double precision arithmetic capacity within the command structure of the PB 250. Furthermore, in terms of data handling, it is often convenient to pick up or store two consecutive words which are not a single number but are two separate units of information. The LDP command reduces the number of memory accesses necessary in a program.

Some discussion of double precision is in order. A double precision number consists of two words, or 44 bits. Commands functioning in the double precision mode will operate on two words and treat A and B as one register, where A is the Most Significant Word (MSW) and B is the Least Significant Word(LSW).

Double precision numbers must be stored in consecutive words; the effective address is the lower-ordered address. For example, if the specified memory location is 03404, the double precision number is stored in memory locations 03404 and 03504. Location 03404 contains the Least Significant Word (LSW), while 03504 contains the Most Significant Word (MSW).

STA   Store A   (11)

The contents of the A register are stored in M, the effective address. The previous contents of M are destroyed; the contents of the A register are not affected.

STB   Store B   (12)

The contents of the B register are stored in M, the effective address. The previous contents of M are destroyed; the contents of the B register are not affected.

STC   Store C   (10)

The contents of the C register are stored in M, the effective address. The previous contents of M are destroyed; the contents of the C register are not affected.

Timing: STA, STB, and STC are class 2 commands. To obtain minimum execution time (24 microseconds), the contents of the register must be stored in the next sector after the command ($a + 1$), but not necessarily in the same line, and the command must have a sequence tag of one. The next command to be executed will be taken from $a + 2$, where a is the location of the store command.

$A \to M+1$
$B \to M$

This command operates on both the A and B registers. The contents of the B register are stored in M, the effective address; the contents of the A register are stored in M + 1. For example, if the specified address is 00004, the contents of B are stored in 00004 and the contents of A are stored in 00104. The previous contents of A and B are not affected; the previous contents of 00004 and 00104 are lost.

Timing: STD is a class 3 command.

The contents of M, the effective address, are algebraically added to the contents of the A register. This sum replaces the contents of A; the contents of M are unaffected. Overflow occurs when (A) and (M) initially have like signs and the result in A has a different sign.

Example: The command 011 1403; is executed. The contents of line 3, sector 011, are + 0210416.

	(A)	(01103)
Before execution of ADD	+0143115	+0210416
After execution of ADD	+0353533	+0210416

Timing: ADD is a class 2 command. To obtain the minimum execution time (24 microseconds), the operand which is to be added to (A) must be located in the next sector after the command, but not necessarily in the same line, and the command must have a sequence tag of one. The next command to be executed will be taken from a + 2, where a is the location of the ADD command.

Usage: Reference should be made to the discussion of 2's complement arithmetic in Appendix A prior to coding arithmetic problems for the PB 250.

The contents of M, the effective address, are algebraically subtracted from the contents of the A register.   The result replaces the contents of A; the contents of M are unaffected.   Overflow occurs when (A) and - (M) initially have like signs and the result in A has a different sign.

Example: The command   125 1507;   is executed. The contents of line 7, sector 125, are + 02 31 23 4.

	(A)	(12507)
Before execution of SUB	+ 6 120 134	+ 02 31 23 4
After execution of SUB	+ 5666700	+ 02 31 23 4

Timing: SUB is a class 2 command.

The contents of the word pair starting at M, the effective address, are algebraically added to the contents of the combined A and B registers. This sum replaces the contents of A and B; the word pair beginning at M is not affected. Position 0 of the B register does not act as a sign; but is part of the magnitude of the number, and any carry from position 0 of B propagates into position 21 of A. Overflow occurs when (A) and (M+1) initially have like signs and the result in A has a different sign. The double precision word in memory starts with (M + 1), where (M) represents the least significant part of the double precision number.

Example: The command 002 1602; is executed. The contents of line 02, sector 003, are + 1210456. The contents of line 02, sector 002, are 73120604 (11101100101000011100001).

	(A)	(B)	(003)	(002)
Before execution of DPA	+0124471	31425000	+1210456	73120604
After execution of DPA	+1335150	24545604	+1210456	73120604

Timing: DPA is a class 3 command. To obtain the minimum execution time of 36 microseconds, the operand which is to be added to (AB) must be located in the next two sectors after the command, but not necessarily in the same line and the command must have a sequence tag of one. The next command to be executed will be taken from $a + 3$, where a is the location of the DPA command.

Usage: The DPA command may be used to accumulate a double precision sum, where six decimal digits are not sufficient in an arithmetic computation. Another use occurs when it is certain that the sum in B will not overflow to A; two separate sums may then be accumulated, one in A and one in B. ADD may be used to add to (A), while DPA may be used to add to (B), where the most significant word to be added to (AB) consists of all zeros. A further use of DPA is to

round a positive double precision number in (AB) to a single precision number

in A. The number to be added to (AB) should appear as follows:

$$a \qquad = \ -0000000$$
$$a \ + 1 \quad = \ +0000000$$

The contents of the word pair starting at M, the effective address, are algebraically subtracted from the contents of the combined A and B registers. The result replaces the contents of A and B; the word pair at M is not affected. Position 0 of the B register does not act as a sign, but is a part of the number, and any carry from position 0 of B propagates into position 21 of A. Overflow occurs when (A) and -(M+1) initially have like signs, while the result in A has a different sign. The double precision word in memory starts with (M+1); (M) represent the least significant part of the double length number.

Example: The command 113 1705; is executed. The contents of line 5, sectors 114 and 113 are, respectively, +0124471 and 31425000.

	(A)	(B)	(114)	(113)
Before execution of DPS	+1210456	73120604	+0124471	31425000
After execution of DPS	+1063765	41473604	+0124471	31425000

Timing: DPS is a class 3 command.

The address field of the NORMALIZE AND DECREMENT command is not used to specify the location of an operand, but contains an address number, N, which specifies the first sector following the completion of execution. In executing this command, the (AB) are shifted left until one of two conditions is met:

1) $(A)_0 \neq (A)_1$; i.e., the contents of A, position 0, do not equal the contents of A, position 1.

2) (AB) has been shifted S positions (where S is selected by the programmer).

The line address should not have a one in position 16 (see description of NOR command). The (C) are decremented by one for each position shifted. Position 0 of A does not move, but position 0 of B takes part in the shifting. The vacated positions of B are filled with zeros. The programmer should select S large enough so as not to inhibit proper normalization. S is used in determining N in the following manner:

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8 .$$

Example: The command 071 2000; is located in sector 015 of line 02.

Before execution of NAD	+ 0012461	34105614	+ 0000010
After execution of NAD	+ 5230560	42706000	+ 0000000

Timing: NAD is a class 1 command. If a sequence tag of one is used, the next command is read from N. With a sequence tag of zero, the next command is read from $\alpha + 1$, where α is the sector location of the NAD command.

Usage: This command may be used in "floating" a fixed-point number to obtain a normalized floating point representation. Choosing S equal to $53)_8$

allows for normalizing every possible number in AB, but still terminates the
operation if (AB) equal zero.   If normalization is accomplished before N time,
the command is executed as a NOP (24) for the remaining sectors.   Note that
a shift of zero positions cannot be accomplished by any of the shifting commands.

The address field of the NORMALIZE command is not used to specify the location of an operand, but contains an address, N, which specifies the first sector following completion of execution. In executing this command, the (AB) are shifted left until one of two conditions is met:

1) $(A)_0 \neq (A)_1$

2) (AB) has been shifted S positions, where S is selected by the programmer.

The line address must have a one in position 16. (See description of NAD command.) The (C) are not affected by execution of NOR. Position 0 of A does not move, but position 0 of B takes part in the shifting and moves from 0 of B into 21 of A, etc. The vacated positions of B are filled with zeros. The programmer should select S large enough so as not to inhibit proper normalization. S is used in determining N in the following manner:

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8$$

Example: The command   071 20 10;   is located in 0 1502.

	(A)	(B)
Before execution of NOR	- 7731245	32001420
After execution of NOR	- 3124532	00142000

Timing: NOR is a class 1 command. If a sequence tag of one is used, the next command is read from N. With a sequence tag of zero, the next command is read from $a + 1$, where a is the sector location of NOR.

Usage: Choosing $S = 53)_8$ allows for normalization of every possible number in AB, but still terminates the operation if (AB) equal zero. If normalization is accomplished before N time, the command is executed as a NOP (24) for the remaining sectors.

The (AB) are shifted left for S positions, S being determined by the programmer. The (C) are decremented by one for each position shifted. Bits shifted past position 1 of A are lost and zeros fill the vacated positions of B. Position 0 (the sign) of A is not moved, but position 0 of B takes part in the shifting. The line address of this command should not have a one in position 16. (See description of SLT command). The sector address field of this command is not used to specify the location of an operand, but contains an address, N, which is determined by:

$$N)_8 = \text{Sector location of the command })_8 + S)_8 + 1)_8 .$$

Example: The command 021 2100; is located in line 3, sector 015.

	(A)	(B)	(C)
Before execution of LSD	- 1532104	36124104	+0000007
After execution of LSD	- 5321043	61241040	+0000004

Timing: LSD is a class 1 command. The next command to be executed, when this command has a sequence tag of one, is the command located in N.

Usage: This command should be used only when it is desired to decrease (C) by 1 for each position shifted left. It is important to remember that the sign position of A does not participate in the shifting. Note: $S \geqslant 53)_8$ results in setting $(A)_{1-21}$ and $(B)_{0-21}$ equal to zero.

The (AB) are shifted left for S positions, S being determined by the programmer. The (C) are not affected by this command. The line address of this command must have a one in position 16 (see description of LSD command). Bits shifted past position 1 of A are lost, and zeros fill the vacated positions of B. Position 0 of A is not moved (does not participate in the shifting), but position 0 of B does participate in the shifting. The sector address of this command is not used to locate an operand, but contains an address, N, which determines the length of the shift.

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8 \, .$$

Example: The command 021 2110; is located in line 03, sector 015.

	(A)	(B)
Before execution of SLT	-1532104	36124104
After execution of SLT	-5321043	61241040

Timing: SLT is a class 1 command. The next command to be executed, when this command has a sequence tag of one, is the command located in N.

Usage: This command may be used when it is desired to shift left without disturbing (C). The sign position of A does not participate in the shifting, and $S > 53)_8$ results in setting $(A)_{1-21}$ and $(B)_{0-21}$ equal to zero.

The (AB) are shifted right for S positions, S being determined by the programmer.
The (C) are incremented by one for each position shifted. The bit in the sign
position of A is copied into the vacated positions of A. Bits shifted past position
21 of B are lost. Position 0 (the sign) of A is not moved, but position 0 of B takes
part in the shifting. The line address should not have a one in position 16. (See
description of SRT command.) The address field of this command is not used to
specify the location of an operand, but contains an address number, N, which is
determined by:

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8 .$$

Example: Command 021 2200; is located in sector 015 of line 03.

	(A)	(B)	(C)
Before execution of RSI	-3120456	47217030	+0000000
After execution of RSI	-7312045	64721700	+0000003

Timing: RSI is a class 1 command.

Usage: Use RSI only when it is desired to shift (AB) right and to increment
the C register. (when C register incrementing is undesirable, see description
of SRT command.)

The (AB) are shifted right S positions, S being determined by the programmer. The (C) are not affected.   The bit in position 0 of A (sign position) is copied into the vacated positions of the A and B registers.   Bits shifted past position 21 of B are lost.   Position 0 (sign position) of A is not moved but position 0 of B takes part in the shifting.   Note: The line address of this command must be such that bit position 16 contains a one.   (See description of RSI command.) The sector address field of this command is not used to specify the location of an operand, but contains an address number, N, which is determined by:

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8 \ .$$

Example: The command 200 2210; is located in line 2, sector 171.

	(A)	(B)
Before execution of SRT	- 3177204	21643104
After execution of SRT	- 7731772	04216430

Timing: SRT is a class 1 command.

Usage: This command should be used when it is desired to shift (AB) right without affecting the (C).   (If incrementing the C register is desirable, see description of RSI command.)

The (AB) are shifted right and the (C) are incremented by one for each position shifted. The operation continues until one of the two conditions is met:

    1) $(C) \geqslant 0$

    2) (AB) are shifted S positions, where S is selected by the programmer.

