Assembled Listings

INTRODUCTION

The most effective method of translation from problem statement to program statement on the AN/UYK-1 (TRW-130) is by use of the interpretive mode of operation. The interpretive mode is the term used to describe the operational mode of the computer while executing instructions defined by a logram set. A primary advantage of this technique is that it provides the user with a logram set most useful to his purposes. He may augment or delete lograms from this set as required, and may develop special purpose lograms as the need arises. It is useful, however, to develop a common set of lograms which will fulfill the requirements of a wide variety of applications. Such a set is the "Basic Logram Set - TRW-130," described herein.

This Basic Logram Set is a part of the AN/UYK-1 (TRW-130) Logram Library. The Logram Library includes many more lograms and is constantly expanding as the TRW-130 is used in different applications. The Basic Logram Set merely represents those lograms that almost everyone using a TRW-130 will require.

The TRW-130 users will have a Software Library Catalog from which they may select lograms and other software useful to their applications.

As with all lograms, the Basic Logram Set has a consistent structure to allow simple, reliable extension and revision and to permit programmed diagnostic techniques. These programming standards and conventions along with detailed descriptions and program listings of each logram are presented in sections to follow. A descriptive summary is included as Appendix A.

LOGRAM LANGUAGE

The format of the programming language of the TRW-130 may resemble that of a one-address computer. For example, to add the contents of a memory cell, noted symbolically G, to the accumulator, the programmer would write:

ADL G

In a conventional computer, the above statement would usually reside in a single memory cell. For the TRW-130, AD1 refers to the symbolic address of the first cell of the machine code which will effect an Add, Single Length function. The address of the operand, denoted G, appears in the next cell in sequence after AD1. Therefore, the TRW-130 program code appears in a vertical multi-word format, where each word contains an address.

AD1
G

The design of the TRW-130 stored logic computer will allow the use of a programming language like the single address example or we may have one, two, three or more address instruction sets. The programmer may use any one set or select single address lograms for certain operations, a two address logram for another operation and a three address logram for yet another operation; all within the same TRW-130 program. Regardless of the number of parameters, the first word of a logram calling sequence refers to the logram starting address (LSA) followed in sequence by the address of the operand(s) required to perform the prescribed function. The following sequence illustrates the general method.

| <u>Instruction Sequence</u> | <u>Contents of Y or (Y)</u> | <u>Indirect Contents of Y or ((Y))</u> |
|-----------------------------|-----------------------------|--|
| Y | LSA* | 1st logand of logram 1 |
| Y+1 | Address of 1st Operand | 1st Operand |
| Y+2 | Address of 2nd Operand | 2nd Operand |
| Y+3 | LSA | 1st logand of logram 2 |
| ... | ... | ... |
| etc. | | |

SYSTEM REGISTERS

The first 64 memory registers are described generally by the term "scratchpad." Notation for each scratchpad register begins with a dollar sign symbol (\$). The allocation of scratchpad registers, and the symbolic

*Program Starting Address

notation and usage of each scratchpad register is listed in Figure 1.

Accumulator and MQ

A pseudo-accumulator and MQ are included in scratchpad and are utilized as indicated below:

| | |
|---------------------------|--------------------------------------|
| Single Length Accumulator | \$AL |
| Single Length M.Q. | \$AR |
| Double Length Accumulator | \$AL |
| Double Length M.Q. | \$QL \$AR \$QR |

The Basic Logram Set provides for single, double, and in some cases, quadruple length operation. The third character of the instruction mnemonic (logram symbolic notation) is usually reserved to designate word length.

Instruction Counter

A pseudo-instruction counter, \$IC, contains the logram calling sequence address corresponding to the logram currently operating. It therefore serves as a tracing indicator and provides a linkage between successive lograms.

LOGRAM STANDARDS

An indirect addressing technique is used to pass control from logram to logram and to access logram operands. In order to maintain this linkage, certain standards must be adhered to:

Standard 1

The E, M, and P registers must be loaded upon entry to each logram, as follows:

E Register: The contents of the Logram Starting Address, contents of Y.

M Register: The Logram Starting Address, Y.

P Register: The next address in the logram calling sequence, Y+1.

Standard 2

Upon entry to a logram, the contents of the P register must be stored in the pseudo-instruction counter, \$IC. To satisfy Standard 1, it is necessary to execute a logand upon exit from each logram to load the E, M, and P registers as prescribed. If the address of the next logram is in the P register, the logand to execute is:

LP/DP/C/NØ

If the address of the next Logram Starting Address (LSA) is in the pseudo-instruction counter \$IC, the correct logand is:

LP/IL/\$IC

UNIVERSAL SCRATCHPAD ALLOCATION FOR THE AN/UYK-1 (TRW-130)

\$T1

DATA TYPE Fixed Point**ACCURACY:** 13 bits**RESTRICTIONS** Uses 66 cells of AT1TX Table.**DESCRIPTIVE INFORMATION**

DESCRIPTION AND FUNCTION: The value in \$AL is treated as a signed 14-bit fractional argument. The signed result is placed in \$AL in radians scaled 2^0 .

DATA TYPE Fixed Point

ACCURACY: 13 bits

RESTRICTIONS

DESCRIPTIVE INFORMATION

DESCRIPTION AND FUNCTION: The square root of \$AL, \$AR is placed in \$AL, \$AR. The scale of the root is one-half of the scale of the operand, which must be scaled evenly. The root is computed to 14 bits and other bits except leading zeros are meaningless.
