# WARRANTY

Notwithstanding any provision of any agreement the following warranty is exclusive:

The JOHN FLUKE MFG. CO., INC., warrants each instrument it manufactures to be free from defects in material and workmanship under normal use and service for the period of 1-year from date of purchase. This warranty extends only to the original purchaser. This warranty shall not apply to fuses, disposable batteries (rechargeable type batteries are warranted for 90-days), or any product or parts which have been subject to misuse, neglect, accident, or abnormal conditions of operations.

In the event of failure of a product covered by this warranty, John Fluke Mfg. Co., Inc., will repair and calibrate an instrument returned to an authorized Service Facility within 1 year of the original purchase; provided the warrantor's examination discloses to its satisfaction that the product was defective. The warrantor may, at its option, replace the product in lieu of repair. With regard to any instrument returned within 1 year of the original purchase, said repairs or replacement will be made without charge. If the failure has been caused by misuse, neglect, accident, or abnormal conditions of operations, repairs will be billed at a nominal cost. In such case, an estimate will be submitted before work is started, if requested.

THE FOREGOING WARRANTY IS IN LIEU OF ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS, OR ADEQUACY FOR ANY PARTICULAR PURPOSE OR USE. JOHN FLUKE MFG. CO., INC., SHALL NOT BE LIABLE FOR ANY SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES, WHETHER IN CONTRACT, TORT, OR OTHERWISE.

## If any failure occurs, the following steps should be taken:

1. Notify the JOHN FLUKE MFG. CO., INC., or nearest Service facility, giving full details of the difficulty, and include the model number, type number, and serial number. On receipt of this information, service data, or shipping instructions will be forwarded to you.
2. On receipt of the shipping instructions, forward the instrument, transportation prepaid. Repairs will be made at the Service Facility and the instrument returned, transportation prepaid.

## SHIPPING TO MANUFACTURER FOR REPAIR OR ADJUSTMENT

All shipments of JOHN FLUKE MFG. CO., INC., instruments should be made via United Parcel Service or "Best Way" \* prepaid. The instrument should be shipped in the original packing carton; or if it is not available, use any suitable container that is rigid and of adequate size. If a substitute container is used, the instrument should be wrapped in paper and surrounded with at least four inches of excelsior or similar shock-absorbing material.

## CLAIM FOR DAMAGE IN SHIPMENT TO ORIGINAL PURCHASER

The instrument should be thoroughly inspected immediately upon original delivery to purchaser. All material in the container should be checked against the enclosed packing list. The manufacturer will not be responsible for shortages against the packing sheet unless notified immediately. If the instrument is damaged in any way, a claim should be filed with the carrier immediately. (To obtain a quotation to repair shipment damage, contact the nearest Fluke Technical Center.) Final claim and negotiations with the carrier must be completed by the customer.

The JOHN FLUKE MFG. CO., INC., will be happy to answer all applications or use questions, which will enhance your use of this instrument. Please address your requests or correspondence to: JOHN FLUKE MFG. CO., INC., P.O. BOX C9090, EVERETT, WASHINGTON 98206, ATTN: Sales Dept. For European Customers: Fluke (Holland) B.V., P.O. Box 2269, 5600 CG, Eindhoven, The Netherlands.

\*For European customers, Air Freight prepaid.

**9010A Micro-System Troubleshooter**

## Section 1

# Introduction and Specifications

### WARNING

**THESE SERVICING INSTRUCTIONS ARE FOR USE BY QUALIFIED PERSONNEL ONLY. TO AVOID ELECTRICAL SHOCK, DO NOT PERFORM ANY SERVICING OTHER THAN THAT CONTAINED IN THE OPERATOR MANUAL UNLESS YOU ARE QUALIFIED TO DO SO.**

#### **1-1. THE 9010A INSTRUCTION MANUAL SET**

1-2. The Fluke Model 9010A Micro System Troubleshooter is documented by a set of three manuals and a reference guide, all described below:

##### **Operator Manual**

Provides instrument description and specifications, operating instructions including troubleshooting and test techniques, probe usage, execution of programs, options and accessories, and routine operator maintenance.

##### **Programming Manual**

Provides description of instrument programming capabilities; writing, editing, and execution of programs. Little or no experience is required to program the 9010A.

##### **Service Manual**

Provides specifications, theory of operation, troubleshooting, repair/maintenance information, disassembly procedures, a list of replaceable parts, and schematic diagrams. Intended for use by qualified service personnel.

##### **Reference Guide**

Quick-reference operating and programming information.

1-3. In addition, an Interface Pod Manual is provided with each interface pod. The pod manual contains the following information:

##### **Interface Pod Manual**

Provides specifications, microprocessor data, status and control line identification information, interface pod operating characteristics, theory of operation, troubleshooting procedures, disassembly information, a list of replaceable parts, and schematic diagrams.

#### **1-4. INSTRUMENT DESCRIPTION**

1-5. The 9010A Microsystem troubleshooter is a portable service instrument for testing and troubleshooting microprocessor-based equipment. The 9010A provides the following features:

- Keyboard selection of functions and operating modes.
- 32-character display for presentation of test results, operator messages, and prompts.
- Single-keystroke validation of electrical integrity of uP bus.
- Learn function for mapping UUT (unit under test) address space and identifying RAM, ROM, and I/O.
- Comprehensive, functional testing of RAM, ROM, and I/O.
- Nine troubleshooting functions for troubleshooting on or off the bus.

- On-line programming for development of system test and fault isolation programs.
- Consistent prompts and defaults for easy selection and specification of operations.
- Detailed error messages for locating UUT failures.
- Dual-function stimulus/response probe for generating bus-synchronized pulses or gathering signatures, counting events, and detecting logic levels.
- Hexadecimal keyboard for data entry.
- Sixteen 32-bit internal registers for storage and manipulation of data.
- Built-in cassette recorder for nonvolatile storage and transfer of test programs and data on minicassettes.
- Optional RS-232 port for remote communication.
- Optional interface pods for interfacing with most off-the-shelf microprocessors.
- UUT microprocessor emulation for execution of UUT program code.
- Rear-panel scope trigger output synchronized to UUT microprocessor bus events.

#### **1-6. LIST OF RECOMMENDED TEST EQUIPMENT**

1-7. Table 1-1 lists the test equipment required to complete the adjustment and troubleshooting procedures described in Section 4 of this manual. Equivalent equipment, if available, may be used in place of the recommended models.

#### **1-8. SPECIFICATIONS**

1-9. Specifications for the 9010A are listed in Table 1-2. The dimensions of the 9010A are shown in Figure 1-1.

**Table 1-1. Required Test Equipment**

<b>INSTRUMENT TYPE</b>	<b>RECOMMENDED MODEL</b>
Micro System Troubleshooter	Fluke 9010A
Interface Pod	Fluke 9000A-Z80
Digital Multimeter	Fluke 8020, 0.1%
Oscilloscope	Tektronix 485 or equivalent
Storage Oscilloscope	Tektronix 7623A w/7A18 plug-in
Variable Dc Power Supply	Any 0-10V Model

**Table 1-2. 9010A Specifications**

<b>DISPLAY</b> .....	32 character, 14 segment alphanumeric with decimal points.
<b>KEYBOARD FUNCTIONS</b>	
<b>Data Entry</b> .....	16-Key hexadecimal keyboard (0 through 9, A through F) for entering data.
<b>ENTER/YES</b> .....	Used for terminating expressions, responding to questions.
<b>CLEAR/NO</b> .....	Used for terminating expressions, responding to questions, deleting unwanted input.
<b>Mapping UUT Memory</b>	
<b>LEARN</b> .....	Locates and identifies RAM, and I/O read-write registers. Computes ROM signatures and identifies read/writable I/O bits.
<b>Viewing UUT Memory</b>	
<b>VIEW RAM, VIEW ROM, VIEW I/O</b> .....	Allows viewing or editing of UUT address space information.

**Table 1-2. 9010A Specifications (cont)**

<b>Functional Tests</b>	
BUS TEST .....	Checks electrical integrity of UUT microprocessor bus.
ROM TEST .....	Computes ROM signature and compares to specified ROM signature.
I/O TEST .....	Checks read-write capability of I/O registers.
RAM SHORT .....	Checks read-write capability and decoding of RAM locations.
RAM LONG .....	Checks bit pattern sensitive failures using an expanding checkerboard pattern on RAM locations as well as those tests performed by RAM short test.
AUTO TEST .....	Performs in sequence BUS TEST, ROM TEST, RAM SHORT and I/O TEST.
<b>Troubleshooting Functions</b>	
READ .....	Reads from UUT at an operator-specified address and reports value read.
WRITE .....	Writes operator-specified data to an operator-specified UUT address.
RAMP .....	Writes a binary incrementing pattern to an operator-specified UUT address.
WALK .....	Writes a rotating operator-specified bit pattern to the data lines at an operator-specified UUT address.
TOGGL DATA .....	Toggles an operator-specified data bit at a UUT address from one binary logic state to the other.
TOGGL ADDR .....	Toggles an operator-specified UUT address bit from one binary logic state to the other.
READ STS .....	Reads and displays the values of the UUT microprocessor status lines.
WRITE CTL .....	Writes operator-specified values to control lines on the UUT microprocessor bus.
TOGGL DATA CTL .....	Toggles an operator-specified control line from one binary logic state to another.
<b>Mode Controls</b>	
CONT .....	Continues an interrupted operation (operations are typically interrupted to report errors).
STOP .....	Halts current 9010A operation.
RPEAT .....	Repeats the previously performed 9010A operation once.
LOOP .....	Continuously performs the previous operation.
RUN UUT .....	Executes UUT program code beginning at an operator-specified address.
<b>Editing</b>	
MORE .....	Advances display to next line of information or next program step.
PRIOR .....	Scrolls display to previous line of information or prior program step.
<b>Test Sequencing</b> .....	Eight functions for entering or executing programs, and creating program messages, branches and loops.
<b>Arithmetic</b> .....	Eight functions for performing arithmetic on numeric quantities and manipulating data in registers.

**Table 1-2. 9010A Specifications (cont)**

<b>Selecting UUT-Specific Operations</b>	
SETUP .....	Allows the operator to select specific 9010A error detection and operating features to meet the requirements of a particular UUT.
<b>Cassette Tape Operations</b>	
READ TAPE .....	Reads information from cassette tape into 9010A memory.
WRITE TAPE .....	Writes information from 9010A memory onto cassette tape.
<b>Probe Controls</b>	
SYNC .....	Allows specification of probe synchronization to UUT bus events.
HIGH and LOW .....	Control generation of stimuli by the probe.
READ PROBE .....	Gathers response information at probe tip and displays signature, logic state history, and event count.
<b>RS-232 Interface Option Control</b>	
AUX I/F .....	Controls transfer of data over RS-232 Interface (if installed).
<b>CASSETTE TAPE</b>	Minicassettes store UUT memory map information, setup parameters, and program. Minicassette type: Verbatim.
<b>PROBE</b>	
<b>General</b> .....	Single-point stimulus and response probe.
STIMULUS .....	Pulse high, low, or toggle between high and low.
RESPONSE .....	Signature computation, logic states detected, event count.
<b>Stimulus Mode</b>	
<b>STIMULUS PULSE WIDTH</b>	
Address or data-valid sync .....	Equals address-valid or data-valid interval of the interface pod $\mu$ P.
Free-run .....	2 $\mu$ sec nominal.
<b>STIMULUS PULSE AMPLITUDE</b>	
High .....	>4V at +100 mA
Low .....	<0.2V at -100 mA
<b>Response Mode</b>	
<b>INDICATOR THRESHOLD</b>	
Logic High (Red) .....	>2.4V
Logic Low (Green) .....	<0.8V
Logic Tristate .....	<2.4V and >0.8V
<b>INDICATOR THRESHOLD ACCURACY</b> .	$\pm 0.2V$
<b>INDICATOR MINIMUM PULSE WIDTH</b>	
Logic High .....	>75 ns
Logic Tristate .....	>100 ns
Logic Low .....	>75 ns
<b>Maximum Safe Input Voltage at Probe Tip</b> .	-30V dc to +30V dc
<b>Probe Fuse</b> .....	The ground clip used with the probe is protected by a series-connected fuse located adjacent to the probe connector. A blown fuse is sensed by the 9010A and reported by a message on the display.

Table 1-2. 9010A Specifications (cont)

**9010A OPERATOR-ACCESSIBLE MEMORY**

**Tape-Transferable Memory** ..... Approximately 12k bytes for storage of UUT memory map information, Setup parameters, and programs. Contents may be transferred to and from cassette tape or transferred to and from a remote device via the RS-232 Interface Option.