The bit in the sign position of A is copied into the vacated positions of A. Position 0 (the sign) of A is not moved, but position 0 of B takes part in the shifting. S should be so selected as not to inhibit the scaling. The line address of this command should be zero. The sector address field of this command is not used to specify the location of an operand, but contains an address number, N, which is determined by:

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8 .$$

Example: The command 004 2300; is located in 00002.

	(A)	(B)	(C)
Before execution of SAI	+1231046	21320040	-7777500
After execution of SAI	+0123104	62132004	-7777503

Timing: SAI is a class 1 command. If sequence tagging is used with the command, the next command to be executed will be taken from N, even if condition (1), above, is obtained before N sector time.

Usage: This command can be used in "fixing" floating point numbers at a particular scale factor. If (C) become $\geqslant 0$ before N time, the command is executed as a NOP (which, in this case, will have an op code number of 27) for the remaining sectors.

This command causes the computer to continue in the regular command sequence. Memory and registers are not affected.

Timing: NOP is a class 1 command.   Sector address has meaning only in the event that a maximum operation speed is to be obtained.   Optimum programming requires a sequence tag of one and a sector address of $a + 2$, where NOP is located in a .   The next command to be executed will come from $a + 2$.   Line address may be any number.   NOP may also function as a transfer to β , when the sector address of the NOP command is β (β must be in the same line as NOP).

This command interchanges information in the line designated by the line address, with the information in the A register. The interchange starts in the sector following the IAM command and continues up to, but not including, the address sector number. This command results in a one-word precession of the information in the designated line. The information originally in the A register is entered into the first sector and is replaced by the information in the last sector.

Example: The command 0 15 2503; is located in sector 0 12 of line 2.

	(A)	(01303)	(01403)
Before execution of IAM	+3214071	-5377210	+3246002
After execution of IAM	+3246002	+3214071	-5377210

Timing: IAM is a class 1 command.

Usage: This is a very convenient way of manipulating sector sequential data in memory without modifying addresses. In effect, the designated sectors and the A register function, temporarily, as a special line. Each time IAM is executed, a stepping of data takes place as shown below. Note: a is the sector location of the IAM command, but is not necessarily in the same line as $a + 1$, a +2, etc., and $a + N + 1$ is the IAM sector address.

Location	Initial Contents	After 1st IAM	After 2nd IAM
A register	X_a	X_n	X_{n-1}
a + 1	X_1	X_a	X_n
a + 2	X_2	X_1	X_a
.	.	.	.
.	.	.	.
.	.	.	.
a + N -1	X_{n-1}	X_{n-2}	X_{n-3}
a + N	X_n	X_{n-1}	X_{n-2}

This command transfers information from the effective line address to line 07. The transfer begins in the sector following the MLX command and continues up to, but not including, the sector address.

Timing: MLX is a class 1 command; timing is similar to that for MCL (71).

Usage: This command should be studied in conjunction with MCL (71). It is to be noted, that both of these commands, though similar, have certain significant differences. MCL moves an entire command line, or any part of a command line in which the MCL is actually located, into another line. MLX moves some specified line, not necessarily the one in which it is located, or part thereof, into line 7; thus, in the case of a machine in which subroutines are stored in lines 10, 11, etc., it may be desirable to move these subroutines into line 7 for execution. This can be accomplished by using the MLX command. An entire line may be moved by giving the address $a + 1$, where the MLX command is located in a. It can be seen that both of these commands have a separate and important use in the PB 250. Judicious use of these commands provides an easy method for moving data from line to line, while preserving the same relative sector locations.

The argument must be in the combined AB registers. The (C) must be positive. The square root appears in B with the remainder in A. The C register takes part in this operation and its contents are replaced by the square root. The (C) will be the full root but will differ from the (B) in the least significant bit computed. If only A is loaded with the argument, (B) should be cleared or they may influence the least significant bit of the computed root.

The line address of this command should be zero. The sector address contains a number, N, which specifies the first sector location following the completion of the operation. The SQR command is a variable length operation, which permits the programmer to specify a quantity, S, which is the number of bits of the root that are to be developed. N is determined from S as follows:

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8$$

The argument, (AB), must be positive for this operation to be executed correctly. If $S = 21$, the full root is formed in B.

Example: The command 006 3000; is located in 36005.

	(A)	(B)	(C)
Before execution of SQR	+0100000	+0000000	+0000000
After exectuion of SQR	-5777776	+1000000	+1000001

Timing: The number whose square root is to be found should be at an even scale factor, 2Q. The result in the B register will be scaled at $Q + 21 - S$. For example, where $S = 21)_{10}$ and the (AB) are at $2Q = 20$, the result in B is scaled at $Q = 10$. If $S = 10$, and the (AB) are at $2Q = 20$, the result is in B at

Q = 21. Bit 11 of B will be a zero, and the result will be in bits 12 through 21;
bit 0 of C will be a zero, and nine bits of the result will be in bits 1 through 9.
SQR is a class 1 command.

The dividend is in the combined AB registers and the divisor is in the C register. The quotient appears in the B register, with a remainder in A. The line address of this command should not have a one in either positions 15 or 19. The sector address field contains an address, N, which specifies the first sector location following the completion of the operation. The DIV command is a variable length operation, which permits the programmer to specify a quantity, S, which is the number of bits of the quotient (including sign) to be developed. If S is 22, the full quotient is formed in $\underline{B}$, with a sign in $(A)_{21}$, and the unit bit in $(B)_0$. In case the divisor was greater than the dividend, the units bit will equal the sign bit, and the quotient will appear as a signed number in B only. N is determined as follows:

$$N)_8 \quad \text{Sector location of the command})_8 + S)_8 + 1)_8$$

Example: The command 027 3100; is located in 00003.

| Before execution of DIV | +0700000 | +0000000 | -7100000 |
| After execution of DIV | -6200001 | +7777777 | -7100000 |

This is a divide with S = 22. The last bit of A is the sign of the quotient, which is negative. In canonical form, the quotient is -0000000, and the remainder is +0000000.

Timing: DIV is a class 1 command. If a sequence tag of one is used, the next command is executed from N.

Usage: 1) If the dividend is scaled at Q (a), and the divisor at Q (b), then the quotient is scaled at Q $\left[a - b + 22 - S \right]$.

2)   The machine remainder is scaled at Q b-1 . The corrected remainder
will be scaled at Q (b).

3)   The binary point of the quotient is preceded by the unit bit and sign, and
is succeeded by the 1/2 bit, 1/4 bit, 1/8 bit, etc. Bits to the left of the sign bit
are not cleared.

Sign Bit   Units Bit   1/2 Bit

| | | ± | 1 | 1/2 | 1/4 | 1/8 | . | . | . | | |

Radix Pt.
QUOTIENT

In case the divisor is, in absolute value, greater than the dividend, then the
sign and unit bits are equal. Whenever the quotient is less than 2 in absolute
value, the unit bit reflects the true integral value. In case S = 22, the unit bit
is in $(B)_S$, and the sign of the quotient is in $(A)_{21}$. This will affect the least
significant bit of the remainder. For example, a full division of -1, scaled
at Q (0), by itself, gives a quotient of + 1 scaled at Q (0), i.e., a one in $(B)_S$
and zeros in $(A)_{21}$ and $(B)_{1-21}$.

4)   To obtain the undivided remainder at Q (b) from the machine remainder,
shift (A) right one position, using an LRS with bit 15 equal to ~~zero~~ one; if $(A)_S$ and
$(C)_S$ are now unequal, add (C) to (A). The undivided remainder is in the A
register.

5)   The canonical quotient is, in absolute value, less than, or equal to,
the theoretical answer. This implies that the sign of the canonical divided
remainder has the same sign as the quotient. In the PB 250, the quotient is
always less than, or equal to, the theoretical answer. Therefore, the divided

remainder will always be positive. For example, using integers scaled at the

right of the registers, -5 divided by + 3 is -1 with a divided remainder of -2/3

in canonical form. In the PB 250, a quotient of -2 and a divided remainder of

+ 1/3, is obtained which is mathematically correct. In the case of a negative

quotient, the quotient and undivided remainder must be altered if canonical

form is desired. Note that the quotient need only be corrected in the least sig-

nificant bit position. Therefore, for most purposes, the machine quotient is

sufficiently accurate.

6) The correction to canonical form, which is described in (7),

can be avoided if the original dividend and divisor are both positive, i.e., if

one attaches the sign to the quotient and remainder after the division takes

place. The correction described in (8) must be applied in either case.

7) To obtain an answer in canonical form, the quotient is altered

by adding a (+1) in bit position 21 if the quotient is negative. Table 2-1 shows

how to go directly from the uncorrected machine remainder to the canonical

undivided remainder. First shift (A) right one place using an LRS command

with bit 15 equal to zero. Then add or subtract (C), or leave (A) unchanged

according to Table 2-1. This depends on the signs $(A)_S$, $(B)_S$, and $(C)_S$

after the shift and before the quotient is corrected. The remainder will have

a scale of Q (b).

Table 2-1

DIVISION CORRECTION

$(C)_S$	$(A)_S$	$(B)_S$	Correction
+	+	+	none
+	+	-	-(C)
+	-	+	+(C)
+	-	-	none
-	+	+	none
-	+	-	+(C)
-	-	+	none
-	-	-	-(C)

8)   After the correction to canonical form, the quotient may be exactly one unit less than the answer, in absolute value. This will be reflected by:

a)   (remainder) = (divisor) if the quotient is positive.

b)   (remainder) = - (divisor) if the quotient is negative.

In these cases, the quotient should be increased or decreased by a (+1) in bit position 21, and the remainder set equal to zero.

The remainder is in the combined AB registers, and the divisor is in the C register. The quotient appears in the B register; the remainder appears in A. The line number of this command should have a one in position 19 and a zero in position 15. The sector address field contains an address, N, which specifies the first sector location following the completion of the operation. The DVR command is a variable length operation, which permits the programmer to specify a quantity, S, which is the number of bits of the quotient to be developed. The quotient has no sign. If S=22, the most significant bit will be in $(B)_0$. N is derived as follows:

$$N)_8 = \text{Sector location of the command})_8 + S)_8 + 1)_8.$$

Example: A 4, scaled at 24, is divided by 3, scaled at 21. The result, with S=21, should be 1 1/3, scaled at 4. The result after the DIV is shown, and then the result after saving the quotient, clearing the B register, DVR with S=22, and replacing the original quotient into the A register, giving a double precision result.

	(A)	(B)	(C)
Before execution of DIV	+ 0000000	– 0000000	+ 0000003
After execution of DIV	– 7777776	+ 0525252	+ 0000003
After execution of DVR and splicing	+ 0525252	– 2525252	+ 0000003

Timing: DVR is a class 1 command. If sequence tag of one is used, the next command is executed from N.

Usage: The DVR operates on an uncorrected remainder. Before performing the DVR, if maximum accuracy is desired, the quotient should be saved and the B register should be cleared. For maximum accuracy, the original DIV should

have used an S of 21, maximum.   This is because of the sign bit in $(A)_{21}$
when S = 22 (see DIV description).   The quotient of the DVR, with S = 22,
can be spliced to the quotient of the DIV.   In general, the quotient of the
DVR should be shifted left (22 - S) places before splicing it to the quotient
of the DIV.   The correction to the remainder, and the correction for can-
onical form, follow the procedure described in DIV, except that correcting
the quotient requires a DOUBLE PRECISION ADD (DPA) command of + 1
in the 43rd bit of the quotient.

The multiplier must be loaded into the B register and the multiplicand must be loaded into the C register. The computer clears the A register before multiplying, provided that the line address of the command does not have a one bit in position 15. The product appears in the combined AB registers; (C) are unaffected. The sign of the product and the 21 most significant bits of magnitude appear in the A register; the 22 least significant bits of magnitude appear in the B register.

The address field of the MULTIPLY command is not used to specify the location of an operand, but contains an address number, N, which specifies the first sector number following the completion of multiplication. The MULTIPLY command is a variable length operation and, as such, the programmer may specify a quantity, S, which is the number of bits, starting from the least significant end of the multiplier, B, to operate on the multiplicand, C. If the binary point is always considered to be to the right of the sign, and S is $22)_{10}$, or $26)_8$, then the full product is formed in A and B with the binary point to the right of the sign bit in A. Note that the sign of B is counted as a multiplier bit. If S is $23)_{10}$, or $27)_8$, one-half of the product is formed in A and B with the binary point to the right of the sign bit in A. N is determined from S in the following manner:

$$N)_8 = \text{Sector number of the command})_8 + S)_8 + 1)_8 .$$

Timing: MUP is a class 1 command. 12 microseconds are required to read the command; 12 S microseconds are required to carry out the command. In the event a sequence tag of 1 is used, the next command is executed from N.

Example: The command 037 3200; is located in 01003.

Before execution of MUP	irrelevant	+0000003	+0000004
After execution of MUP	+0000000	+0000030	+0000004

Usage: When $S = 26)_8$ is used, all the bits of the multiplier operate on all the bits of the multiplicand. Binary scaling follows the rule that the scale factor of the product equals the sum of the scale factors of the multiplier and the multiplicand. If the (B) are at $Q = 10$ and the (C) are at $Q = 17$, then the Q of the product is 27. (The binary point is between bit positions 5 and 6 of the B register.) When a product which is less than full length is formed (which reduces the time required to execute a MUP), S bits of the B register are combined with the 22 bits of the C register to form a product which occupies $S + 21$ significant bits of the combined AB registers, starting with the sign position of A. For example, if the multiplier is known to be always no more than 9 bits plus sign, S would equal $12)_8$, and the product would appear as shown:

Sign of   Magnitude of
Product   Product
The bits which are originally in $(B)_{0-11}$ are moved to $(B)_{10-21}$, with the bit in $(B)_{10}$ repeated in $(B)_9$.

The (AB) are shifted right, S positions, S being determined by the programmer. The (C) are unaffected by the execution of this command. After (AB) are shifted right one bit position, the A register is cleared; thus, if $S \geqslant 2$, zeros are shifted into B after sector time $a + 1$, where a is the location of the SRB command. Bits enter $(B)_0$ from $(A)_{21}$; bits shifted past position 21 of the B register are lost. The line address of this command must have a zero in position 15 (see description of LRS command). The sector address field of this command is not used to specify the location of an operand, but contains an address number, N, which is determined by:

$$N)_8 = \text{The Sector location of the command})_8 + S)_8 + 1)_8 .$$

Example: The command 004 3300; is located in sector 000 of line 3.

	(A)	(B)
Before execution of SBR	10101111	01011001
After execution of SBR	00000000	00101011

Timing: SBR is a class 1 command.

The (AB) are shifted right S positions, S being determined by the programmer. The (C) are unaffected by the execution of this command. LRS differs from RSI in that the sign position of A, $(A)_0$, participates in the right shift. The parity bit is copied into the sign position of A, and, if shifting continues, it is then copied into the vacated positions of AB. Bits shifted past position 21 of B are lost. The line address of this command must have a one in position 15. The sector address field of this command is not used to specify the location of an operand but contains an address number, N, which is determined by:

$$N)_8 = \text{The sector location of the command})_8 + S)_8 + 1)_8 .$$

Example: The command 012 3320; is located in sector 005 of line 07.

	(A)	(B)
Before execution of LRS	-2310724	76124500
After execution of LRS	XX514435	23705224

Note: XX are bit positions 0 through 3 of the A register, which are filled with the parity bit.

Timing: LRS is a class 1 command.

TAN   Transfer if A Negative   (35)

If the contents of the A register are negative, the computer will take its next
command from the effective address, which may be in any command line. If
the contents of A are not negative, the next sequential command is executed.
A sequence tag of zero is required.

TBN   Transfer if B Negative   (36)

If the contents of the B register are negative, the computer will take its next
command from the effective address, which may be in any command line. If
the contents of B are not negative, the next sequential command is executed.
A sequence tag of zero is required.

TCN   Transfer if C Negative   (34)

If the contents of the C register are negative, the computer will take its next
command from the effective address, which may be in any command line. If
the contents of C are not negative, the next sequential command is executed.
A sequence tag of zero is required.

Timing: TAN, TBN, and TCN are class 4 commands, therefore all operate
under the same timing considerations. If the register referred to is negative, the
next command is read from the line and sector number specified by the command.
If the register is not negative, the command directly following the transfer of
control command is read. A conditional transfer, where the condition is not met,
thus requires no execution time. The execution time, when control is transferred,
is 12 microseconds per sector, for the interval between the transfer of control and
the next command to be executed.

Usage: A sequence tag of one with either TAN, TBN, or TCN results in an
unconditional transfer.

2-42

The computer will take its next command from the specified address, which may be in any command line. For an unconditional transfer to be executed, a sequence tag of one must be present.

Timing: TRU is a class 4 command. The execution time is 12 microseconds to read the transfer command itself, plus 12 microseconds per sector for the interval between the transfer of control command and the next command to be executed. Optimum transfer location is $a + 2$, where a is the location of the TRU command.

Usage: The TRU command functions as a TBN when the sequence tag of one is not present.

Starting from the right, each position of M, the effective address, is checked. If the position contains a zero, the corresponding position in A is unaffected; if the position contains a one, the corresponding position of A is changed so that it is the same as the bit written to its immediate right. The (M) are unaffected. All 22 positions of A and M take part in this operation.

Example:

	(M)	(A)
Before execution of EBP	111000111000	010101010001
After execution of EBP	111000111000	111101000001

Timing: EBP is a class 2 command.

Usage: (M) should not have a one in position 21, for this would "extend" the guard bit. This command can be used to determine the presence or absence of a one in any bit position of the A register, by extending that bit to the sign position of the A register and then performing a TAN to provide a transfer of control if there was a one in the position tested. EBP may also be used to extend a sign located in any other bit position into position 0.

The GRAY TO BINARY command sends the binary representation of a Gray-coded number in A to A.   The result in A is correct only if the sign of the A register is positive.   If the sign is negative, the one's complement of the result in A should be used.   This command will also aid in parity tests on input data.   If, after this command is given, the sign of A is negative, then A originally had an odd number of ones in bit positions 1 through 21.

Where the original bits in A are A_{21}, A_{20}, A_{19}, etc. , in bit positions 21, 20, 19, etc. , the GRAY TO BINARY command produces bits B_{21}, B_{20}, B_{19}, etc. , in A, where

$$B_{21} = 0$$

$$\text{and} \quad B_i = 1 \text{ if } \left[\sum_{k=i+1}^{21} A_k \right] \text{ is odd.} \quad 0 \leqslant i \leqslant 20$$

The theoretically correct values for the GRAY TO BINARY conversion are

$$B_0 = 0$$

$$\text{and} \quad B_i = 1 \text{ if } \left[\sum_{k=1}^{i} A_k \right] \text{ is odd.} \quad 0 \leqslant i \leqslant 20$$

This command either gives the correct result for all bits or the one's complement of the correct result.

Example: (A)

    Before execution of GTB   00101110   (52 in Gray code)

    After execution of GTB   00110100   (52 binary)

, Timing: GTB is a class 2 command.

Usage: When used to check parity, an even number of ones in the A register
will produce a zero in position 0 of the A register (A sign positive). An odd
number of ones in the A register will produce a one in position 0 of A (A sign
negative).

When used to convert Gray code to binary (a common requirement when analog
information has been digitized), the GTB should always be followed by a TAN
command. The address of the TAN should lead to a sequence whereby the one's
complement of (A) may be found. If the (A) are positive, this need not be
completed as the correct result will have been obtained.

A one is placed in each of those bit positions of B where there are ones in the corresponding positions of both C and M, the effective address. Zeros are placed in all other positions of B. (C) and (M) are not affected. All 22 positions of M, B, and C take part in this operation.

Example:

	(M)	(C)	(B)
Before execution of AMC	1100	1010	irrelevant
After execution of AMC	1100	1010	1000

Timing: This is a class 2 command. The optimum address is $a + 1$; sequence tagging under these circumstances results in the next command coming from $a + 2$.

Usage: This command produces the logical sum of the contents of the C register and the contents of memory, and places this logical sum in B. The most common use would be in applications requiring AND logic. An instance would be where corresponding bit positions in a group of words, each word representing elements of an ensemble, represent the presence (1) or absence (0) of a quantity. It is desired to know which quantities are present in all elements of the ensemble. This can be obtained by a series of AMC commands on the various elements (words) of the ensemble.

CLA   Clear A   (45)

Each bit in the A register is set to zero, including the sign position.

CLB   Clear B   (43)

Each bit in the B register is set to zero, including the sign position.

CLC   Clear C   (44)

Each bit in the C register is set to zero, including the sign position.

Timing: CLA, CLB, and CLC are class 2 commands.   Although the sector
address has no meaning, timing considerations for optimization require that the
sector address be the next sector after the command $(a + 1)$, and that the com-
mand have a sequence tag of one.   The next command to be executed will then
be taken from $a + 2$, where a is the location of the clear command.   These com-
mands effectively provide "transfer and clear" when sequence tagging is em-
ployed and the sector address of the command is $\beta - 1$, when it is desired to trans-
fer to β.

Symbolically, this command is MC OR $\overline{\text{MB}}$, with the result appearing in B. For each one in M, the effective address, the bit in the corresponding position of C is copied into B. For each zero in M, the bit in the corresponding position of B is preserved. All 22 positions of M, B, and C take part in this operation; (M) and (C) are not affected.

Example:

	(M)	(C)	(B)
Before execution of AOC	1111 0000	11 001 010	01011100
After execution of AOC	1111 0000	11 001 010	11 001100

Timing: AOC is a class 2 command.

Usage: This command effectively provides a means of inserting selected information from one word into another word. It is a convenient method of "packing" a word.

For each one in M, the effective address, a zero is put in the corresponding position in B.   For each zero in M, the bit in the corresponding position of B is preserved.   All 22 positions of M and B take part in this operation.

Example:

	(M)	(B)
Before execution of EXF	111000	110101
After execution of EXF	111000	000101

Timing: EXF is a class 2 command.

Usage: Selected positions of the B register may be zeroed out while all other positions are left unchanged.   Sometimes a word is divided into two or more fields (groups of consecutive bit positions), where each field has a distinct meaning.   This is called "packing" a word.   Thus, it is possible to edit the (B) and remove (zero out) unwanted fields from a packed word.

The Input Buffer is deactivated and all input devices are disabled from filling it.   The Indicating light of the Flexowriter, if on, is turned off.

Timing: DIU is a class 2 command.

Usage: This command is used to disconnect an input device, especially a fast device, after the input is complete and before another device is activated. DIU can also be used after the computer has "waited" for a period of time and not received an input;   for example, if the typewriter is activated and, after a certain period of time, no character is entered, the program can deactivate the keyboard and continue.

The Indicating light on the Flexowriter is turned on and the Input Buffer is activated to accept a character from the keyboard. After a key has been depressed, the Flexowriter sends a signal to the computer, which may be tested by a TES command having a line address of $36)_8$ to determine if the Input Buffer has been filled. Depressing a key also causes the light on the Flexowriter to go out. It is necessary to execute an RTK for each character to be read.

Timing: RTK is a modified class 2 command. Execution begins in sector $a + 1$, where a is the sector location of the command, and continues through the sector specified by the command. If β is the sector address, and a sequence tag of 1 is used, the next command will come from $\beta + 1$. If a sequence tag of 0 is used, the next command will come from $a + 1$.

Usage: RTK is always used when reading information from the typewriter keyboard. This information will be loaded into the buffer in 6-bit codes which may be loaded into the A register with an LAI command.

This command functions exactly as RTK except that instead of turning on the keyboard light and waiting for a key to be depressed, it causes the tape reader to read one frame of tape. Sine the paper tape reader has 8 columns, as many as 8 bits per frame may be punched on it and loaded to the Input Buffer by means of the RPT command. It is necessary to execute this command for each frame of tape read.

Timing: Like RTK, RPT is a modified class 2 command which starts its execution in $a + 1$ and continues through β , where a is the actual sector location of RTK and β is the sector address.

Usage: If an RPT command is given at the proper intervals, it is possible to keep the tape moving at 10 frames/second, which is the maximum input rate of the Flexowriter. (See Section IV for details on this operation.)

This command will cause the Input Buffer to be filled by a fast, special purpose unit. The PULSE TO SPECIFIED UNIT command is used to select, start, and stop these fast units. This command differs from the other read commands in that it is not self-disabling. The DISCONNECT INPUT UNITcommand must be used to terminate this operation deactivate the buffer.