**Registers** ..... Sixteen 32-bit registers.

**GENERAL**

**Power Requirements** ..... 100, 120, 220 or 240V ac  $\pm 10\%$   
50 or 60 Hz  $\pm 5\%$   
40 Watts maximum

**Size** ..... 11.7x38.7x31.1cm. (HXWXL) (4.6x15.25x12.25in.) See Figure 1-2.

**Weight** ..... 5 kg. (11 lb.)

**Environmental**

## STORAGE TEMPERATURE

Without Cassette Tape ..... -40 to +70°C (RH <95%)  
With Cassette Tape ..... +4 to 50°C (10% to 90% RH)

## OPERATING TEMPERATURE

Without Cassette Tape ..... 0 to 25°C (RH<95%)  
25 to 40°C (RH <75%)  
40 to 50°C (RH <45%)  
With Cassette Tape ..... 10 to 25°C (20% to 80% RH)  
25 to 30°C (20% to 73% RH)  
30 to 35°C (20% to 49% RH)  
35 to 40°C (20% to 32% RH)

*NOTE: All relative humidity (RH) conditions are non-condensing.*

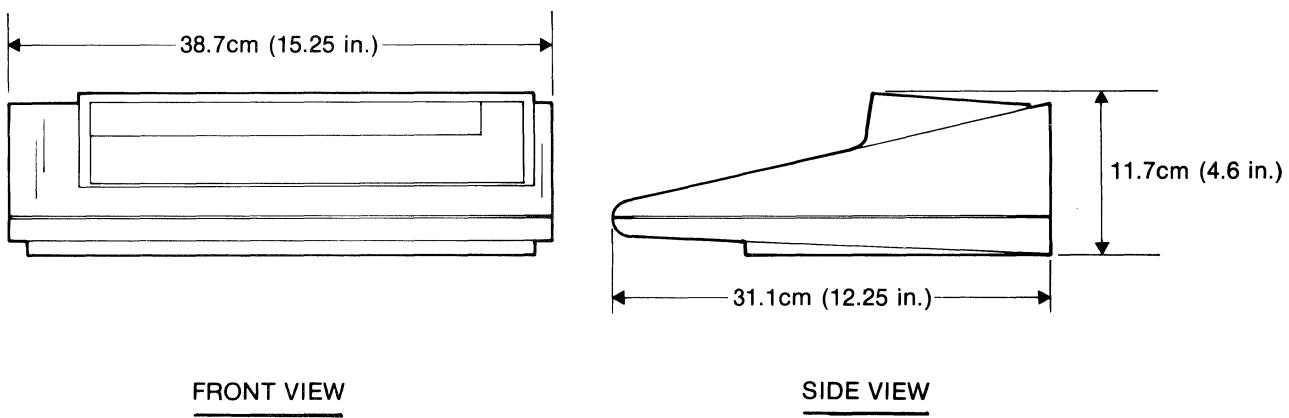

Figure 1-1. 9010A Outline Drawing

## Section 2

# Shipping and Service Information

### **2-1. SHIPPING INFORMATION**

2-2. The 9010A is packed and shipped in a foam-packed container. When you receive the 9010A, inspect the instrument thoroughly for possible shipping damage. Special instructions for inspection and claims are included with the shipping container.

2-3. If reshipment is necessary, use the original container. If the original container is not available, order a new one from John Fluke Mfg. Co., Inc. P.O. Box C9090, Everett, WA 98206. Telephone (206) 347-6100.

### **2-4. SERVICE INFORMATION**

2-5. Each Fluke Model 9010A Micro System Troubleshooter is warranted for a period of one year

upon delivery to the original purchaser. A copy of the WARRANTY is located at the front of this manual.

2-6. Factory authorized calibration and service for each Fluke product is available at various worldwide locations. Section 6 contains a complete list of these service centers. If requested, the customer will be provided with an estimate before any work begins on instruments that are beyond the warranty period.

### **2-7. QUESTIONS/PROBLEMS**

2-8. For additional information, contact the John Fluke Mfg. Co., Inc. at the address or telephone given in the Shipping Information.

## Section 3

# Theory of Operation

### **3-1. INTRODUCTION**

3-2. This section presents the theory of operation for the 9010A on a general block diagram level, followed by more detailed block diagram descriptions of each portion of the instrument.

### **3-3. OVERALL BLOCK DIAGRAM DESCRIPTION**

#### **3-4. Interface Pod Function**

3-5. The main function of the troubleshooter is to diagnose problems within any bus-oriented microprocessor based equipment. As shown in Figure 3-1, the troubleshooter is connected to the unit under test (UUT) via its microprocessor socket and a matching interface pod. The interface pod is compatible with the pin layout, the status/control functions, interrupt handling, and timing for the particular microprocessor employed by the unit under test.

3-6. In order to perform tests on a UUT, the troubleshooter issues commands and address information to the interface pod. Each troubleshooter command causes the microprocessor within the pod to execute a corresponding routine contained in its ROM. The routine, when executed within the interface pod, performs the commanded functions, such as a read or a write to the UUT at the specified address.

3-7. In short, the troubleshooter issues a basic command, and the interface pod performs the actual operation in a manner compatible with the microprocessor type employed by the UUT. For a complete description of interface pod operation, refer to the particular Interface Pod Manual.

#### **3-8. Troubleshooter Organization**

3-9. The troubleshooter is a microprocessor-based system, complete with 16K bytes of RAM and several I/O devices, including a magnetic tape unit and an optional communications interface. The general block diagram of

the instrument, presented in Figure 3-2, shows the internal organization of the instrument. The microprocessor initiates and controls all troubleshooter operations under the direction of firmware contained in ROM. The microprocessor views the RAM and ROM as memory devices, and views the following as I/O devices:

- Pod/Probe PIA (peripheral interface adapter)
- Display/Keyboard Assembly
- Signature Generator and Event Counter Circuit
- Magnetic Tape Controller
- RS-232 Interface (Option -001)

3-10. The microprocessor, in conjunction with the RAM, the ROM, the I/O selector, and the address and data buses, service each I/O device as required to:

- Issue commands and address data to the interface pod.
- Receive read data and status information from the interface pod.
- Receive keyboard data (operator commands) from the display/keyboard assembly.
- Send display data to the display assembly.
- Turn the probe pulse circuitry on or off.
- Receive signatures and/or event counts generated by the signature generator and event counter circuit from data at the probe tip.
- Write programs and test data stored in RAM to the magnetic tape unit for future use.