Timing;   RFU is modified class 2 command. *

Usage: This command may be used for fast input devices that require the Input Buffer.

* see RTK (53) (p. 2-52) for explanation of modified class 2.

The capacity of the Input Buffer is any character up to eight bits. This command will load the contents of the Input Buffer into positions 14 through 21 of the A register under control of a Format Word, or "mask." Load A from Input Buffer always takes the Format Word from the specified sector and from the same line in which the LAI command is located. The sector location of the "mask" is specified by the sector address of the LAI command. Positions 0 through 13 of A may be affected if the mask contains ones in positions 0 through 13. The Format Word functions as follows: in those positions of the word where there are ones, the corresponding bit positions of the Input Buffer register are transferred to the corresponding positions of A. No other positions of A are altered. After the transfer of information to A, the Input Buffer is cleared.

Example:

	(A)	(IB)	(Mask)
Before execution of LAI	+0124000	104	+0000377
After execution of LAI	+0124104	000	+0000377

Timing: LAI is a class 2 command.

Usage: This command is always used when information is input to the PB 250 by way of the Input Buffer. Another use occurs if the mask contains all ones and is located in sector 376 of the appropriate line; if the Input Buffer has been previously cleared, zeros will be inserted in all positions of A. Selective insertion of zeros in A is possible by varying the mask, but the mask must be in sector 376 of the appropriate line.

The contents of A (the effective address) are compared with the contents of M and, if the two are identical, the Overflow switch is turned on. If not, the Overflow switch will be turned off. In either case, the (A) and (M) are unaltered and command execution continues in the regular manner. All 22 positions of A and M are compared. The description of the TOF command should be studied in conjunction with the CAM command.

Timing: CAM is a class 2 command.

Usage: The following sequence effectively provides a transfer on zero in A:

Location	Contents	Remarks
a	CAMa + 1, S	Must be sequence tagged.
a + 1	00000 . . .	Location contains all zeros.
a + 2	TOF β	Transfer if (A) = 0, where $\beta \neq a + 3$.
a + 3	- - -	Program continues here if (A) $\neq$ 0.

The eight bits of the Input Buffer are set to zero. Execution will occur during the sector address time.

Timing: CIB is a class 2 command.

Usage: This command is used when it is necessary to clear out old or un-wanted information from the Input Buffer before accepting new data. The use of CIB as an in-line transfer is the same as for other clear commands. Although LAI clears the Input Buffer each time it is executed, extraneous information will get into the buffer when the sequence counter is reset to sector 0 of line 1 by the I key (I goes into the input buffer), or when single-stepping through a program by means of the C key (C goes into the input buffer). The input buffer, therefore, should be cleared prior to each use.

This command causes a single character up to eight bits to be sent to a specified output unit. The character is incorporated into the command and occupies bit positions 12 through 19 of the word; these bits are bits 12 through 14 of the op code field and bits 15 through 19 of the line number. The X in the numbered code (6X) is thus determined by the output character.

The unit to which the character is sent is specified by the command line in which the WOC command is located. Line 05 specifies the typewriter; line 06 specifies the punch; and line 00 specifies certain devices such as magnetic tape or a high-speed punch.

In order to provide the output device with a signal of sufficient duration to initiate operation, a delay number must be loaded into the C register before the execution of WOC. This number is decremented by one for each sector time after the command until the number goes negative. When the (C) go negative, the WOC command behaves as all other class 1 commands and terminates when the sector specified, β , is reached.

The signal to the output device is therefore sustained from $a + 1$, where a is the location of WOC, until β , the specified sector, appears for the first time after the C register becomes negative. The (C) continue to be decremented, after they become negative, until the command terminates.

If the C register is initially negative, the output signal will be sustained only form $a + 1$ to β; however, (C) will still be decremented.

Timing: WOC is a modified class 1 command and, as such, will cause the next command to be taken from the sector specified if the sequence tag is 1.

2-58

Usage: All output, except that controlled by the BSO or PTU commands, must be in the form of WOC commands.   When forming WOC commands in a program, the output character is offset from the right end of the word by two bits, and the index tag is generally zero.   The WOC configurations for the Flexowriter codes are as follows:

Table 2-2

FLEXOWRITER CONFIGURATIONS FOR WOC COMMANDS

Alphabetical Characters (available in both upper and lower case)		Numerical and Special Characters			Control Characters	
		Upper		Lower		
A 6101	N 6005	)	6100	0	UC	6132
B 6102	O 6006	‖	6001	1	LC	6134
C 6123	P 6027	√	6002	2	Tab	6136
D 6104	Q 6030	=	6023	3	C/R	6116
E 6125	R 6011	⌐	6004	4	Stop	6013
F 6126	S 6122	⌐	6025	5	Delete	6137
G 6107	T 6103	⌂	6026	6	Space	6020
H 6110	U 6124	&	6007	7		
I 6131	V 6105	*	6010	8		
J 6021	W 6106	(	6031	9		
K 6022	X 6127	?	6036	+		
L 6003	Y 6130	——	6037	—		
M 6024	Z 6111	:	6120	;		
		"	6033	'		
		,	6133	,		
		.	6113	.		
		/	6121	$		

This command produces a specified combination of signals on five output lines and an "activate" signal on a sixth line. These signals are used to start and stop equipment external to the computer. The line address of the PTU command specifies the combination of signals, while the sector address defines the first sector following execution. The activate signal is presented in the sectors between the command location and the sector address.

Timing: PTU is a class 1 command. The PTU signal will be held "on" until β comes up, where β is the sector address of the PTU command.

Usage: The following sequence of commands may be useful when desiring to hold a PTU "on" for $\sim$ 3N milliseconds:

Location	Contents	Seq. Tag	Remarks
α	LDC α + 1	S ⎫	Initialize counter
α + 1	Count	⎬	
α + 2	LSD α + 4	S ⎫	PTU is "down" 36 μsec
α + 3	not used	⎬	each cycle
α + 4	TCN α + 6	⎭	
α + 5	PTU α + 2	S ⎫	Execute
α + 6	Continue	⎬	

Such a sequence can be used to condition the setting of relays external to the computer.

The contents of the first word following the MCL command, and all subsequent words on that line up to, but not including, the address sector number, are copied into the corresponding sector positions of the effective line address.

Example: The command 010 7104; is located in 37006. When this command is executed, the information in line 6, beginning with sector 371, and continuing through sector 007, is moved to the corresponding sectors of line 4. The information which was originally in line 6, sectors 371 through 007, remains as before, but now this information has been duplicated in line 4, sectors 371 through 007.

Timing: MCL is a class 1 command. In this class of commands, the sector number of the command is used to designate the first sector number in which execution of the command is discontinued. Thus, 12 microseconds are required for reading this command, and 12 microseconds per sector transferred are required for executing this command.

Usage: This command is a convenient way of moving entire lines of information, one line at a time. By giving as the sector address $a + 1$, a complete line is moved from its original location to a new location. This method provides a convenient means of initializing subroutines in which addresses are to be modified. (Also see the MLX command, 26, in this connection.)

The BLOCK SERIAL OUTPUT command operates in a manner which is effectively the reverse of the BLOCK SERIAL INPUT (73) command. That is, the information in the data line is shifted into the External Register (ER) whenever a one appears in the Format Block. Nothing is done with information in those positions of the data line which correspond to zero bits in the Format Word. For details of this command, reference is made to the description of the BLOCK SERIAL INPUT (73) command. Computer memory and registers are unaffected by this command.

Example: The command 01257204; is located in 01 002. All ones are stored in 01102.

	(01104)	(ER--22 bits)
Before execution of BSO	+1215702	+0000000
After execution of BSO	+1215702	+1215702

Timing: BSO is a class 1 command. (See BSI description for further information.)

Usage: BSO can be used to provide a fast output, with format control, to an External Register.

This command loads information directly into memory at the rate of 0.5 micro-seconds per bit. Input information is presented to the computer in the form of a series of bits, normally from some external shift register (ER). The shifting operation in the external register must be under computer clock control. A Format Block determines when a bit will be accepted from the input device. This Format Block is formed by the binary configuration of information contained in that portion of the command line which begins with the sector following the BLOCK SERIAL INPUT command and continues up to, but not including, the sector address of the command. The information entering the computer will be loaded into the line specified by the line address of the command; it will occupy those positions of this line that correspond with one bits in the Format Block. Positions of this data line that correspond with zero bits in the Format Block will be loaded with zeros.

Example: The command 377S7305; is located in 37502. Location 37602 contains all ones. ER is the external register source from which information enters the computer.

	(37605)	(ER - - 22 bits)
Before execution of BSI	+ 0000000	+ 1234567
After execution of BSI	+ 1234567	+ 0000000

Timing: BSI is a class 1 command. The next command to be executed, when this command has a sequence tag of 1 (which it always should), will come from β, where β is the sector address. β will be the sector after the last sector of the mask.

Usage: The BSI and BSO commands provide a very fast and convenient method for communicating with an external register. In addition, formatting control is also provided. The most frequent use of these commands will come in computer systems work, where a high-speed buffer is used by the computer to communicate with equipment the computer is controlling.

An overflow results from generating a number too large for the capacity of the arithmetic registers, specifically from the ADD, SUBTRACT, DOUBLE PRE-CISION ADD, and DOUBLE PRECISION SUBTRACT commands. When an over-flow occurs, the Overflow switch is turned on. The command COMPARE A AND M will also turn the Overflow switch on if (A) are equal to (M), but turn off the Overflow switch if this is not true. After execution of the command SQUARE ROOT, the Overflow switch is turned off.

The TRANSFER ON OVERFLOW command will cause the computer to take its next command from the specified address (if the Overflow switch is on), and then turn off the switch. If the Overflow switch is off, the next sequential command is executed and the switch remains off. Transfer may be to any sector of any command line. A sequence tag of zero is required for conditional transfer. A sequence tag of one provides an unconditional transfer and turns the Overflow switch off.

Timing: TOF is a class 4 command. Therefore, in the event a transfer is not executed, control proceeds to the next command and the total time required is the 12 microseconds required to read this command. In the event control is transferred, execution time is 12 microseconds per sector for the interval between the TOF command and the command to which control is being trans-ferred, plus 12 microseconds to read the TOF command.

Usage: The TOF command should be studied in conjunction with the CAM command. It is the programmer's responsibility to see that the Overflow switch is off before executing a set of commands which are tested by a TOF.

This command will cause the computer to take its next command from the specified address upon sensing a signal from the source external to the computer. The nature of this signal is specified by the line address of the TES command. In the standard PB 250, line addresses 25 through 37 are used to specify the following input signals:

Lines 25-30:	Arbitrary input signals.
Line 31:	High-speed punch sync. signal
Line 32:	Magnetic tape gap signal
Line 33:	Magnetic tape reader clock input signal
Line 34:	Photo tape reader sprocket input signal
Line 35:	BREAKPOINT switch input signal.
Line 36:	Typewriter or paper tape reader "character input complete" signal.
Line 37:	"Typewriter not ready for an output character" signal.

Line numbers 00 through 24 will provide additional input selectors which may be obtained as options for additional arbitrary input signals. Since the line number of the address is reserved for signal specification, the effected transfer can be only to some sector in the same line as the TRANSFER ON EXTERNAL SIGNAL command.

Example:

Location	Op Code	Address
02206	TES	02736

If a transfer is effected, the computer will take the next command from location 02706. If no transfer is effected, the next command will be executed from 02306. The sequence tag should always be zero for this command.

Timing: TES is a class 4 command. When a signal is not present, the command directly following TES command is read and the total execution time is 12 microseconds. If control is transferred, execution time is 12 microseconds,

plus 12 microseconds per sector for the interval between the TES command and the command to which control is being transferred.

Usage: Use of this command is further described in Section IV, " Input/Output Techniques. " In general, the TES command acts as a " stoplight, " indicating whether input/output commands should be executed or delayed. If a TES is executed which refers to an input line not physically present on the computer, the transfer will take place.

III. STANDARDS AND PROGRAMMING TECHNIQUES

3.1 PROGRAMMING TECHNIQUES

3.1.1 Introduction

There are two basic methods of programming the PB 250; relatively non-optimized, and relatively optimized. The detailed techniques and optimization rules are given for most of the commands described in Section II.

Considered as a computer without any capabilities for optimizing programs, the PB 250 still has the same command structure, and presents only the problems of any serial, binary, single-address computer. In this frame of reference, commands are generally executed from sequential sectors, at a rate of approximately three milliseconds per operation.

Partial optimization, i.e., locating the operand for class 2 commands in the next sector after the command, wherever possible, is relatively simple. For example, if a constant is needed, it is prestored in the sector after the sector for which it is required. This basic optimization greatly increases the operation speed of the machine, but does not make the most efficient use of memory. More complex optimization techniques will provide high operation speed while at the same time using memory efficiently. The programming time will be expected to increase as the complexity of techniques is increased. Although the more complex programming methods result in more efficient machine operation, a point of "diminishing returns" will be reached. After this point, more programming time will not appreciably increase either computer operation speed or efficiency of memory usage.

3.1.2   Optimization Considerations

The traditional 1 + 1 address serial computer offers a variety of possibilities for optimizing a command. If the next command cannot be placed in the optimum location (often the next section after the last operand required), then the sector one further down may be chosen, etc. On the PB 250, however, no such gradation exists. The next command is either in the optimum location (generally immediately following the operand) or it is completely unoptimized and simply follows the current command (which is in a) by appearing in $a + 1$.

Paragraphs 3.2 and 3.3 describe the use of the fast line and show an example of the difference between an optimized and unoptimized PB 250 program. It is sufficient to state that the most effective way of using the fast line is as a fast access location for data frequently required during a computation, rather than as a means of storing a program to be executed. It is stressed that addresses which refer to the fast line are interpreted in exactly the same way as the addresses which refer to any of the long lines.

An important rule to remember for optimization is that memory accesses are always expensive in terms of program execution time. That is, the programmer should always think in terms of manipulating information in the A, B, or C registers, rather than storing and loading it back into these registers. Among the operations for manipulating information within the registers are the shifts (with or without affecting the C register), the register interchanges, the Rotate command, and the Merge A into C command (which can be used as a copy A into C if the C register is first cleared).

3.1.3   Special Techniques

One useful technique is the method of placing the two's complement (negative) of the (C) into A. This occurs under a one-sector multiplication, where

the B register has previously been loaded with a word whose last two bits (positions (20 and 21) are 01. All the variable length commands should be closely scrutinized by the programmer for possible special uses.

Another special technique consits of setting an internal switch by the use of RFU to turn the switch off, DIU to turn it on, and a TES $36)_8$ to determine whether the switch is on or off. Transfer will occur when the switch is on.

If additional externally operated controls are desired beyond the single BREAKPOINT switch on the Flexowriter, these may be furnished by using the surplus (unassigned) signal lines, together with external toggle switches. (See description of TES command.)

Any optimized program uses much more space in the computer than its unoptimized equivalent. However, these empty spaces do not have to be wasted. It is possible that at least one other optimized program can be interlaced with the original program in the available vacant sectors.

3.2   USE OF LINE 00

Line 00, the "fast access" line, provides fast access storage for 16 words. Any word placed in any sector of line 00 is read 16 times during each long line circulation time of 3072 microseconds. Thus, each word in line 00 is 16 times more accessible than a word stored in the long lines.

A number used repeatedly in a calculation can be stored in the fast line for ready availability. (See the Recirculation Chart in Appendix D.)

The following example illustrates the use of the fast line:

Sector	Line	Command	Remarks
023	06	┌─ 024S0500;	(F04)→(A)
024		│ Not Used	
025		└→ 042S1406;	(A)=(F04)+(04206)
026		│	
027		│	
030		│	
│		│	
│		│	
│		│	
042		Constant	
043		└→ 044S1100;	(A)→(F04)

A word is picked up from channel F04, a constant is added to it, and the sum is stored back into F04.

The programmer should be aware that optimization is possible only when reference is made to the proper sector of a channel. That is, an LDA command in 023, which is to pick up data from F04, must be sequence tagged and have a sector address of 024, not 004, 044, etc. If the sequence of commands in the previous example were written in the non-optimized modes, the execution time would be 3.072 milliseconds per command, or a total of 9.216 milliseconds. By optimization, the same computation is accomplished in 0.216 milliseconds.

Addresses referring to line 00 are not interpreted modulo $16)_{10}$, which is why the appropriate sector of a particular channel must be referenced for optimization purposes.

The fast line is extensively used in connection with such high-speed input/output devices as magnetic tape and photoelectric tape readers.

3.3 SAMPLE PROGRAMS

The sample problem may be stated as follows: Channel F03 is initially clear. X_i ($1 \leqslant i \leqslant 10$, $X \geqslant 0$) are stored in line 03, sectors 003 through 014. It is required to write a program which obtains the sum of these elements. $\left(\sum\limits_{1}^{10} X_i \right)$ and, in addition, replaces each X_i by $\dfrac{X_i + 100}{4}$. Overflow will not occur. The program should halt with line address 33)$_8$ and with $\sum\limits_{1}^{10} X_i$ stored in F03.

The optimized and unoptimized programs to perform the desired function are presented on the following two pages. These two example should be studied as a contrast in techniques. The unoptimized program requires over 300 milliseconds to execute; the optimized program requires only 30 milliseconds to execute.

3.4 PROGRAMMING CONVENTIONS

Certain conventions and techniques should be followed as a program is being developed. These conventions ensure that:

a)   Communications between programs is simplified.

b)   Routines can be adapted to a wide variety of problems.

c)   Necessary modifications can be implemented with the minimum amount of program rewrite.

3-7

d) Ease of understanding will be provided.

As previously described, the group of sectors in line 00 which simultaneously contain the same information, are called a channel. Line 00 channels are designated F00 through F17. For example, F00 refers to, collectively, locations 00000, 02000, 04000, 06000, 10000, 12000, 14000, 16000, 20000, 22000, 24000, 26000, 30000, 34000, and 36000.

Lines are referred to by their octal address, i.e., 00 through $77)_8$; sectors are also referred to in octal notation, i.e., 00 through $377)_8$.

Normally, the Index register, and F00 through F17, are available to any program or subroutine and must be preserved by the programmer before entering the subroutine, if these registers contain information which is to be used later in the main program.

Subroutines will generally be entered with the argument in the A register and the exit in the C register. If the argument requires two words, these words will be located in the A register and B register and the exit will be located in the C register. Subroutine exits will normally be complete instructions (unconditional transfers).

3.5 FLOW DIAGRAMMING CONVENTIONS

Flow diagrams are divided into two groups as follows:

a) Macro Flow Diagrams -- broad, descriptive flow diagrams, outlining a large, complex program. They are not oriented to the program logic but serve to provide a general picture of how the program operates, and also serve as a guide to a more detailed flow diagram.

b) Micro Flow Diagrams - - machine oriented diagrams whose functions is to define the program logic.

Table 3-1 lists the standard flow diagram symbols used in PB 250 programming. These symbols have been selected both for their convenience and universal acceptance. With the exception of the start symbol, they represent the flow chart symbols recommended for use by the Association for Computing Machinery.
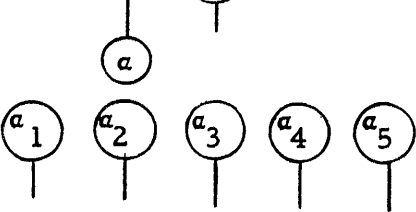

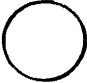

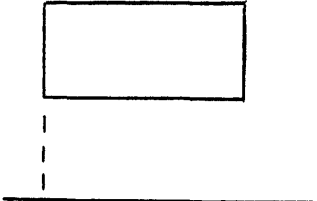

Referring to the table, small English letters are used to identify fixed connectors while small Greek letters with numerical subscripts are used to identify variable connectors. To avoid possible confusion, it is recommended that the flow diagram page number be included with the connector to facilitate following the flow diagram.

To aid personnel unfamiliar with a particular program, important and significant micro flow diagram boxes are cross-referenced to the program listing by having the location (line and sector) of the first instruction executed within the respective box (in the upper right hand corner as shown below). It is emphasized that not all boxes of the flow diagram are keyed to the listing. Cross-referencing of all boxes on the flow diagram requires the performance of considerable updating by the programmer responsible for maintaining the program. In many cases, because of the auxiliary nature of this cross-referencing, the diagrams may not be kept up to date; therefore, the number of cross-reference boxes should be kept to a minimum.

SSSLL

Table 3-1

STANDARD FLOW DIAGRAM SYMBOLS

SYMBOL	MEANING
	Tape (Magnetic)
	Operation, Function
a	Fixed Connector
a_1 a_2 a_3 a_4 a_5	Variable Connector
	Comparison, Test, Decision
	Closed Subroutine
	Start, Stop
	Assertion, Explanation
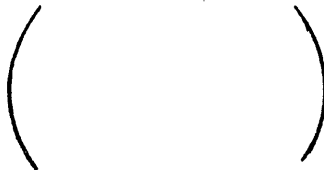

Care must be taken to make the flow diagram appear clear and un-cluttered. This can be avoided by minimizing the number of boxes per page.

The wording appearing in the flow diagram box should be as descriptive as possible. Language contained in the micro flow diagram is more general than that contained in the listing annotations.

3.6 ANNOTATION CONVENTIONS

The following annotation symbols and conventions will be used:

a) ——————— Replaces: e.g., $(A) + (X)_i$ —— (A), contents of A plus contents of X_i replace contents of A.

b) $\Big($ $\Big)$ Contents of: e.g., (A), contents of A register; $(X_i$ contents of location X_1; (10002), contents of sector 100, line 02.

c) $\Big[$ $\Big]$ Modified Command: a command which is modified by another command within the same subroutine. Commands within a particular routine will never be modified by commands, outside that routine.

d) Brackets are used to identify all instructions included in a particular annotation, as follows:
e) The word "enter" is inserted to the left of the first instruction operated in a particular routine. The exit or exits from a routine should be clearly annotated.

f) Annotations should include the listing page number of all transfers whose locations are not included on the same page.

g) The binary point of a number is identified using Q notation, i.e., to represent an integer, N, on an annotated listing, the programmer would write: N @ 21.

3.7 AVAILABLE PB 250 PROGRAMS

Table 3-2 lists some of the standard routines which are available for the PB 250.

IV. INPUT-OUTPUT TECHNIQUES

4.1   FLEXOWRITER

A Model FL Flexowriter is used as the input-output control unit for the PB 250. The Flexowriter is also used to prepare, duplicate, and read tapes and can be used on-line (under control of computer), or off-line (under control of operation). This section is primarily concerned with the on-line mode of operation. General appearance and operations are similar to those of a standard electric typewriter. Such features as space lever, paper release lever, platen knobs, margin release lever, ribbon position lever, margin and tab stops, and type guide, are used in exactly the same manner as for a standard typewriter. See Figures 4-1, 4-2, and 4-3 for illustrations of the Flexowriter keyboard, code, and characters, respectively.

4.1.1   Input

The tape used with the Flexowriter has eight channels across its width. The keys of the typewriter, however, will only cause 6-bit codes to be punched on this tape. When punching tape under computer control, it is possible to output 8 bit of information at a time. It is desirable to utilize all eight channels on the tape wherever possible, since this reduces the number of frames of tape that must be input or output for a block of information.

When the READ TYPEWRITER KEYBOARD (RTK) command is given, the light on the front of the Flexowriter will come on and it will be possible to enter information, in the form of 6-bit codes, into the Input Buffer. Each time a key on the typewriter is depressed, the light will go off and it will be necessary to give another RTK command before another code can be entered.
Figure 4-1.   Flexowriter Keyboard

Figure 4-2.   Flexowriter Code

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z 1 2 3 4 5 6 7 8 9 0 + - ' ; $. ,

Figure 4-3.   Flexowriter Characters

The READ PAPER TAPE command will cause the tape reader to read one frame of tape and then advance the tape one frame. Eight bits of information will be loaded into the buffer. If the tape was prepared in the PB 250 Flexowriter format, only six of these eight bits will be significant; however, if the tape was prepared by the computer, all eight bits may have significance.

When either the tape reader or the keyboard has loaded the buffer, a signal is sent to the computer, which may be sensed by a TES command having a line address of $36)_8$. This signal deactivates the Input Buffer so that it cannot be loaded with further information. Any time after either an RTK or RPT command is given, the presence of information in the buffer may be sensed by giving a TES command with a line number of $36)_8$. If the buffer has been filled, the transfer will occur.