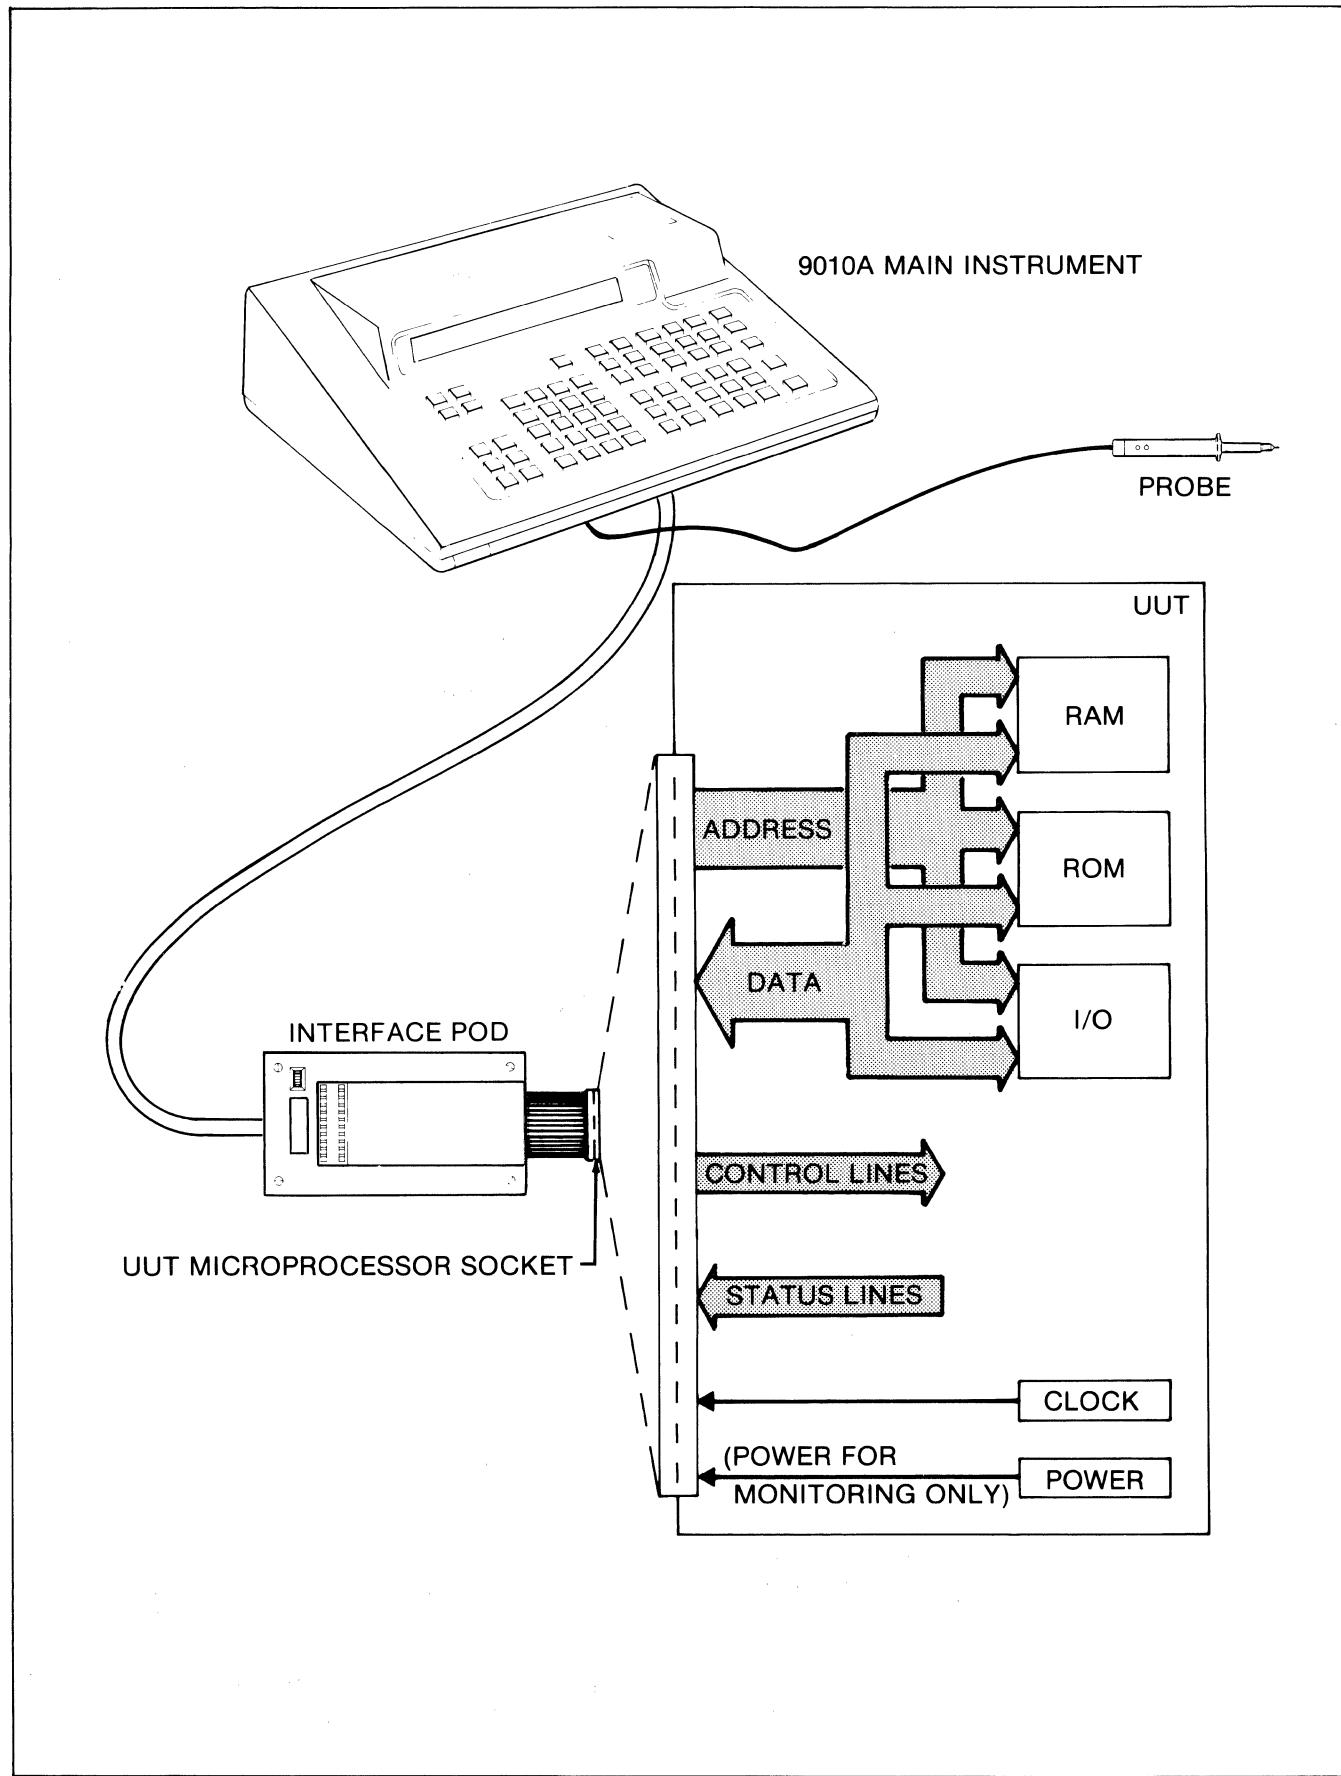

Figure 3-1. Connection of Troubleshooter to UUT

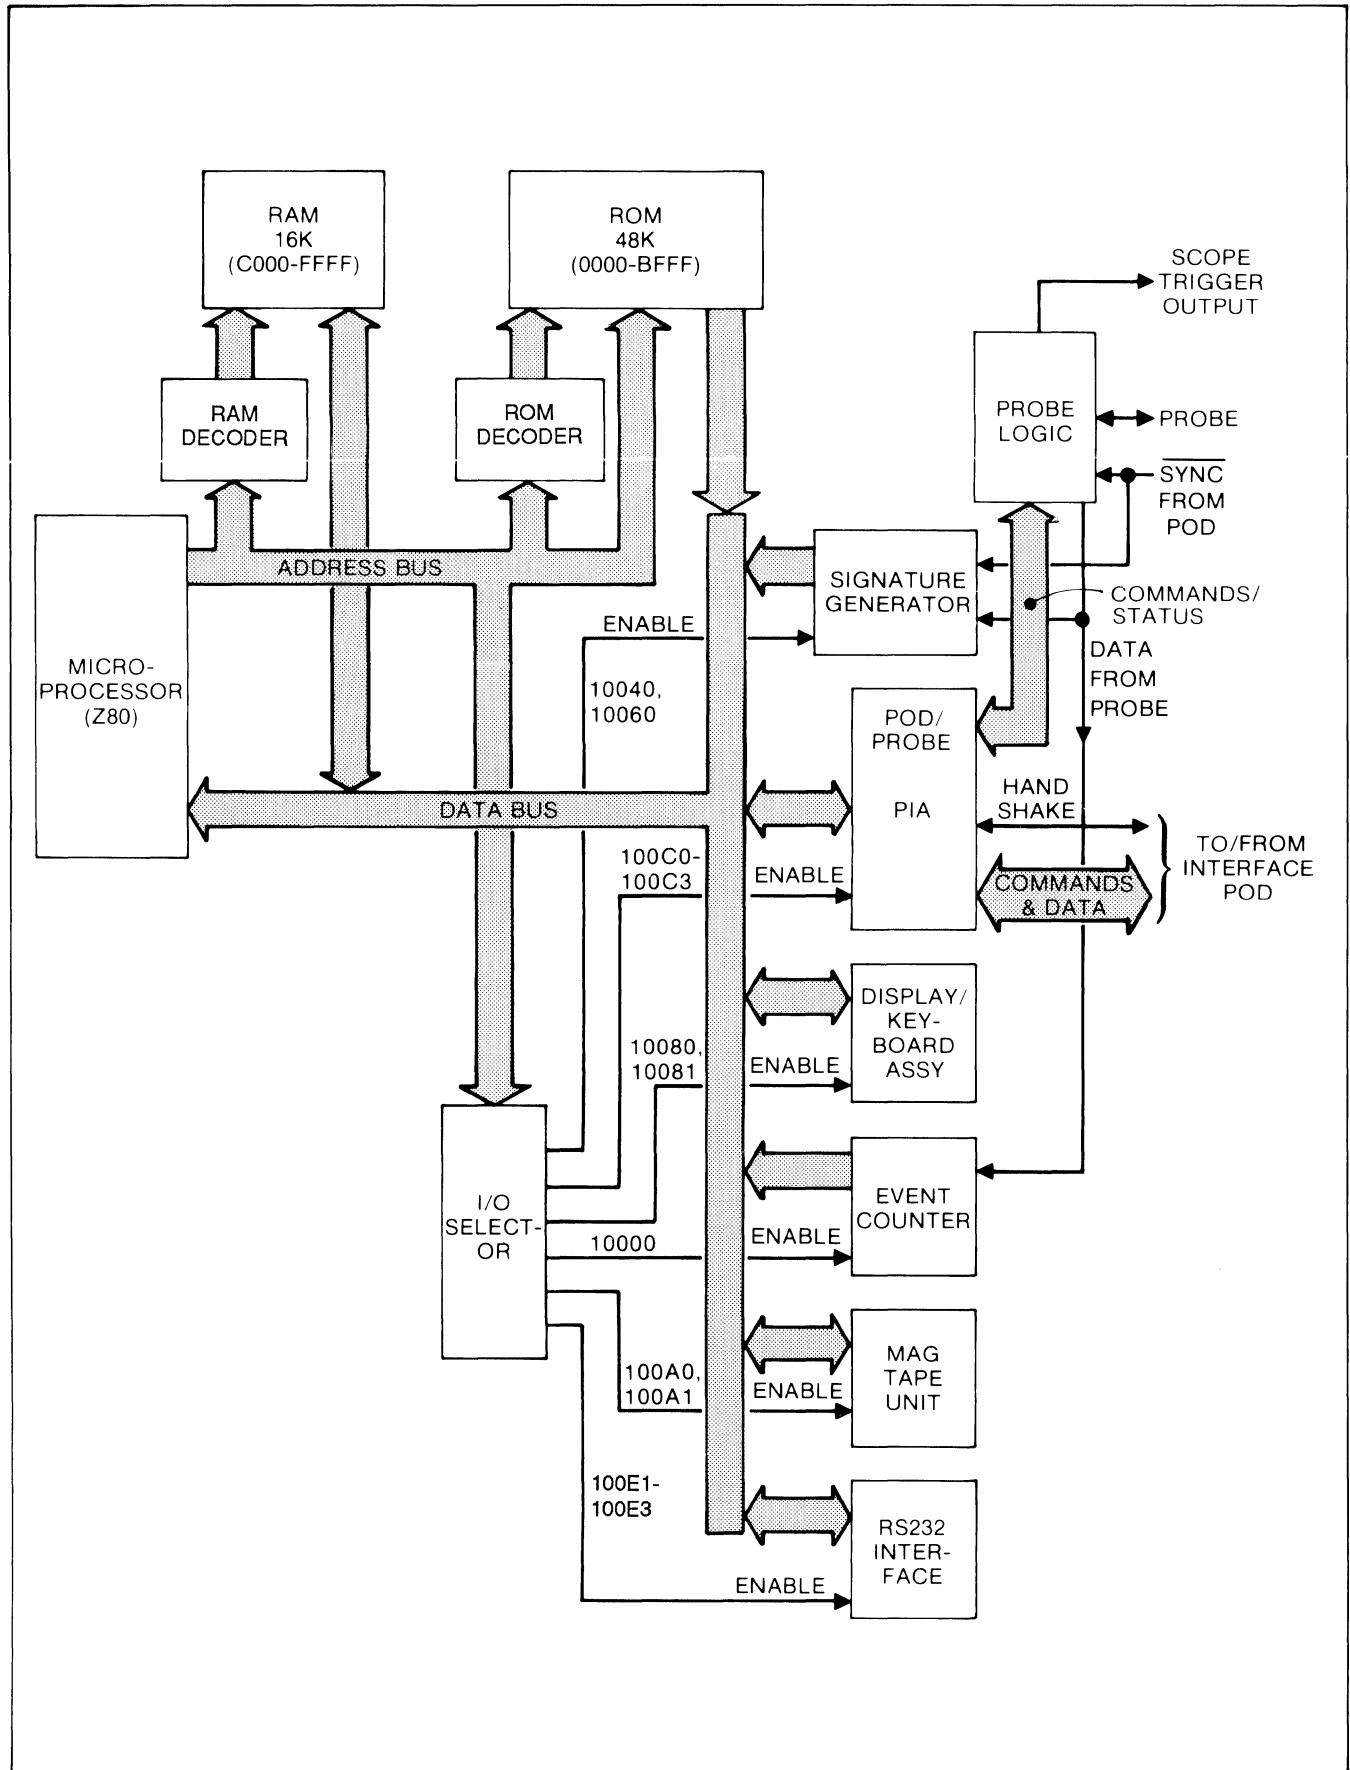

Figure 3-2. General Block Diagram

- Read programs and test data from the magnetic tape unit to RAM for immediate use.
- Send address space information, setup information, any or all programs, program numbers, or all information contained in tape-transferable memory to some remote device via the RS-232 interface.
- Receive data from a remote 9010A or computer via the RS-232 interface.

### **3-11. Immediate Mode Operation**

3-12. When operating the troubleshooter in the immediate mode, the microprocessor routinely addresses (by means of the I/O selector) the Display/Keyboard Assembly for keyboard commands initiated by the operator. When the operator presses a key, the Display/Keyboard Assembly generates an 8-bit byte of keyboard data which corresponds to the key pressed. When addressed by the microprocessor, the Display/Keyboard Assembly places the byte of keyboard data on the data bus. The microprocessor reads the keyboard data and determines the key pressed. The microprocessor then takes appropriate action by sending a corresponding message to the Display/Keyboard Assemblies and prepares to receive subsequent keyboard data from the same.

3-13. For example, when the operator presses the READ key, and the microprocessor routinely addresses the Display/Keyboard Assembly, the Display/Keyboard assembly places the 8-bit data byte corresponding to the READ key on the data bus. The microprocessor reads the 8-bit byte and determines that the READ key is pressed: it then sends the message READ @ — to the display, prompting the operator for address information.

3-14. As the operator enters the read address, the microprocessor reads each byte of address data at the Display/Keyboard Assembly. The microprocessor then assembles the read address by writing each byte to a designated portion of RAM. When the operator completes the entry of the read address and presses the ENTER key, the microprocessor assumes completion of address entry. The microprocessor then addresses the pod/probe PIA and issues a read command to the pod, using the address assembled from the operator entry. The pod accepts the read command and address data then performs the actual read operation with the UUT.

3-15. Shortly after issuing the read command to the pod via the pod/probe PIA, the microprocessor routinely addresses the pod/probe PIA for the response data (the data read at the UUT location specified in the read command). As the pod sends each byte of data, read from the UUT, to the pod/probe PIA, the microprocessor reads each byte and writes it to a designated portion of RAM. When the microprocessor completes the reading

of UUT data and writing to RAM, it addresses the Display/Keyboard Assembly and writes the data for display.

3-16. The preceding example illustrates general operation of the troubleshooter in the immediate mode. Most operations in the immediate mode are performed in a manner similar to that described for a typical read operation. As the operator presses specific keys in order to select specific functions, the microprocessor performs corresponding tasks in order to complete the functions.

### **3-17. Programming Mode Operation**

3-18. Operation of the troubleshooter in the programming mode is similar to that described for the immediate mode in that the operator presses specific function keys and enters data when prompted by the microprocessor display. Similarity of operation continues up to the point of pressing the ENTER key. When the operator presses the ENTER key to terminate entry of a command, the microprocessor stores the command in RAM as a step of a program instead of immediately issuing it to the interface pod. Execution of the stored step takes place when the program in which it resides is executed.

### **3-19. Executing Mode Operation**

3-20. Operation of the troubleshooter in the executing mode is similar to that described for the immediate mode except for the lack of keyboard function. In the executing mode, the microprocessor obtains commands and data previously stored in RAM as part of a program (during operation in the programming mode) instead of reading commands and data from entries made at the keyboard. The microprocessor executes each command stored in RAM as a step of a stored program.

### **3-21. Probe Logic Function**

3-22. The operator selects the mode of probe operation by pressing the appropriate keyboard keys (READ PROBE, HIGH, LOW, or SYNC). The microprocessor reads the key closures at the output of the display/keyboard assembly via the data bus in a manner similar to that described in Immediate Mode Operation. In response to the user selecting a probe function at the keyboard, the microprocessor addresses the appropriate port of the pod/probe PIA and writes the corresponding probe command to the probe logic. The probe logic decodes the probe command and causes the probe to produce high and/or low pulses, either synchronized or unsynchronized with pod operation.

3-23. In addition to generating pulses, the probe logic also receives input signals from the probe. It determines whether or not the voltages at the probe tip fall within certain valid limits (refer to the specifications for voltage detection threshold) and lights the probe lamps accordingly.

3-24. A data byte which indicates the logic level at the probe tip, or any invalid voltage condition, is sent by the probe logic to the appropriate port of the pod/probe PIA. The microprocessor reads the data byte applied to the pod/probe PIA port, after execution of a READ PROBE command, and determines the logic state at the probe tip (high, low, or invalid). The microprocessor then writes the appropriate message to the display/keyboard assembly for display to the operator.

### **3-25. Signature Generator/Event Counter Function**

3-26. The signature generator receives the signal data read by the probe and, in conjunction with the SYNC pulse from the pod, applies these signals to the data and clock inputs of the signature shift register. As a result, the shift register generates a signature unique to the incoming probe signal. The event counter maintains a running total of high-to-invalid transitions (events) read by the probe.