Since the maximum speed of the Flexowriter for both the reader and the keyboard is 10 characters/second, and the PB 250 operates at microsecond speeds, it is possible for a program to be ready for another input before the Flexowriter has finished with the previous input; if a READ command were given during this time period, the same character would be read again.

To keep the Flexowriter tape reader operating at its maximum rate, and at the same time avoid reading the same character twice, a sequence of commands can be used with either the RPT or RTK commands to provide an automatic method of determining if character read-in is complete. This method proceeds by giving a READ command and then testing line $36)_8$ after only 3 ms. If line $36)_8$ is true, it can be assumed that a previous character is being read, since the Flexowriter cannot react in 3 ms. The sequence then cycles through these two commands, READ and TES $36)_8$, until the TES fails, which will occur only when the previous read-in is complete. Then, by clearing the buffer and waiting for line 36 to go true, the next READ will fill the Input Buffer with a new character.

The command sequence is illustrated in the following flow diagram (nth character to be read):
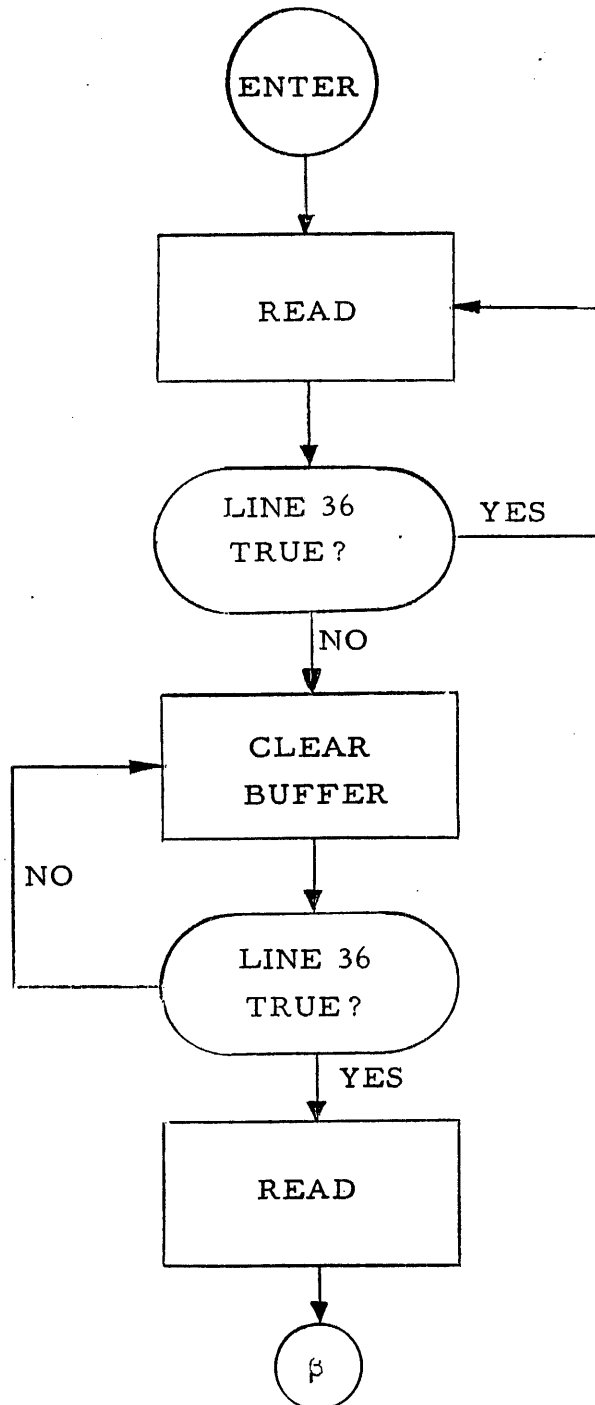

if line 36 is true, previous character is being read.

ine 36 is typewriter or paper tape reader character input complete" signal. Apparently goes false for a fixed time interval (.03 sec?) when input is completed, then true again.

```
                    ( ENTER )
                         |
                         v
        +------------------------------+
        |            READ              |<----+
        +------------------------------+     |
                         |                   |
                         v                   |
                  (  LINE 36   )    YES       |
                  (  TRUE ?    )------------->+
                         |
                        NO
                         v
        +------------------------------+
        |          CLEAR               |
        |          BUFFER              |<----+
        +------------------------------+     |
                         |                   NO
                         v                   |
                  (  LINE 36   )             |
                  (  TRUE ?    )-------------+
                         |
                        YES
                         v
        +------------------------------+
        |            READ              |
        +------------------------------+
                         |
                         v
                      ( β )
```

4-4

The command sequence for the read operation is as follows:

Location Sector	op Code	Line Address	Sector Address	Seq Tag
β	LAI (etc)			
.	.	.	.	
.	,	.	.	
α	TRU	LL	α + 2	S
α + 1	READ	00	β - 1	S
α + 2	READ	00	α + 3	
α + 3	TES	36	α + 2	
α + 4	TES	36	α + 1	
α + 5	CIB	00	α + 3	S

The function of the sequence is as follows:

The sequence is entered at α + 2, where a READ command with sector α + 3 and no sequence tag is executed. After 3 ms, line 36 is tested and if the line is "true", control returns to the READ command. If line 36 is not "true", control will pass through to the CIB command which clears the buffer and returns control to the second TES 36. The program will wait in this TES-CIB loop until line 36 goes "true", at which time the TES 36 will transfer to the READ in α + 1. This READ will execute for the greater part of a memory circulation and then transfer control to β , the next operation. Although β is not a fixed location it should be as far from α + 1 as possible, that is α or α - 1.

4.1.2   Output

There are two ways to obtain output on the Flexowriter: the typewriter, which has a speed of 10 characters/second, and the punch, which operates up to 15 characters/second.

To type out on the typewriter, the WOC command must be located in line 05. In order to give the Flexowriter time to respond to the output signal, it is necessary to load the C register with a delay number before executing the WOC command. This number will be decremented by one for each sector of execution until it goes negative, at which time the WOC acts like a standard class 1 command. For the typewriter, a signal of 20 milliseconds duration is always sufficient; however, for some Flexowriters, less time may suffice. To obtain this delay, an octal number, + 0003232, should be loaded into the C register before execution.

In order to avoid sending an output signal before the typewriter has completed a previous character, a TES command with a line number of $37)_8$ should be used to test for "typewriter busy." Line 37 will become "true" 11-13 milliseconds after the WOC command has started, and will remain true for as long the typewriter is busy typing a character. The TES 37 command may be used to transfer back on itself, and in this way produce a one-word loop until the typewriter is ready to receive the output character.

Information output on punched paper tape is faster than output using the type-writer and is controlled in almost the same way as the typewriter, except that the WOC command is located in line 06 instead of 05. In the case of the punch, a 15-millisecond delay is always long enough to start the punching operation, instead of the 20-millisecond delay required for the typewriter. There is, however, no way to test for the punch being busy and the programmer must always allow sufficient time between characters. One method of testing is to calculate the amount of time used by the program in its operations between characters, and then to make up the remainder of the time by using a larger delay number for the WOC command. It is permissible to use a WOC for longer than 15 milli-seconds, but no longer than approximately 60 milliseconds. In this way, it is possible to output a tape without the necessity of using an additional counter.

For the 15-millisecond delay, an octal number of + 0002424 should be loaded into the C register.

V. COMPUTER OPERATION AND PROGRAM CHECKOUT

5.1   COMPUTER OPERATION

The POWER button on the front panel of the computer is the only control necessary to turn the machine ON or OFF. When the computer is on, this button will be illuminated. The Flexowriter ON-OFF switch is located on the Flexowriter.

When loading a program, the Octal Utility Program, which is presented in Appendix C, should be used. This utility package simplifies control of the PB 250 during program operation and checkout.

The delay line memory of the PB 250 is erased when power is removed and, upon turning the machine on again, the contents of memory will not necessarily be all zeroes, but will be a random bit configuration. In consequence, parity halts may be generated by trying to load the A, B, or C registers with sectors in which information has not been previously stored.

5.2   PROGRAM CHECKOUT

5.2.1   Dumping and Tracing

Once a program has been coded, punched and loaded into the computer, the question still remains as to whether the program, as written, is correct. In the event that the program produces a print-out of results, these results can be compared with known results obtained by hand computation of test cases. In the event the program does not perform as predicted, several courses are open to the operator. A static dump (memory print-out) of the contents of appropriate memory locations may be made, or the program may be traced, which is a dynamic process showing the conditions of the various registers as computation proceeds.

5.2.2   Single-Step Operation

An easier approach than either dumping or tracing, is to single-step the computer through the program and, by comparing the results shown on the console lights with annotated coding sheets, find the flaw or flaws in the program. Single-stepping may be accomplished by depressing the ENABLE switch and depressing the C Key on the Flexowriter once for each program step to be executed. Note: Each time any Flexowriter key is depressed, the Input Buffer is loaded with this character. In addition, certain commands appear in the OPERATION lights as other than that which is actually being executed; these commands are as follows:

> ROT (03), which shows as 01
>
> LDP (07), which shows as 05
>
> STD (13), which shows as 11
>

>
> DPS (17), which shows as 15

For class 1 commands, such as MUP, DIV, etc., the information displayed in the OPERAND lights will not reflect the actual line number of the command being executed.

Conditional transfer commands will not appear in the OPERATION lights unless the condition necessary for transfer is present. For example, TBN (36) will always be executed (i. e., either a transfer will take place if B is negative, or the regular instruction sequence will continue if B is not negative) but will not appear in the OPERATION lights unless the B register is negative when this command is being executed.

Within the limitations previously described, the console indicator lights may be interpreted as follows:

OPERATION lights (6) ------- Op code of command

OPERAND lights   (5) ------- Line address of command

COMMAND lights   (3) ------- Line location of command

Note that single-stepping through class 1 commands located in line 00 will in general give incorrect results.

5.2.3   Use of The FILL Switch

During checkout, it may be necessary to reload the Octal Utility Package using the FILL switch. Programs other than the Octal Utility Package will be destroyed when the FILL switch is turned on if the extreme left-hand light of the OPERATION lights is illuminated. To turn this light off, single-step the computer from the Flexowriter until the light goes out. The bootstrap leader on the Octal Utility Package may then be loaded by the FILL switch without disarranging the rest of memory.

5.3   BOOTSTRAP LOADING

5.3.1   Method

When the computer is first turned on, it is necessary to load a small service routine, called a bootstrap, into the computer by turning on the FILL switch, which is located on the computer console. This bootstrap program, in turn, is used to load the Octal Utility Package which is capable of loading tapes in conventional 6-channel or 8-channel format. The bootstrap tape is a special binary information tape with the information arranged as shown in the following diagram.

Sprocket Holes

Information Channel

Stop Channel

Direction of Tape Motion →
Bootstrap tapes load one information bit at a time, starting with the guard bit of sector 377 of line 01. The next bit enters the guard bit of 377 and pushes the bit previously loaded, down to position 21 of 377. This continues through the parity bit of 377 and into the guard bit of 000 of line 01, as follows:

00101   00001   37701

| G | P | — — — — | G | P | O | — — — — — | 21 | G | P | O | — — — — — | 21 | G | ← — 7

← Information Flow

Information Entry
Codes on the bootstrap tape are as follows:

(Zero)	0	0
	H	1
	C/R	Guard Bit
	Stop Code	Stop Loading (After last C/R) Always preceded by a zero

5-4

For each word that is loaded, a parity bit must have been computed and punched. A stop code on the tape will cause the tape read in to cease, at which time the operator may transfer to 00001 by first turning off the FILL switch then depressing both the ENABLE and BREAKPOINT switches, striking the I key and raising the ENABLE switch.

BINARY-OCTAL NUMBERS

A. NUMERICAL SYSTEMS

Any number can be represented as the sum of a group of terms, having the form $a_n b^n \ldots + a_3 b^3 + a_2 b^2 + a_1 b^1 + a_0 b^0$, where $b > 1$ and $0 \leq a \leq (b-1)$. The integer "b" is called the base, or radix, of the particular numerical system, while "a" represents the range of numerical values in that system.