3-27. Pressing the READ PROBE key causes the microprocessor to address (by means of the I/O selector) the signature generator and event counter circuit and reads their contents. The microprocessor then writes the current contents to a designated portion of RAM (register 0). With the signature and event count stored in RAM, the microprocessor resets the signature generator and event counter circuit permitting the next read probe operation to accumulate and yield new probe data. If the read probe operation was performed in the immediate mode, the microprocessor also sends new probe-tip state data, probe signature, and event count data to the Keyboard/Display Assembly for display to the operator.

### **3-28. Magnetic Tape Controller Function**

3-29. The Magnetic Tape Controller controls the magnetic tape unit in response to commands from the microprocessor. The Magnetic Tape Controller contains a peripheral microcomputer which, under internal software control, performs the following functions:

- Reads to or writes from the tape.
- Controls tape direction and speed.
- Rewinds tape.
- Positions tape at load point.
- Formats write words.
- Decodes read words.
- Detects end of tape.
- Detects cassette present/not present.
- Detects write-protected cassette.

- Detects synchronization errors.
- Reports magnetic tape controller status to the main microprocessor.

### **3-30. RS-232 Interface Function (Option -001)**

3-31. The RS-232 Interface provides an EIA RS-232-C compatible bidirectional interface to the troubleshooter with selectable baud rates of 110, 150, 300, 600, 1200, 4800, and 9600. The interface is isolated from the troubleshooter and meets all RS-232 requirements for bidirectional movement of serial data. The RS-232 Interface provides communications to and from other 9000 series troubleshooters or other RS-232 compatible devices. Refer to Section 6 for the description of the RS-232 Interface.

### **3-32. DETAILED BLOCK DIAGRAM DESCRIPTION**

#### **3-33. Introduction**

3-34. The following paragraphs describe operation of the troubleshooter at a detailed block diagram level. Each description includes a block diagram which can be related to the schematic diagrams contained in Section 8.

#### **NOTE**

*Memory and I/O devices are controlled by addresses and, in some cases, by data. Table 4-13 lists controlling addresses and data.*

### **3-35. Control Section**

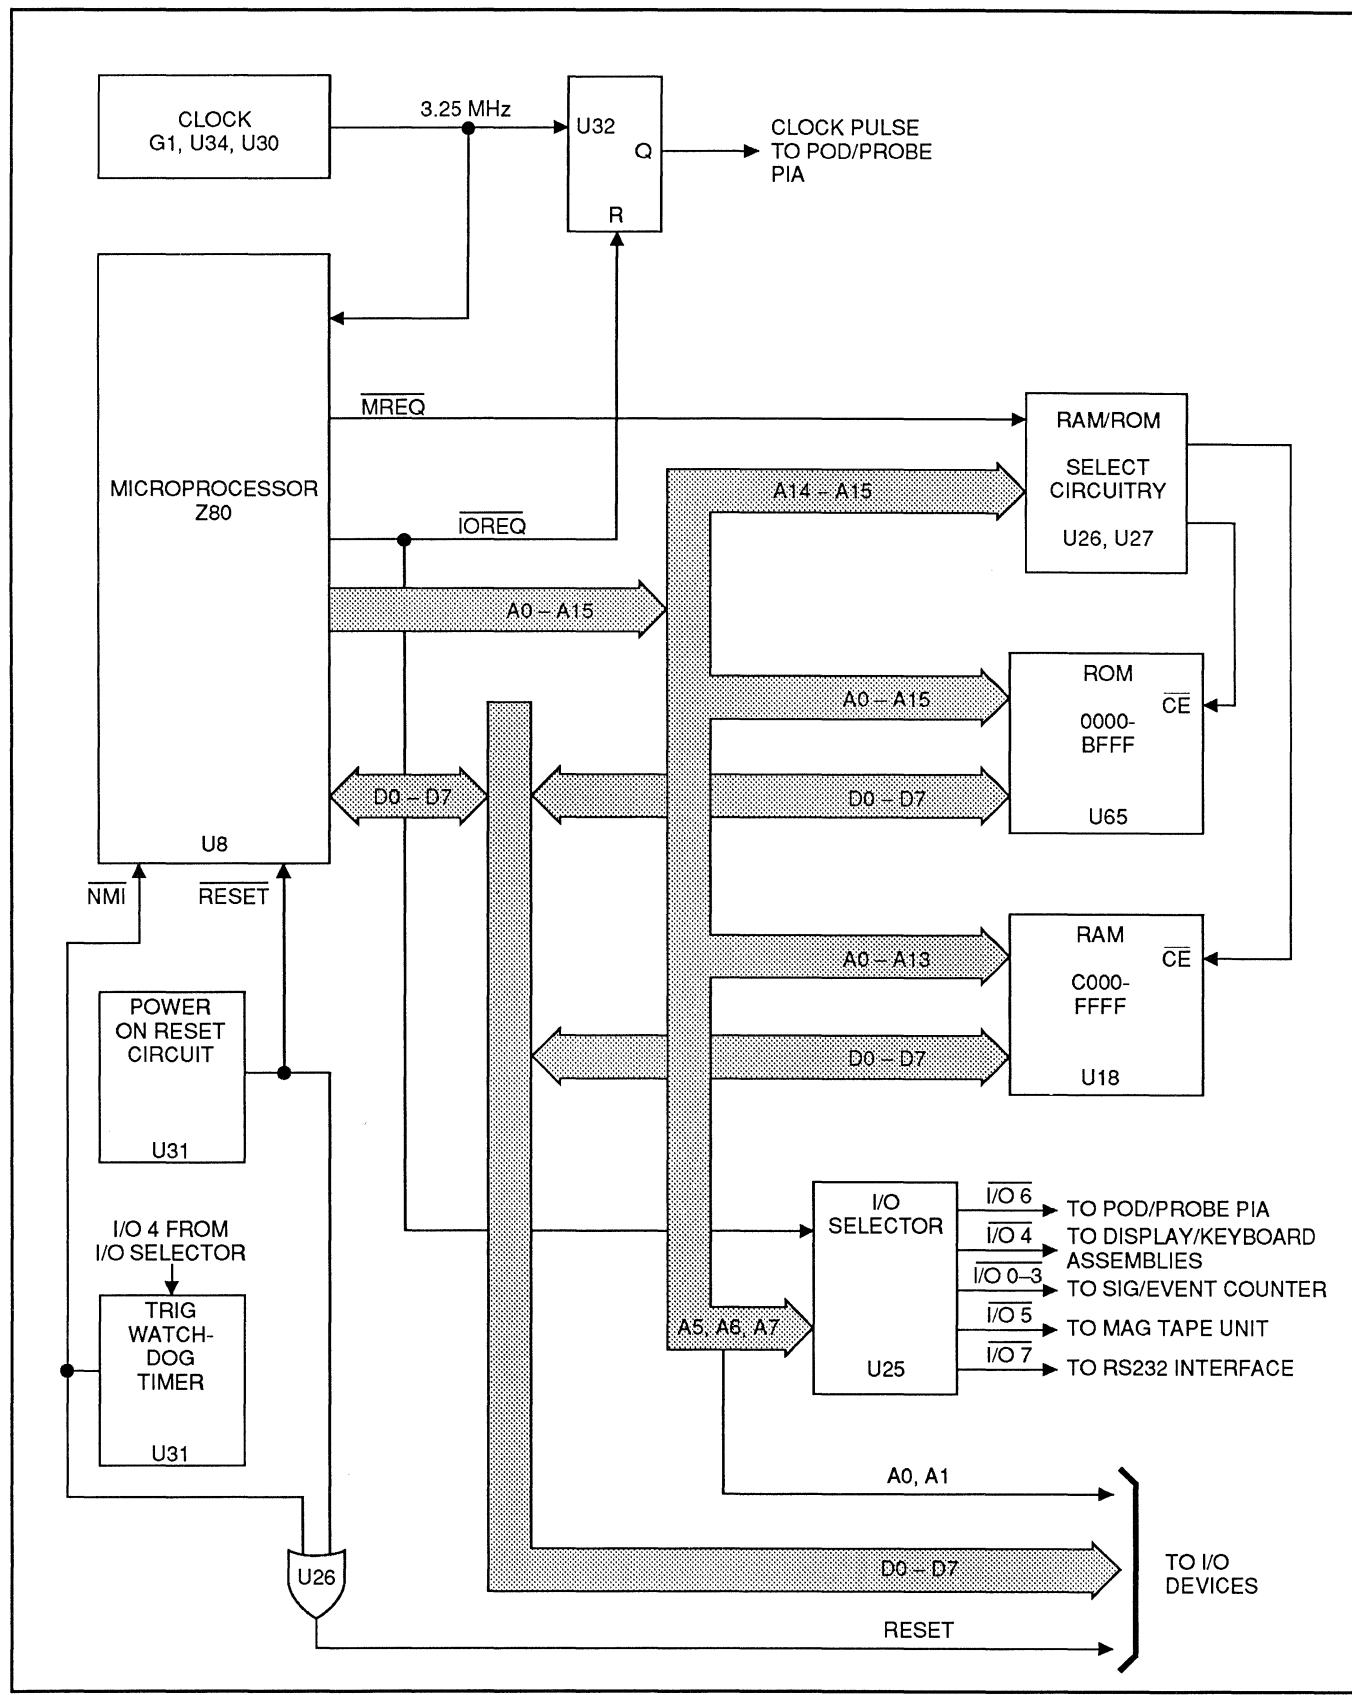

3-36. The control section of the troubleshooter, shown in block diagram Figure 3-3, contains the clock, the microprocessor, RAM, ROM, power-on reset circuit and watchdog timer, and an I/O selector. The control section operates as a small computer system to initiate and control, by means of software contained in ROM, all troubleshooter and interface pod functions.

### **3-37. CLOCK CIRCUIT**

3-38. The clock circuit, made up of G1, U34 and U30, provides timing control for the troubleshooter. The clock circuit contains a 6.5 MHz oscillator, the output of which is divided by two to produce a 3.25 MHz output. The 3.25 MHz is buffered and fed to the microprocessor, and flip-flop U32. (Flip-flop U32 produces a clock pulse to drive the pod/probe PIA each time an I/O operation takes place. Refer also to the pod/probe PIA description.)

### **3-39. I/O SELECTOR**

3-40. Several portions of the troubleshooter are viewed by the microprocessor as I/O devices, and are addressed and serviced accordingly. Portions of the troubleshooter which appear as I/O devices are:

- Display/Keyboard Assembly
- Pod/Probe PIA
- Signature Generator and Event Counter
- Magnetic Tape Unit
- RS-232 Interface (Option -001)

3-41. As indicated in the lower portion of Figure 3-3, each I/O device connects to the data bus (D0 - D7), address line A0, and also to the Reset line. In addition, each I/O device receives an enable signal from the I/O selector, U25, except the signature generator and event counter circuit which may receive any one of four enable signals. (Refer to Table 4-13 for specific I/O addresses.)

3-42. The I/O selector is a 3-to-8 line decoder which accepts address bus lines A5, A6, and A7 when enabled by the low I<sub>OREQ</sub> (I/O request) output of the microprocessor. Whenever the microprocessor performs an I/O operation, it places the device address on the address bus and pulls the I<sub>OREQ</sub> output low. The I/O selector produces an output to select the addressed I/O device. While selected, the I/O device can receive and/or send data over the data bus as directed by the microprocessor. Each I/O device also receives the RESET signal from the power-on reset circuit and watchdog timer.

#### 3-43. POWER-ON RESET CIRCUIT

3-44. The power-on reset circuit controls the resetting (initializing) of the microprocessor and each I/O device when power is applied to the troubleshooter. The power-on reset circuit consists of a one-shot which, upon the application of instrument power, generates a RESET and RESET signal. The RESET signal is fed to the RESET input of the microprocessor, and is fed via U26 to each I/O device.

#### 3-45. WATCHDOG TIMER

3-46. The function of the watchdog timer is to detect any abnormal operation of the troubleshooter and, if abnormal operation occurs, interrupt the microprocessor and reset each I/O device. The watchdog timer, a re-triggerable one-shot, receives the I<sub>O4</sub> output from the I/O selector to the Display/Keyboard Assembly. As long as the troubleshooter is operating normally, addressing of the Display/Keyboard Assembly takes place at a frequency sufficient to keep the watchdog timer in the triggered state.

3-47. However, if a problem develops which prevents normal troubleshooter operation, addressing of the Display/Keyboard Assembly, and consequently the I<sub>O4</sub> signal, will typically cease or become infrequent. As a

result of the missing I<sub>O4</sub> signals, the watchdog timer times out before being retriggered, to produce a RESET signal to each I/O device (via U26), and an NMI (non-maskable interrupt) signal to interrupt the microprocessor. When interrupted, the microprocessor initiates a self test sequence to verify operation and writes the appropriate message to the Display/Keyboard Assembly.