1. Decimal System

The numerical system of radix 10 is called the decimal system. In this case, numerical values are specified by combining powers of ten in the form $a_n (10^n) \ldots + a_3 (10^3) + a_2 (10^2) + a_1 (10^1) + a_0 (10^0)$. The usual practice, when writing decimal numbers, is to omit the powers of ten and write out only the values of "a". For example, consider the decimal number 1875. This number actually represents $1 (10^3) + 8 (10^2) + 7 (10^1) + 5 (10^0)$ but for the sake of convenience is merely written as 1875, with the position of the particular decimal digit indicating with which power of ten the digit is associated.

2. Binary System

The PB 250 operates in the binary, or radix 2, mode; therefore, to understand the operation of the computer, an understanding of binary arithmetic is essential.

Here, numerical values are specified by combining powers of 2 in the form $a_n (2^n) \ldots + a_3 (2^3) + a_2 (2^2) + a_1 (2^1) + a_0 (2^0)$. As before, the usual practice when writing binary numbers is to omit the powers of 2 and write out only the values of the "a" terms. For example, consider the binary number 1011. This number actually represents $1 (2^3) + 0 (2^2) + 1 (2^1) + 1 (2^0)$ but for the sake of convenience is merely written as 1011, with the position of the particular binary

digit (or bit) indicating with which power of 2 the digit is associated. The only digits available in binary notation are 0 and 1.

3. Octal System

In the octal system, numbers are specified by combining powers of 8 in form $a_n(8^n) \ldots + A_3(8^3) + a_2(8^2) + a_1(8^1) + a_0(8^0)$. For the decimal and binary systems, the powers of the base (8 in this case) are omitted, and only the values of the "a" terms are written. For example, the octal number 7142 actually represents $7(8^3) + 1(8^2) + 4(8^1) + 2(8^0)$. The digits available in octal notation are 0, 1, 2, 3, 4, 5, 6, and 7.

B. RADIX CONVERSION

It is frequently necessary to convert numbers from one base, or radix, to another during programming operations. The more common conversions are described in this section.

1. Decimal-to-Binary Integer Conversion

Assume it is desired to convert $25)_{10}$ to binary form. Note: The notation $)_{10}$ indicates radix 10, or decimal system; $)_8$ indicates radix 8, or octal system; $)_2$ indicates radix 2, or binary system.

a) From the definition of the general binary form, it can be seen that the decimal integer can be broken down into a summation of successive powers of 2.

$$25)_{10} = 1(2^4) + 1(2^3) + 0(2^2) + 0(2^1) + 1(2^0)$$

For larger decimal integers, make use of the Table of Powers of 2, in Appendix B. Note: Adding the above terms would yield $16 + 8 + 0 + 0 + 1 = 25$.

b)   The decimal integer can be divided repeatedly by 2; the successive remainders, when read from the end, will be the desired value.

Remainders

$$
\begin{array}{ll}
2\,\lfloor\,25 & \quad 1 \longleftarrow \text{ least significant bit } (a_0) \\
\quad 2\,\lfloor\,12 & \quad 0 \\
\qquad 2\,\lfloor\,6 & \quad 0 \\
\qquad\quad 2\,\lfloor\,3 & \quad 1 \\
\qquad\qquad 2\,\lfloor\,1 & \quad 1 \longleftarrow \text{ most significant bit } (a_4) \\
\qquad\qquad\quad 0 &
\end{array}
$$

As before, $25)_{10} = 11001)_2$

This method follows from the fact that when converting an integer, N, to the form $N = a_n 2^n + \ldots a_1 2^1 + a_0 2^0$, the remainder, when N is divided by 2, is a_0; dividing this first quotient by 2 yields a_1 as a remainder, etc.

2.   Binary-to-Decimal Integer Conversion

Assume it is desired to convert $11110)_2$ to decimal form:

a)   The values of the powers of 2 can be summed up to give the decimal equivalent.

$11110)_2 = 1(2^4) + 1(2^3) + 1(2^2) + 1(2^1) + 0(2^0)$

$= 16 + 8 + 4 + 2 + 0 = 30)_{10}$

Therefore, $11110)_2 = 30)_{10}$

b)   A second method is to multiply the most significant bit by 2, add the next most significant bit, multiply the resulting sum by 2, add the next most significant bit, etc.

$$1 \quad 1 \quad 1 \quad 1 \quad 0)_2$$

$\dfrac{2}{2}$ multiply

$\dfrac{1}{3}$ add

$\dfrac{2}{6}$ multiply

$\dfrac{1}{7}$ add

$\dfrac{2}{14}$ multiply

$\dfrac{1}{15}$ add

$\dfrac{2}{30}$ multiply

$\dfrac{0}{30)_{10}}$ add   ←—— answer
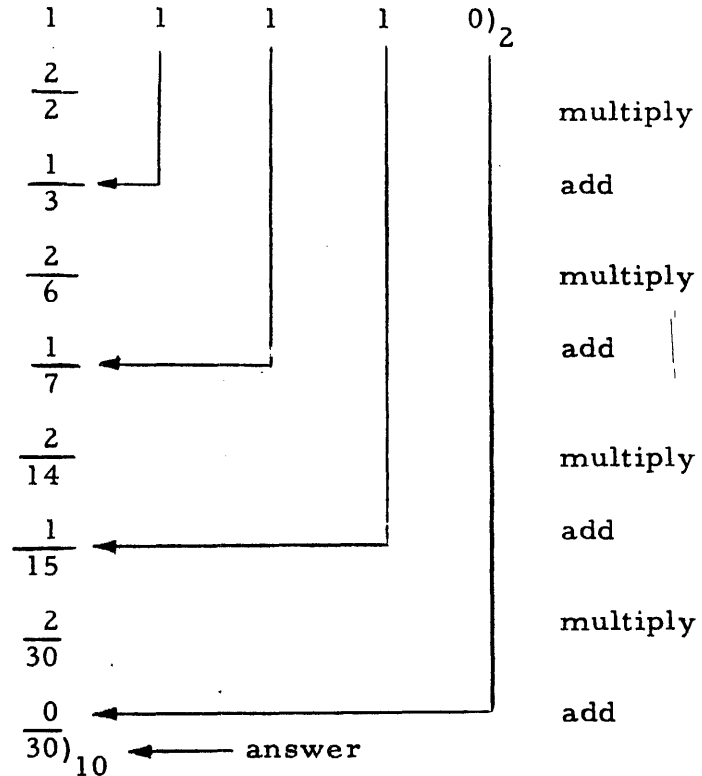

As before, $11110)_2 = 30)_{10}$

This method follows from factoring the general binary term for a 5-bit number to obtain the form

$$N = a_0 + 2(a_1 + 2(a_2 + 2(a_3 + 2(a_4)))) $$

Evaluating N, starting at the inner parentheses, gives the required decimal integer.

3. Decimal-to-Octal Integer Conversion

To convert a decimal integer to octal form, divide the number repeatedly by 8; the successive remainders, when read from the end, will be the desired octal value.

For example, convert $75)_{10}$ to octal.

```
8  75        3 ◄————— least significant digit
   8 |9      1
      8 |1   1 ◄————— most significant digit
         8 |0
```

Therefore, $75)_{10} = 11\ 3)_8$

This method follows from the fact that when an integer, N, is converted to the form $N = a_n 8^n + \ldots a_1 8^1 + a_0 8^0$, the remainder, when N is divided by 8, is a_0; dividing this first quotient by 8 yields a_1 as a remainder, etc.

Note: It is usually convenient for the programmer to refer to the Octal-Decimal Integer Conversion Table, Appendix B, when converting integers from decimal to octal and vice-versa. The use of this table is self-evident.

4. <u>Octal-to-Decimal Integer Conversion</u>

To convert an octal integer to decimal form, multiply the most significant digit of the number by 8, add the next most significant digit, multiply the resulting sum by 8, add the next most significant digit, etc. For example, convert $155)_8$ to decimal.

```
  1      5      5)8
  8      |      |
  ─      |      |        multiply
  8      |      |
  5 ◄────┘      |        add
 ──            |
 13            |
  8            |        multiply
 ───           |
 104           |
  5 ◄──────────┘        add
 ────
 109)10 ◄── Answer
```

Therefore, $155)_8 = 109)_{10}$

This method follows from factoring the general octal term (for a 3-digit number) to obtain

$$N = a_0 + + 8 (a_1 + 8 (a_2))$$

Evaluating N, starting at the inner parentheses gives the required decimal integer.

5. Binary and Octal Number Relationships

Since $2^3 = 8$, it can be seen that three binary digits are represented by one octal digit. This applies for fractional quantities as well as for integers.

The binary-to-octal conversion is performed by grouping the binary number into 3-bit units, starting from the binary point, and interpreting each unit individually. For instance, $101011010)_2$

becomes $\underbrace{1\ 0\ 1}_{5}$ $\underbrace{0\ 1\ 1}_{3}$ $\underbrace{0\ 1\ 0}_{2}$

or $532)_8$

and $0.110111)_2$

becomes $\underbrace{.110}_{6}$ $\underbrace{111}_{7}$

or $.67)_8$

Conversely, it can be seen that any octal number can be converted to binary by writing the binary equivalent of each octal digit. For example, $612)_8$

becomes $\underbrace{6}_{1\ 1\ 0}$ $\underbrace{1}_{0\ 0\ 1}$ $\underbrace{2}_{0\ 1\ 0}$

or $110001010)_2$

A-6

6. Decimal Fractions to Octal or Binary

Keeping in mind that the general term for a fraction, base b, is

$$a_{-1} b^{-1} + a_{-2} b^{-2} + a_{-3} b^{-3} + \text{----}$$

it is evident that multiplying by the base, b, will produce the a_{-1} term in the units position (immediately to the left of the radix point). Successive multiplication by the base will successively isolate the a_{-2} term, a_{-3} term, etc.

By this process, a decimal fraction, D, can be converted to the octal form $D = a_{-1} 8^{-1} + a_{-2} 8^{-2} + a_{-3} 8^{-3} + \text{----}$, or to the binary form

$$D = a_{-1} 2^{-1} + a_{-2} 2^{-2} + a_{-3} 2^{-3} + \text{----}$$

Note: A fraction in one base will not usually transform to a finite fraction in another base.

For example, to transform $0.725)_{10}$ into a binary fraction, multiply the fraction successively by 2, isolating the units position after each multiplication, until the desired number of bits are generated.

$$.725$$
$$\underline{\qquad 2}$$
a_{-1} term $\longrightarrow$ $\underline{1}.450$

$$\underline{\qquad 2}$$
$$\underline{0}.900$$

$$\underline{\qquad 2}$$
$$\underline{1}.800$$

$$\underline{\qquad 2}$$
$$\underline{1}.600$$

Therefore $.725)_{10} = .1011 \text{---})_2$

To convert $.082)_{10}$ to octal, multiply the fraction successively by 8, isolating the units position after each multiplication, until the desired number of octal digits are generated.

$$.082$$
$$\underline{\quad 8 \quad}$$

a_{-1} term $\longrightarrow$ 0. 656
$$\underline{\quad 8 \quad}$$
$$5. 248$$
$$\underline{\quad 8 \quad}$$
$$1. 984$$

Therefore $.082)_{10} = .0517\overset{67}{---})_8$

The Octal-Decimal Fraction Conversion Table, Appendix B, is useful for decimal-to-octal or octal-to-decimal fractional conversions.

7. Binary or Octal Fractions to Decimal

Remembering the general notation for a fraction, it is evident that a binary fraction can be converted to decimal by adding up the negative powers of 2, referring to the Table of Powers of 2, Appendix B.

For example, convert $.101)_2$ to decimal

This fraction equals $1 (2^{-1}) + 0 (2^{-2}) + 1 (2^{-3})$

Therefore, $.101)_2 = .625)_{10}$

It is also possible to convert the binary fraction to octal and look up the corresponding decimal value in the Octal-Decimal Fraction Conversion Table.

In the above example, $.101)_2 = .5)_8$

From the table, $.05)_8 = .078125)_{10}$

Multiplying both sides by 8: $.5)_8 = .078125 \times 8)_{10} = .625)_{10}$

C. BINARY COMPLEMENTARY ARITHMETIC

Certain computer operations, such as subtraction or the manipulation

of negative numbers, are performed in the computer by using the complement of the particular number. An understanding of complementary arithmetic is therefore important as an aid in understanding computer operation.