#### 3-48. Display/Keyboard Assembly

3-49. The Display/Keyboard Assembly operates as a complete subsystem of the control section to:

- Receive display data from the control section.
- Decode ASCII characters into 14-segment character codes.
- Continually refresh the troubleshooter display including annunciators.
- Monitor the keyboard for switch closures.
- Translate key closures into appropriate ASCII codes.
- Place keyboard data on the data bus.

3-50. The microprocessor in the control section transmits display data to this subsystem as necessary to create the appropriate troubleshooter messages, and frequently polls for keyboard data. As shown in Figure 3-4, the main elements of the Display/Keyboard Assembly include:

- An 8-bit peripheral microcomputer, U1
- A 32-character display, V1
- A 32-bit character shift register, U3 - U6
- Segment shift registers, U13 and U14
- Segment drivers, U11 and U12
- A keyboard, A3
- An 8-bit row shift register, U2
- A set of annunciator latches, U15
- A set of annunciators, DS1 - DS5
- Filament drive circuit, U16, U17, Q1 and Q2

3-51. The troubleshooter display is a 14-segment, 32-character, vacuum fluorescent display having 14 commonly-connected segment and one decimal point enable lines and 32 individual character select lines. To

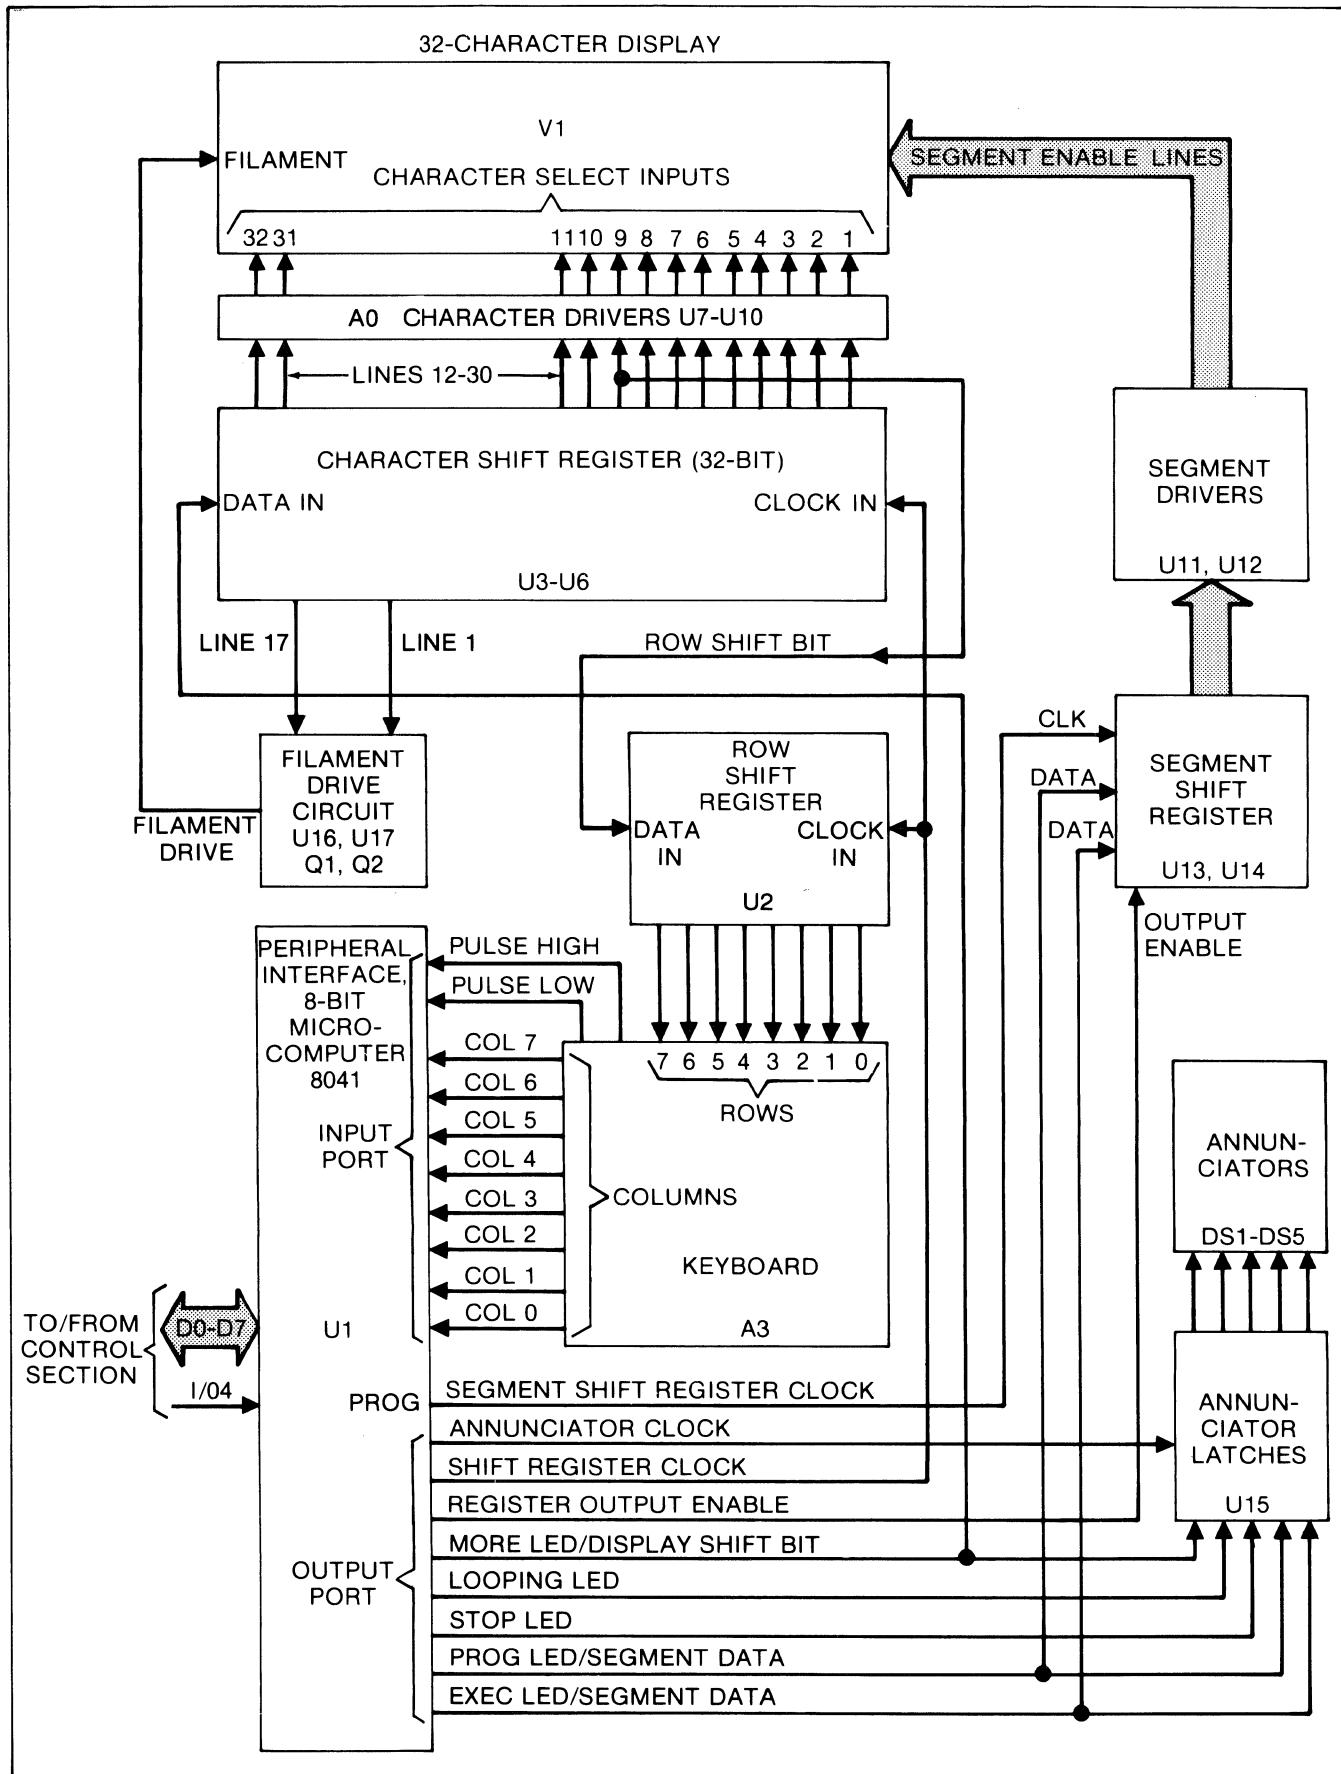

Figure 3-4. Display/Keyboard Assemblies

display a particular digit, letter, or symbol at a particular position on the 32-character display, the segment lines corresponding to the desired digit, letter or symbol are enabled and the desired display character selected. The individual characters of the display are sequentially selected by the outputs of a 32-bit shift register, referred to as the character shift register. The character shift register is driven by the peripheral microcomputer, which writes first to both the data input and clock input, and then 31 times to the clock input only, all via its output port. The 32 writes to the character shift register cause one bit to shift completely through the register, sequentially selecting each character position of the display.

3-52. Between each of the 32 writes to the character shift register, the peripheral microcomputer writes the segment and decimal point data (to the segment shift register) which is to be displayed at the next character position of the display. Once the segment shift register is loaded, the peripheral microcomputer writes an Output Enable signal to gate the segment data to the display segments.

3-53. The peripheral microcomputer refreshes the display at a 61.5 Hz rate while also controlling the annunciators (MORE, LOOPING, STOPPED, PROGMING, and EXECUTING) and polling the keyboard for operator commands. The peripheral microcomputer selectively turns each of the five annunciators on by writing a low to the corresponding input of annunciator latches, U15. The control section microprocessor provides the data which determines the particular latches written to, while the peripheral microcomputer U1 controls the flashing of the annunciators by writing and clocking high and low inputs to the latches.

3-54. The peripheral microcomputer receives keyboard commands by routinely polling its input port. The input port is connected to the columns of the 8-by-8 keyboard matrix. The rows of the keyboard matrix are connected to the outputs of the row shift register, U2. The row shift register is clocked by the same peripheral microcomputer output used to clock the character shift register. The row shift register receives a single bit of data at its input each time the character shift register selects character position 9 of the display. The result of this activity is that the keyboard rows are sequentially enabled once each time the character shift register cycles through the 32 display character position.

3-55. Whenever a particular row is enabled and a keyboard key is pressed, the column corresponding to that key produces an input to the input port of the peripheral microcomputer. Since the peripheral microcomputer controls which row is enabled and receives the column information directly from the keyboard, it determines the key pressed and places a

corresponding byte of keyboard data on the data bus. The control section microprocessor routinely polls the peripheral microcomputer for keyboard data and, from such data, determines the key pressed at the keyboard.

3-56. The display assembly also contains a filament drive circuit consisting of a set-reset flip-flop and drive transistors. The filament drive circuit alternates the polarity of the display V1 filament each time display characters 1 and 17 are selected by the character shift register. As a result, the polarity of the filament alternates twice per display refresh, to provide an average of six volts to the filament with no gradient across the tube. This is necessary to prevent a varying light output intensity over the length of the tube.

#### *NOTE*

*Refer to Table 4-13 for a list of display assembly protocol (address and command data).*

#### **3-57. Pod/Probe PIA**

3-58. The pod/probe PIA (peripheral interface adapter) provides interface of the probe logic to the control section, and also of the interface pod to the control section. As shown in Figure 3-5, the PIA connects to the control section by means of the data bus and part of the address bus. The PIA also receives control signals from the RD line of the microprocessor, the IOREQ line of the microprocessor, and the I/O selector (via flip-flop U34).

3-59. The two I/O ports of the PIA are connected to the probe logic and to the interface pod. Each port is bidirectional and separately addressable by means of address lines A0 and A1. To command the probe logic, the microprocessor first addresses and writes to the I/O port A control register. (This is necessary in order to address either the I/O port A data direction register or I/O port A data buffer within the 6520 PIA, since both have the same address.) The microprocessor then writes to the I/O port A data direction register to set lines PA5, PA6, and PA7 as outputs. The microprocessor again addresses the I/O port A control register (this time to permit addressing of the I/O port A data buffer), followed by a write to the I/O port A data buffer to place data on lines PA5, PA6, and PA7 as required to control the probe logic. Refer to Table 4-13 for addresses and write data which perform pod/probe PIA functions.

3-60. To receive data from the probe logic, the microprocessor addresses and writes to the I/O port A control register (to permit addressing the I/O port A data direction register). A subsequent write to the I/O port A data direction register sets lines PA5, PA6, and PA7 as inputs. The microprocessor again addresses the I/O port A control register (to permit addressing the I/O port A data buffer) followed by a read to the I/O port A data

buffer to receive the data placed on lines PA5, PA6, and PA7 by the probe logic.

#### *NOTE*

*The function of the PA5, PA6, and PA7 lines is described in the subsequent probe logic description.*

#### **3-61. Pod Communication**

3-62. The control section communicates with the interface pod by sending commands, and receiving data in response to the commands. The transmission of commands and reception of data is mediated by two handshake lines labeled MAINSTAT and PODSTAT.

3-63. To command the interface pod, the microprocessor first addresses and writes to the I/O port A control and data direction registers to set line PA0 (MAINSTAT) as an output. The microprocessor then addresses and writes to the I/O port A control register and data buffer to set line PA0 low and create the MAINSTAT signal. The interface pod responds to the MAINSTAT signal by developing the PODSTAT output signal. The microprocessor, after writing the MAINSTAT signal, again writes to the I/O port A control and data direction registers to set the PA1 line as an input. With the PA1 line set as an input, the microprocessor writes to the I/O port A control register and then reads at the port A data buffer. When the PODSTAT signal appears (PA1 goes low), the microprocessor proceeds to write data to the interface pod using the control register, data direction register, and the data buffer of I/O port B. Refer to Figure 3-6 for MAINSTAT and PODSTAT signal details, and to Table 4-13 for a list of pod/probe PIA addresses and commands.

3-64. During PIA operation, the PIA R/W line controls data direction from the microprocessor, the data bus provides or receives the data, and lines A0 and A1 select control register or data direction register/data buffer of I/O ports A and B. The previously described control section provides clock pulses via U32, and the PIA is chip selected by the I/O selector, with some delay provided by flip-flop U34.

#### **3-65. Probe Logic**

3-66. The probe logic, shown in the block diagram Figure 3-8, provides the following functions:

- Receiving and interpreting logic pulses from the probe tip and reporting their condition to the microprocessor.
- Lighting the probe lamps in accordance with the logic signals appearing at the probe tip.
- Providing probe tip signals to the signature generator and event counter circuit.

- Providing high and/or low logic signals to the probe tip as directed by the microprocessor.
- Generating a differentiated pod Sync pulse for application to an oscilloscope as an external trigger signal.

#### **3-67. RECEIVING PROBE TIP SIGNALS**

3-68. High, low, and invalid signals applied to the probe tip are fed to an input of the probe logic as indicated in Figure 3-7. A network made up of R25, R26, C51 and C52 provides probe compensation, while Q1 provides high input and low output impedances. A pair of level detectors, one to detect logic high levels (U36/U41), and one to detect logic low levels (U49/U41), receive the incoming signals from the probe tip. The high level detector produces a output for the duration of logic high signals ( $>+2.4$  volts), while the low level detector produces a output for the duration of logic low signals ( $<+0.8$  volts). During signals of invalid levels (+0.8 to 2.4 volts), neither level detector produces an output.

#### **3-69. SYNCHRONIZED/FREE-RUNNING OPERATION**

3-70. The sync select flip-flops, U37, and 2:1 multiplexer, U38, permit selection of synchronized or free-running probe operation. Synchronized operation allows the troubleshooter to detect only probe levels which exist at the time the interface pod terminates the SYNC signal (refer to the interface pod manual for Sync signal details). Free-running operation allows the troubleshooter to detect probe levels asynchronously with respect to pod operations.

3-71. Signals from the high and low level detectors are fed both through and around the sync select flip-flops to two sets of multiplexer, U38, inputs. The signals from the high level detector are also fed as SIG Data (signature data) over to the signature generator data input and event counter clock input. One set of multiplexer inputs receives the levels latched into the sync flip-flops at the termination of the interface pod SYNC signal. This set of multiplexer inputs is used during operation in the synchronized mode of probe operation.

3-72. The other set of multiplexer inputs receives signals produced by the high and low level detectors, and corresponds to the free-running mode of probe operation. Selection of either multiplexer input for connection to its output is made by the Sync Control signal fed from the input control latch, U45. The input control latch receives a synchronize or free-running command from the microprocessor via the pod/probe PIA and line PA7.