The 1's complement of a binary number is defined as the number that must be added to the original number to give a result consisting of all 1's. The 1's complement is obtained by simply inverting, i.e., by changing all 1's to 0's and changing all 0's to 1's in the given binary number. For example, the 1's complement of 1010110 would 0101001.

The 2's (or "true") complement of a binary number is formed by first finding the 1's complement of the number and then adding 1 to the least significant bit position.

For example, the 2's complement of 1010110 would be the 1's complement (0101001) plus 1, or 0101010.

Some examples are given on the following page in decimal, binary and complemented binary forms. The complemented binary form has a leading 0 to indicate positive numbers, which becomes a leading 1 when complemented for negative numbers. A negative answer appears in complemented form with a leading 1.

Note that in 2's complement a number plus its negative gives zero. This is not true in 1's complement.

	Decimal	Binary		2's Complemented Binary
a)	+12	+1100		0 1100
	-04	-0100		1 1100

APPENDIX C

OCTAL UTILITY PROGRAM

IDENTIFICATION: OCTAL UTILITY PACKAGE II

AUTHOR: A. W. England, PBCC

ACCEPTED: February 27, 1961

PURPOSE: To provide simplified control of the PB250 during pro-
                    gram operation and checkout.   The utility program
                    operations are easily controlled by means of appropriate
                    code letters, which allow the user to enter, inspect, and
                    output information in a variety of formats.

RESTRICTIONS: Only those codes which are recognizable by the program
                    should be entered; these include 0 to 9, +, -, semicolon
                    (;), comma (,), period (.), $, Tab, C/R, Delete, Space,
                    B, C, D, F, G, I, S, T, W, Z.   Entry may either be
                    from paper tape or from the Flexowriter keyboard.

                    Of the remaining codes, any which have an octal configu-
                    ration of 40 or greater will cause erratic and unpredictable
                    operation.   In this group are A, E, H, U, V, X, Y, apos-
                    trophe ('), U/C, L/C.   Any codes which have an octal con-
                    figuration less than 40 will be interpreted as octal digits,
                    the value being determined by the least significant three
                    bits of the code; included are J, K, L, M, N, O, P, Q, R,
                    /, Stop Code, Tape Feed.

SPACE: The program uses all sectors of line 01 for instructions
                    and storage, plus additional memory as follows: (1) When
                    punching, sectors 376 and 377 of line 06; (2) When typing,
                    sectors 376 and 377 of line 05.

TIMING: Since this is essentially an input-output program, its speed
                    is determined by the speed of the Flexowriter. All opera-
                    tions will proceed at the maximum rate for the Flexowriter,
                    which is about 10 characters/second for reading tape and
                    typing, and 15 characters/second for punching.

USE:

1. Loading the Program

The utility program has a bootstrap and is self-loading.
To load the program, insert the tape into the reader. The
starting point is not critical, but it must be before the
first set of holes. Raise the Fill switch on the console
and clear any parity by depressing both the Enable and
Breakpoint switches. Be sure to raise one of these after
the tape starts moving.

The tape will stop when the bootstrap has been entered. To
read the remainder of the utility tape, first lower the Fill
switch, then clear parity and initialize by depressing both
the Enable and Breakpoint switches and striking the I key
while the Enable switch is down. When the Enable switch
is raised, the tape will be read under program control (The
Breakpoint switch may be up or down).

When the tape has been read in correctly (the check sum
compares), the light on the Flexowriter will come on, in-
dicating keyboard control. If the Flexowriter light does
not come on, and $0037)_8$ appears in the Operation and Oper-
and lights of the console, the check sum did not compare
and the program should be loaded again.

The functions of the utility package will normally be con-
trolled from the Flexowriter keyboard. The keys for the
input, output, control, and function operations are described
in the following paragraphs.

2. Input Codes

a) $ (Set Location)

Causes the specified location to be set for the input of
information. The user first types five octal digits of
the form SSSLL, where SSS is the sector and LL the
line number of the location to be set, and then $. SSS
may be any octal number from 000 to 377, and LL any
octal number from 00 to 37. Regardless of the number
of digits entered prior to the $, only the last five will

USE (cont.):

be interpreted as an address. The sector number will be inserted into an indexed store command, and the line number will be stored in the index register.

b)   Carriage Return (Enter)

Used to enter a word of information into a location previously set with $. After one word is entered, the location counter is advanced by one, with sector 000 following 377, so that the next C/R will enter a word into the next location. Each time the C/R is given, the contents of the program accumulator are entered into the location specified by the sector counter; the contents of the accumulated word are not affected. Regardless of the number of characters preceding the C/R, only the last 21 bits will be entered into the specified location.

c)   F   (Fill)

Causes the program to begin reading paper tape. This tape may be prepared ahead of time in the same format used when entering from the keyboard, in which case the control codes are interpreted as if they were typed. A location of the form SSSLL may be specified before the F code, and this will be set the same as with $. However, any $ on the tape will override the setting of the F.

The tape may also have been prepared by the utility program in a binary format in blocks of 256 words (one long line, see discussion of Output Codes) plus check sum. In this case, it is only necessary to set a line location either by typing LLF or by having placed LL$ or LLF on the tape before the binary block was punched.

At the beginning of the binary block will be a G, placed there at the time of punching by the program, which marks the start of the block. After loading the line specified, the check sum on the tape is compared with the

USE (cont.):

sum computed during loading. If the check sum was correct, the program will continue to read in the normal F mode unless the Breakpoint switch is down, in which case control will return to the keyboard.

If the check sums do not compare, the program will halt with a line number of $37)_8$ appearing on the console. Control may be returned to the keyboard by depressing both the Enable and the Breakpoint switches together; when the Enable switch is raised, the Flexowriter light will come on. The computed check sum will be stored in F17 of line 00. It may be typed out in octal by typing "01700D."

A "W" will also cause control to return to the keyboard, regardless of the position of the Breakpoint switch.

d)   G   (Guard)

This code guards the beginning of a binary block and is always punched by the program when preparing a binary tape. It should never be necessary for the user to depress this key.

3.   Output Codes

a)   B   (Binary)

A line number ranging from 00 to $37)_8$, followed by a B, will cause the indicated line to be punched in a binary format starting from sector $177)_8$ and proceeding backward to sector $200)_8$. In this format, three frames on tape are required for each word in memory. The first has six bits of information, whereas the next two each contain eight bits. At the end of the tape, a check sum will be punched. This check sum is compared when the tape is reentered into the computer. Twice this check sum will be stored in line 00, channel F17.

A G code will be punched to mark the beginning of the tape.

USE (cont.):

b)   C   (Command Type)

To type out a word in command format, first type the location of the word (SSSLL) followed by a C; the program will then type this word, carriage return, and if the Breakpoint switch is up, type the next word.   Typing will continue until the Breakpoint switch is depressed.   If the Breakpoint switch is down when C is depressed, only one word will be typed.

c)   D   (Data Type)

To type out a word in octal format, follow the same procedure as in C, except depress the D key instead of the C key.

d)   Output Note

It is not possible to punch a listable tape directly, however, if the punch is turned on while the program is typing out in command or octal format, a tape will be punched which can be read into the computer.

4.   Transfer-Control Codes

a)   .   (Period)

The period will cause control to be transferred to the location specified by the preceding five octal digits (SSSLL).   Control can be transferred to any sector of lines 00 thru 07.

b)   W

When read from tape by the program, W will cause control to be returned to the keyboard.   It is useful at the end of listable, octal format tapes, to return control to the keyboard.   It is also useful at the end of binary tapes, if control is to be returned to the keyboard regardless of the position of the Breakpoint switch.

USE (cont.):

c)   T

This code causes an unconditional transfer to sector 000 of line 02. The transfer command is located in sector 306 of line 01 and can be changed for use by a specific program. Any program which changes 306 01 should also make provision for restoring the original contents of this location upon completion of the program.

d)   ,   (Comma)

Whenever a \$, F, B, C, D, or . code is read, the utility program stores the two octal digits preceding the code in the Index register. The comma (,) code makes use of this fact and transfers control to sector 000 of the line specified in the Index register; it can be used for a self-starting program tape that may go into any of several lines.

e)   Enable - I

Control may always be returned to the keyboard from any place at any time by depressing the Enable switch and striking the I key. When the Enable switch is raised, the Flexowriter light will come on unless there is a parity which must also be cleared.

5.   Function Codes

a)   Z   (Zero One Line)

This code will cause the contents of the indexed line to be set to zero. It is first necessary to set the desired line number into the Index register with an LL\$, or equivalent, and then to zero the accumulated word by typing +0000000. Then, when the Z code is read, the desired line will be cleared and control will return to reading from whichever mode (tape or keyboard)the code was given. The accumulated word is not stored in the sectors of the line, but it must be cleared before the operation functions properly. The time required for this operation is less than 2 seconds.

USE (cont.):

6. **Input-Output Formats**

a) Command Format

A command format word has three octal digits for sector number, one bit for sequence tag, two octal digits for operation code, two octal digits for line number, and a one-bit index tag.

For example: In command 123S45071, 123 is the sector number, S indicates that there is a sequence tag, 45 is the operation code, 07 the line number, and I indicates that there is an index tag. If there were no sequence tag, a space should be typed instead of the S; likewise, if there were no index tag, semicolon (;) should be typed instead of the I. Output will be in the same form as input.

The line number consists of six bits (two octal digits), but these are arranged with the most significant bit on the <u>right</u> of the six, next to the index tag. It is not necessary for the user to concern himself with this, however, as the program will automatically arrange this bit on input and rearrange it for output.

b) Data or Octal Format

An octal format word has a sign and seven octal digits. For example, +1234567 or -3214276. Negative numbers are not complemented either on input or output. The minus sign causes a one bit to be entered for the sign position; plus produces a zero in the sign position.

c) Tab and Code Delete

For convenience, the tab is ignored when entered from either tape or keyboard. The code delete is also ignored when read from tape.

METHOD:

1. When reading information in octal format from either tape or keyboard, the program inspects each character for the presence of a bit in the most significant position. If a one is present, it interprets this as a control code and jumps to the appropriate routine. If the high-order bit is a zero, the program assumes the character to be an octal digit and loads the three low-order bits of the character into the low-order positions of an accumulating word which is shifted left to allow insertion of the digit.

2. The four one-bit characters, S, Space, I, semicolon (;), cause insertion of only one bit into the accumulator. In addition to inserting one bit, I and ;, also cause the preceding six bits to be rearranged by moving the most significant bit of the six to the least significant position.

3. The control characters which require an address assume that this address is the last thing entered into the program accumulator. The Index register is then set with the line number of the address, and the sector number is placed into an appropriate load or store command. None of these control characters rearrange the line number, therefore, it is impossible to set a line number greater than $37)_8$.

APPENDIX A

OPERATIONS SUMMARY

OCTAL UTILITY PACKAGE II

Set location counter	SSSLL$
Enter accumulated word and advance location counter	C/R
Set location counter and fill from tape	SSSLLF
Punch line in binary format	LLB
Type word in command format	SSSLLC
Type word in data (octal) format	SSSLLD
Jump to specified location	SSSLL.
Return control from tape to keyboard	W
Jump to sector 000 of line 02	T
Jump to sector 000 of last line indexed	,
Clear indexed line to +0000000	LL$+0000000 Z
Sequence tag: one (1)	S
Sequence tag: zero (0)	Space
Index tag: one (1)	I
Index tag: zero (0)	;
Sign plus: + (0)	+
Sign minus, - (1)	-
Ignored codes:	{ Tab Code delete

APPENDIX D

OCTAL UTILITY PACKAGE II
BOOTSTRAP

The bootstrap section of this program is actually the binary loading portion of the complete program. After the bootstrap is loaded by means of the binary fill mode (controlled by the Fill switch on the console), the bootstrap pulls in the rest of the program around it, without using more than one additional sector in another line. The bootstrap routine itself occupies 25 sectors from $377)_8$ - $027)_8$; of this, sectors 001 - $027)_8$ are actually part of the completely loaded program.

In the bootstrap only, the binary loading routine starts loading into sector 000 and loads the main program backwards through sector $030)_8$. This method produces the shortest possible tape and the fastest loading time. Ordinarily, loading starts with sector 177.