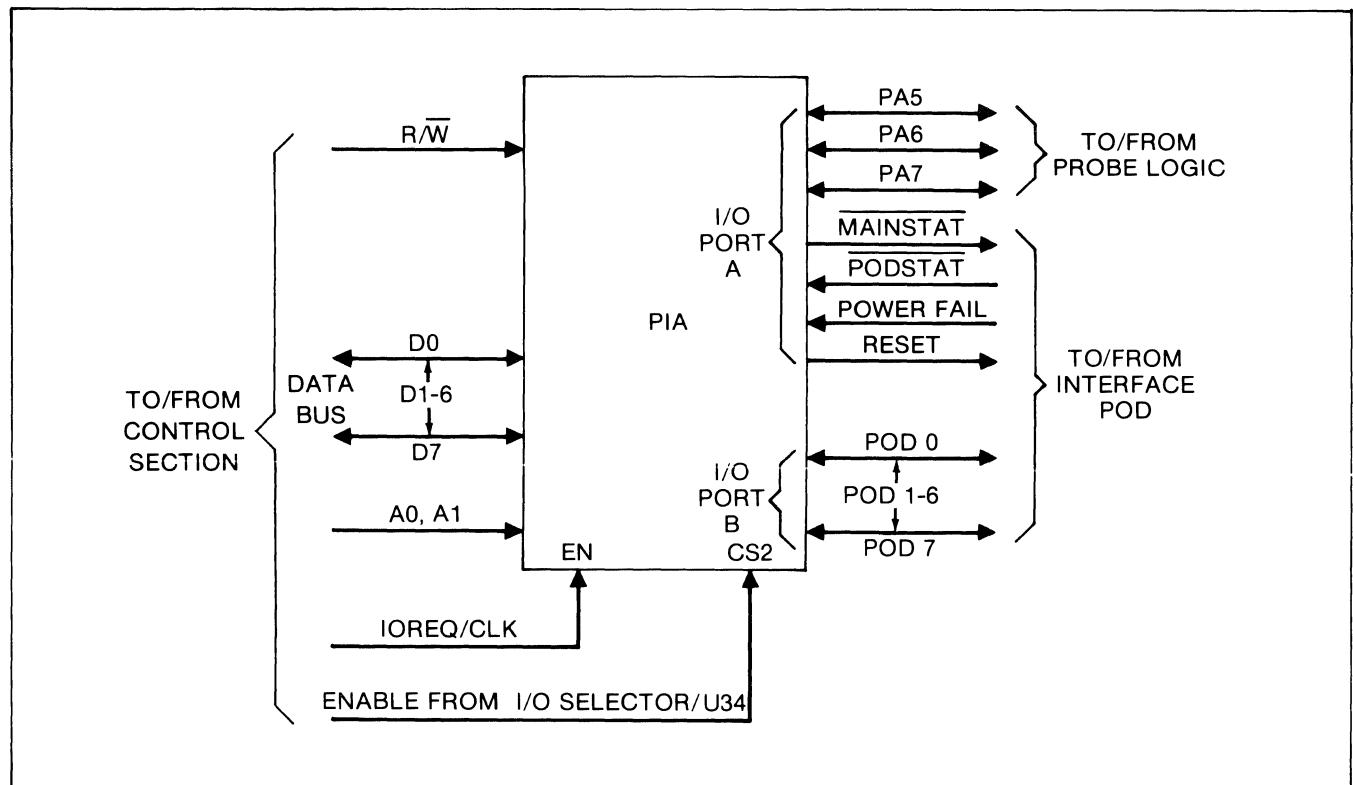

Figure 3-5. Pod/Probe PIA Signals

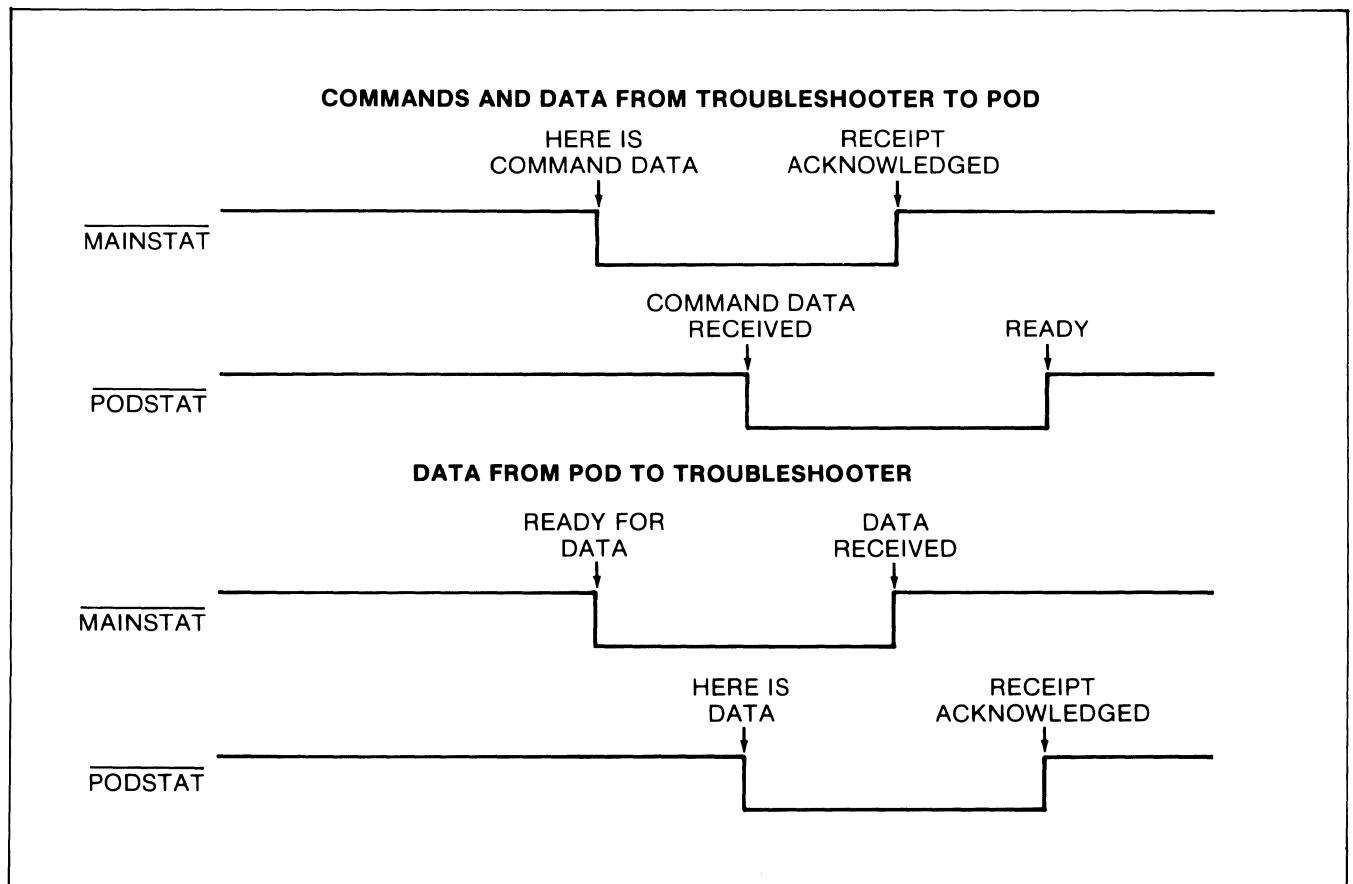

Figure 3-6. MAINSTAT/PODSTAT Signals

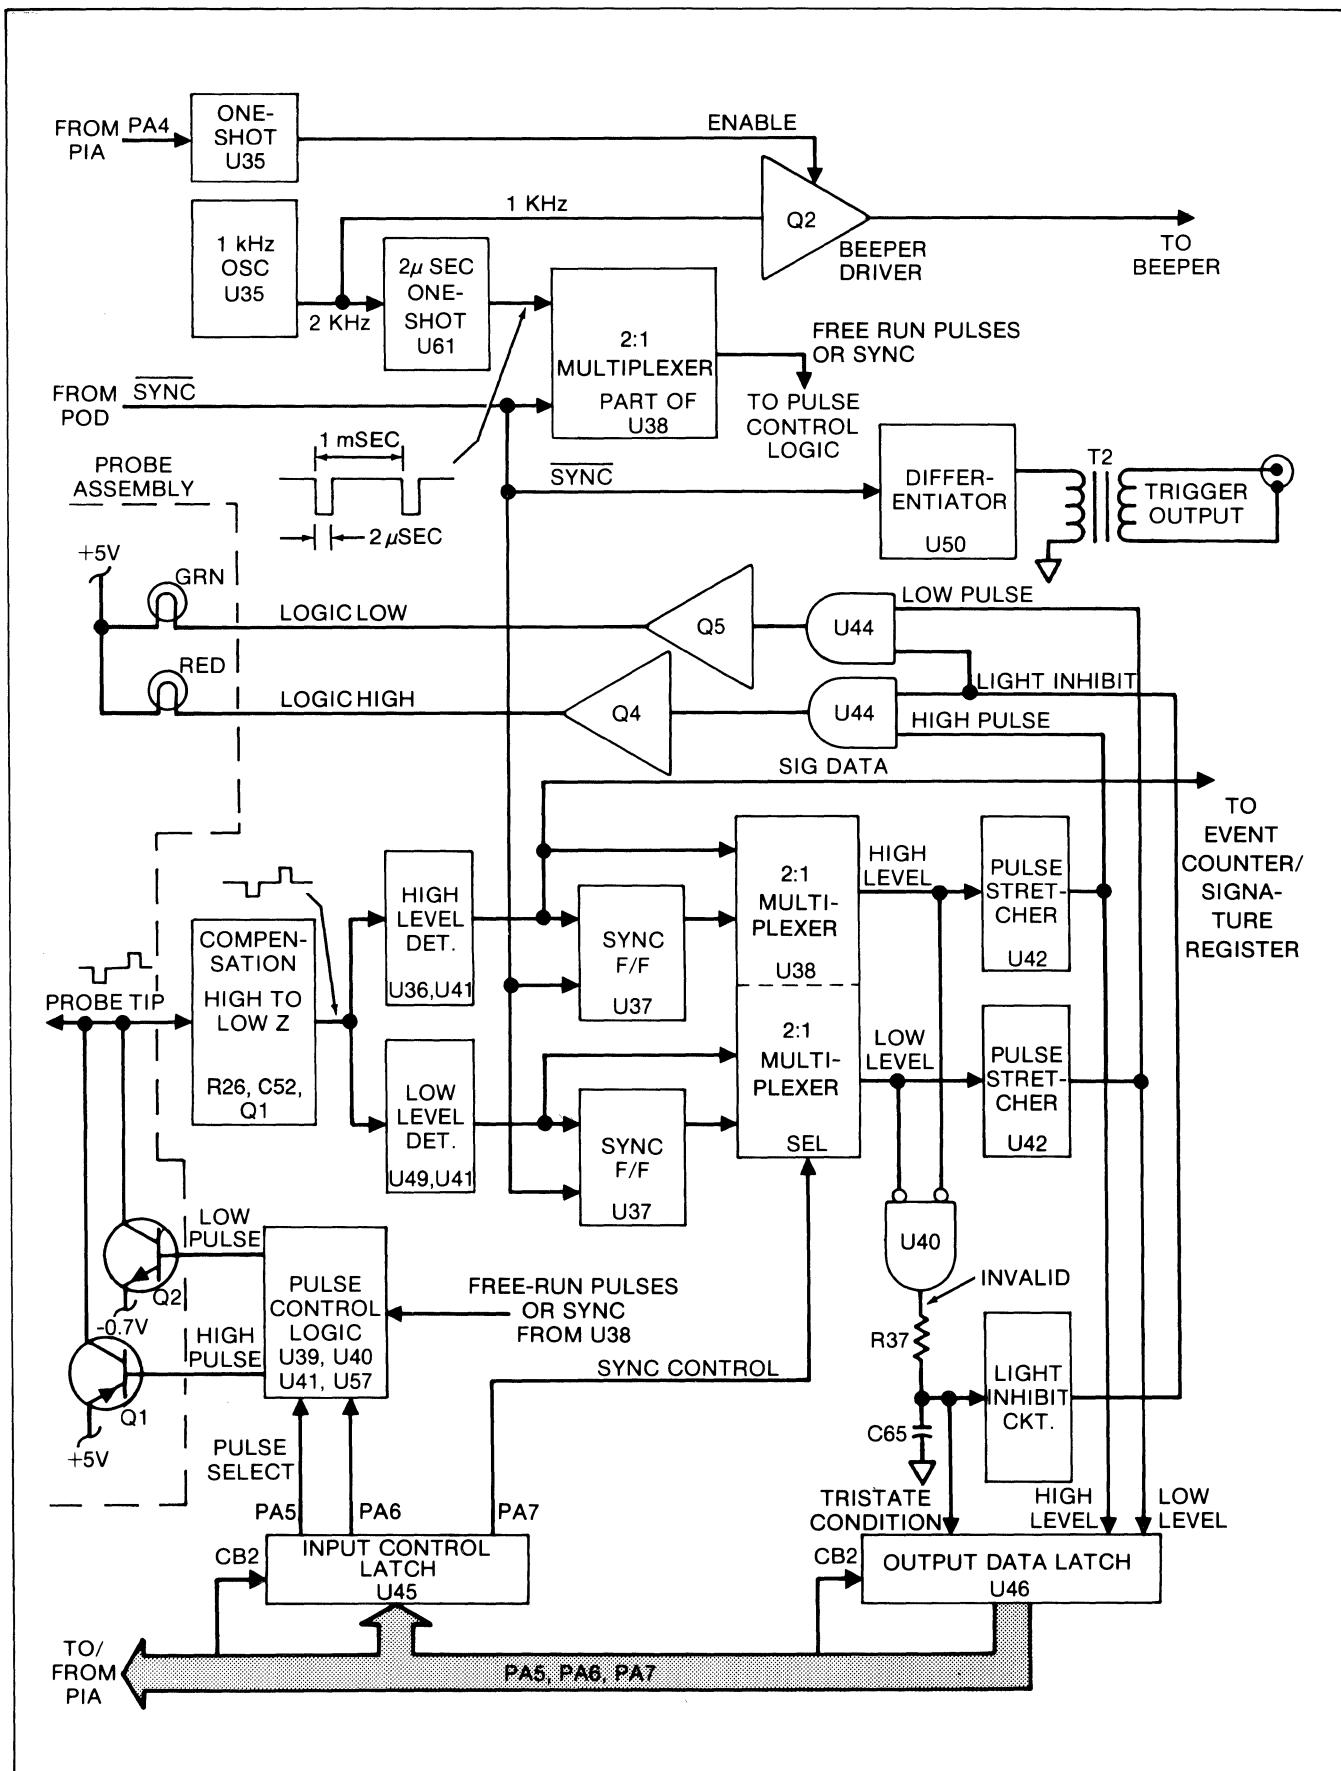

Figure 3-7. Probe Logic

### 3-73. PROBE LAMP CONTROL

3-74. The probe contains two lights, one green and one red, which are driven by Q5 and Q4 in conjunction with U44 and pulse stretchers (one-shots), U42. The pulse stretchers have a 200 millisecond duration and provide a means of making probe pulses of short duration visible on the probe indicator lights. Probe pulses of longer than 200 millisecond duration are fed around the one-shots and override their outputs. This arrangement allows pulses of short duration to be visible on the indicator lights for 200 milliseconds, and also allows pulses longer than 200 milliseconds to be visible for their entire duration. When the probe receives a logic high level, the red light glows, and when the probe receives a logic low level, the green light glows.

3-75. Signals, which are neither valid logic high nor valid logic low, cause the probe lights to go off. When an invalid level appears at the probe, neither the high level detector U36/U41 nor the low level detector U49/U41 provide an output. As a result, the outputs of the 2:1 multiplexer are both low. Gate U40 detects the lack of multiplexer outputs and produces a high output to the light inhibit circuit, U39/U43, via the integrator formed by R37 and C65. The integrator prevents the light inhibit circuit from responding to invalid signals having a duration of approximately 100 nanoseconds or less. Since a normal TTL edge can spend up to about 10 nanoseconds in the invalid region, the transitions will not cause the lights to flash.

3-76. The light inhibit circuit consists of two one-shots, each triggered at the occurrence of an invalid signal, the first having a duration equal to one-half (100 milliseconds) that of the second (200 milliseconds). The output of the second one-shot inhibits the input to the first so that an invalid signal triggers the first one-shot only as long as the second one-shot has returned to its stable state. As long an invalid signal is present at the integrator, the first one-shot continues to be triggered, producing a 100 millisecond pulse every 200 milliseconds. The output of the first one-shot is the output of the light inhibit circuit.

3-77. The output of the light inhibit circuit enables gates U44 when invalid signals are less than about 100 nanoseconds in duration, but inhibits them for 100 milliseconds when invalid for longer than approximately 100 nanoseconds. Since U44 directs the outputs of the pulse stretchers to line drivers Q4 and Q5, the lights are turned off whenever the light inhibit circuit produces an output pulse, causing one or both lights to flash at a 5 Hz rate.

3-78. During a steady invalid signal, the light inhibit signal produces 100 millisecond pulses at the 5 Hz rate, but the lights stay off due to the lack of outputs at the pulse stretchers.

### 3-79. PROBE FUSE SENSING

3-80. The ground path for the probe contains a fuse, F2. A sensing circuit, shown in Figure 3-8, detects failure of the fuse and/or connection of the probe ground lead to any positive or negative supply. Normally, the probe ground lead ties to ground via fuse F2. However, when an overload condition causes failure of F2, the ground lead goes to +5 volts due to a pull-up resistor (R4) contained in the probe. The +5 volts turns Q3 on to produce the FB (fuse blown) signal fed to the event buffer shown in Figure 3-9. The microprocessor reads the contents of the event buffer during the read probe operation, and examines the FB (fuse blown) bit for a blown fuse condition. If the FB line is low, the blown probe fuse messages appear on the troubleshooter display.

3-81. If the probe ground lead is connected to a negative supply, the fuse blows, but Q3 remains off due to the negative voltage at its base. In this case, Q6 turns on to produce the low FB signal and notify the microprocessor of the blown fuse condition.

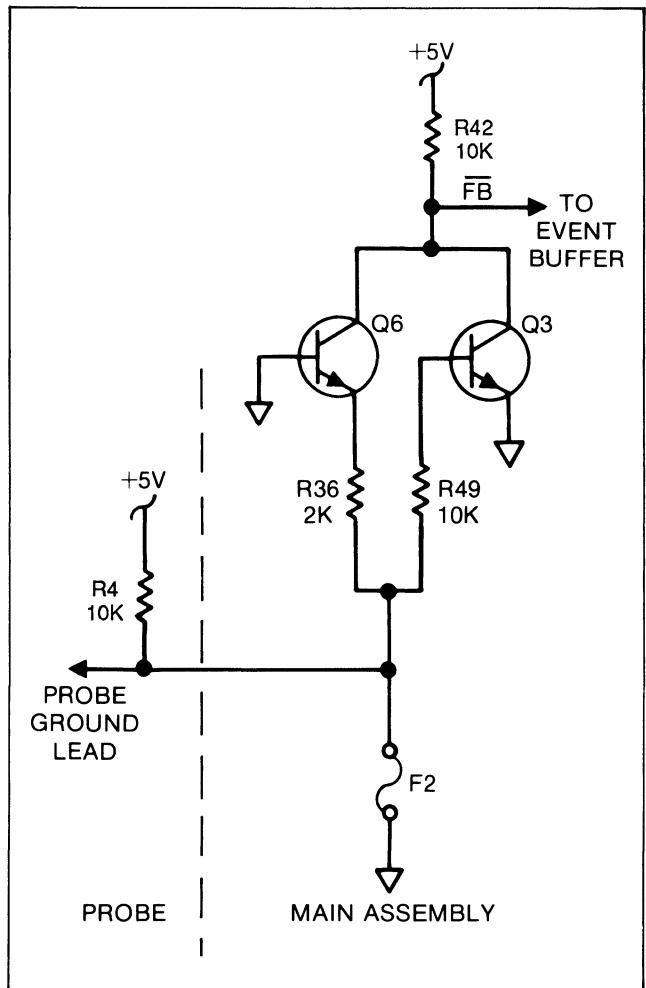

Figure 3-8. Probe Fuse Sensing Circuit

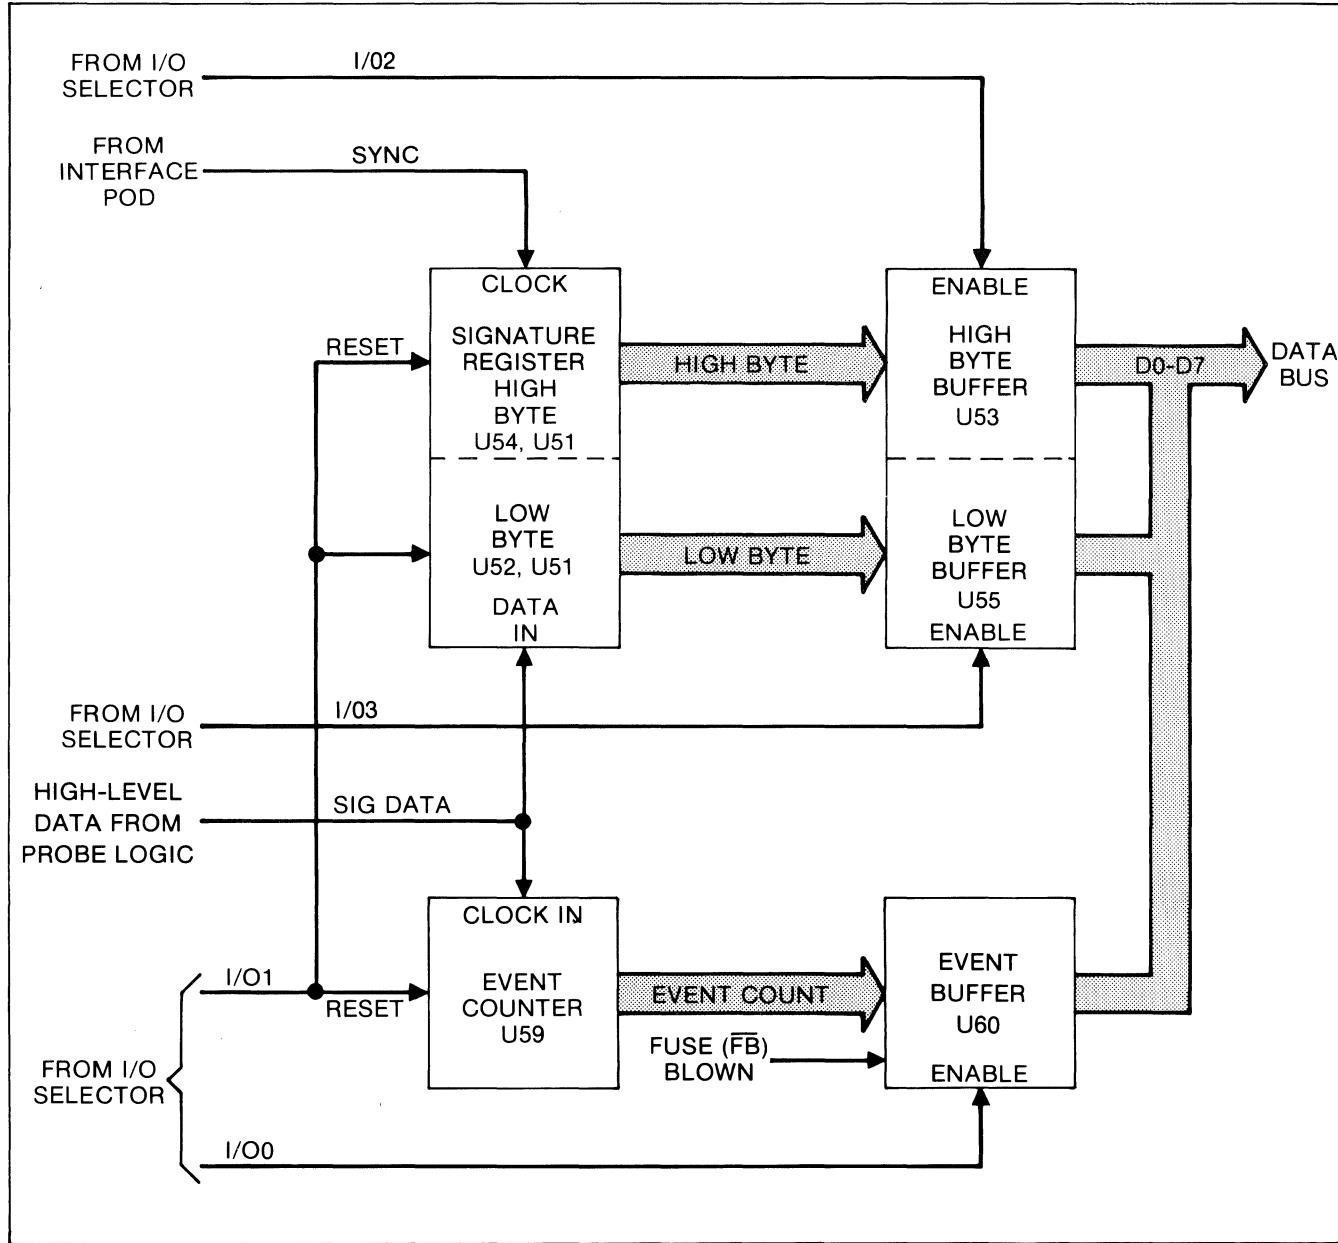

Figure 3-9. Signature Register/Event Counter

### 3-82. PROBE STATUS REPORTING

3-83. The probe logic reports the result of probe operations to the microprocessor by indicating the occurrence of logic high, logic low, and invalid signals. The occurrence of a logic high and/or logic low signal causes an output at one or both of the pulse stretchers. The pulse stretcher outputs are connected to respective inputs of the output data latch, U46. The occurrence of a 100 nanosecond or greater invalid signal causes an input to the light inhibit circuit, and also to an input of the output data latch. The output data latch stores its inputs and, when enabled by the CB2 signal from the pod/probe PIA, places the stored high, low, and/or invalid signal condition on PIA lines PA5, PA6, and PA7. The

pod/probe PIA operates under microprocessor control to place the probe signal condition data on the microprocessor data bus.

#### NOTE

*The invalid state goes unreported when operating in the synchronized mode. This is due to the controlling software and not the hardware.*

### 3-84. PROBE PULSE GENERATION/CONTROL

3-85. The probe logic generates pulses, either synchronized to the interface pod or free-running at 1 kHz, high or low, for application via the probe to a UUT.

Synchronized probe pulses are derived from the Sync signal (generated by the interface pod at valid address/data times), while free-running pulses are derived from a 1 kHz-oscillator/2-microsecond one-shot combination. Each probe pulse source connects to an input of a third section of the 2:1 multiplexer, U38 (described previously under Synchronized/Free-Running Operation). The Sync Control signal fed from input control latch, U45, makes selection of either multiplexer input for connection to the output. The input control latch receives a synchronize or free-running command from the microprocessor via the pod/probe PIA and line PA7.

3-86. For synchronized pulses, the multiplexer selects the SYNC signal for application to the pulse control logic (U39, U40, U41, U57). For free-running pulses, the multiplexer selects the 1 kHz-oscillator/one-shot output for application to the pulse control logic. The 1 kHz oscillator output triggers a 2 microsecond one-shot to produce a continuous stream of 2 microsecond pulses at a 1 KHz rate.

3-87. The pulse control logic accepts either SYNC pulses from the interface pod or 2 microsecond pulses from the 1 kHz-oscillator/one-shot, and accepts pulse select signals from input control latch, U45. Pulse select signals provided by U45 originate with the microprocessor and are written to the pod/probe PIA, and then to the input control latch via PIA lines PA5 and PA6.

3-88. Flip-flop U57, of the pulse control logic, in conjunction with the PA5 and PA6 signals from the PIA, allow the probe to pulse high, pulse low, or alternate between high and low by means of transistor switches Q1 and Q2, contained in the probe. The width of the output pulse is 2 microseconds for free-running mode, and equal to the pod SYNC pulse in the synchronized mode.

### 3-89. SCOPE TRIGGER OUTPUT

3-90. The probe logic includes a differentiator/amplifier circuit, U50, which provides negative-going and positive-going pulses at a rear panel-mounted BNC connector. These pulses, intended for application to the trigger input of an oscilloscope, result from the negative-going and positive-going edges of the interface pod SYNC signal, and as a result, are coincident with the SYNC signal. A pulse transformer provides output coupling to the rear panel connector and isolates the scope ground (tied to earth ground) from the system ground.

### 3-91. Signature Generator and Event Counter

3-92. The signature generator consists of a pair of clocked shift registers (U52 and U54) equipped with exclusive-OR (U51) feedback to produce a unique four-digit (16-bit) hexadecimal signature. The signature

generator utilizes the high-level data provided by the probe logic for data input, and the SYNC signal provided by the interface pod for the signature clock input. The traditional start and stop signature times are controlled from the execution of a read probe function within a 9010A user program.

3-93. As shown in Figure 3-9, the SIG Data signals provided by the high level detector of the probe logic are fed to the data input of the signature register. The Sync signal from the interface pod is applied to the clock input. As a result, any logic state appearing at the probe tip at the time of the SYNC signal (trailing edge) affects the state of the signature register. The timing of the SYNC and probe signals, in conjunction with the exclusive-OR feedback allows the signature register to produce unique signatures at different UUT test points. Since the signature register is clocked only by each interface pod-produced UUT event, the probe signature is always synchronized to interface pod/UUT activities regardless of the sync selected by the front panel SYNC key.

3-94. The high byte and low byte buffers (U53 and U55) receive the signature from the register and gate it, one byte at a time, onto the data bus as commanded by the microprocessor. The I/O2 signal from the I/O selector gates the high byte of signature data onto the data bus; the I/O3 signal gates the low byte.

3-95. The event counter U59 produces a seven-bit count (0-127 with wrap-around) of logic high-to-invalid transitions appearing at the probe tip. The input to the event counter is provided by the SIG Data signal from the high level detector of the probe logic. The event buffer, U60, gates the seven-bit event count plus the one-bit fuse-blown (FB) indication onto the data bus in response to the I/O0 signal from the I/O selector as commanded by the microprocessor.

3-96. The microprocessor resets both the signature generator and the event counter by means of the I/O1 output of the I/O selector. Reset occurs at the beginning of all read probe operations.

### 3-97. Magnetic Tape Controller

#### 3-98. INTRODUCTION

3-99. The Magnetic Tape Controller provides control of the magnetic tape unit in response to commands from the microprocessor. The Magnetic Tape Controller contains a peripheral microcomputer which, underinternal software control, performs the following functions:

- Reads to or writes from the tape.
- Controls tape direction and speed.

- Rewinds tape.
- Positions tape at load point.
- Formats write words.
- Decodes read words.
- Detects end of tape.
- Detects cassette present/not present.
- Detects write-protected cassette.
- Detect synchronization errors.
- Reports tape subsystem status to the microprocessor.

**NOTE**

*Refer to Table 4-13 for a list of addressing protocol for the magnetic tape controller.*

3-100. Selection (addressing) of the Magnetic Tape Controller by the microprocessor is done by means of the I/O5 output of the I/O selector described earlier in this section. In addition, address line A0 provides the controller with two addresses. When the microprocessor writes A0 low, the information placed on the data bus is for a read data or write data operation, as determined by the RD or WR lines. However, when A0 is written high, a write operation issues a command to the peripheral microcomputer to place controller status on the data bus. The peripheral microcomputer also receives the system RES signal generated by the power-on reset and watchdog timer circuits. Refer to Figure 3-10 for a block diagram of the magnetic tape controller.

### 3-101. TAPE DRIVE MOTOR CONTROL

3-102. A speed-regulated reel-drive motor moves the magnetic tape over the read/write head. To operate the motor in the forward direction, the peripheral microcomputer writes an output to the Forward line (and also an output to the  $\bar{E}$  line to enable all controller functions). The Forward signal operates the switch formed by U4B to connect the positive side of the tape drive motor to the +5 volt supply. As a result, motor current flows through U4B, through the motor, and out through back-EMF regulator, U6. The back-EMF regulator senses the voltage across the motor, which is proportional to motor speed, and provides the feedback necessary to maintain a constant motor speed. Potentiometer R14 provides a means of setting motor speed.

3-103. To operate the motor in the rewind direction, the peripheral microcomputer writes an output to the REWD line, and also to the  $\bar{E}$  line. The REWD signal turns on solenoid driver, U4A, to actuate the rewind solenoid, closes the switch formed by U4C, and closes the switch formed by U4D and Q1. As a result, motor current flows from the +5 volt supply through U4C, bypasses U6, flows through the motor and through Q1 to the ground. Since regulator U6 is bypassed, motor rewind speed is uncontrolled and is the maximum provided by five volts.

### 3-104. WRITE CONTROL

3-105. To avoid any possible errors which might result from tape jitter or speed variation, a method of ratio encoding is used to write all data on the tape. Figure 3-11 illustrates the method of ratio encoding employed by the magnetic tape controller. Any data bit is either 2/3 bit time high or low, with the other 1/3 bit time of the opposite polarity. A one bit begins low, and after 1/3 of the bit time makes a transition to high for the remaining 2/3 of the bit time. A zero bit also begins low, but stays low for 2/3 of the bit time, after which it makes a transition to high for the remaining 1/3 of the bit time. Under this coding scheme, the first 1/3 of a bit is always low, and the last 1/3 of a bit is always high. An extra 1/3 low provides a stop mark, and an inter-word high of 1-2/3 bit times is written for synchronization purposes. A high for ten word lengths indicates end-of-file.

3-106. To write to the tape, the peripheral microcomputer writes a WE (write enable) signal to current sources Q3 and Q4, and to current sinks U3A and U3B. The WE signal turns on the current sources and enables the current sinks. To write a high to the tape, the peripheral microcomputer writes to the WRITE 1 line to turn on current sink, U3A. When turned on, U3A directly sinks the current supplied by Q4, and also sinks the current supplied by Q3 after passing through the read/write head in a negative-to-positive direction.

3-107. The read/write head records the transition as a flux change on the tape. To write a low to the tape, the peripheral microcomputer writes to the WRITE 0 line to turn on current sink, U3B. When turned on, U3B directly sinks the current supplied by Q3, and also sinks the current supplied by Q4 after passing through the read/write head in a positive-to-negative direction (opposite to the direction when writing a high level). The read/write head records the transition as a flux change on the tape, but of the opposite polarity of that recorded for the high portion of a data bit.

### 3-108. PLAYBACK AMPLIFIER

3-109. All signals appearing across the read/write head, including those written by the peripheral microcomputer,

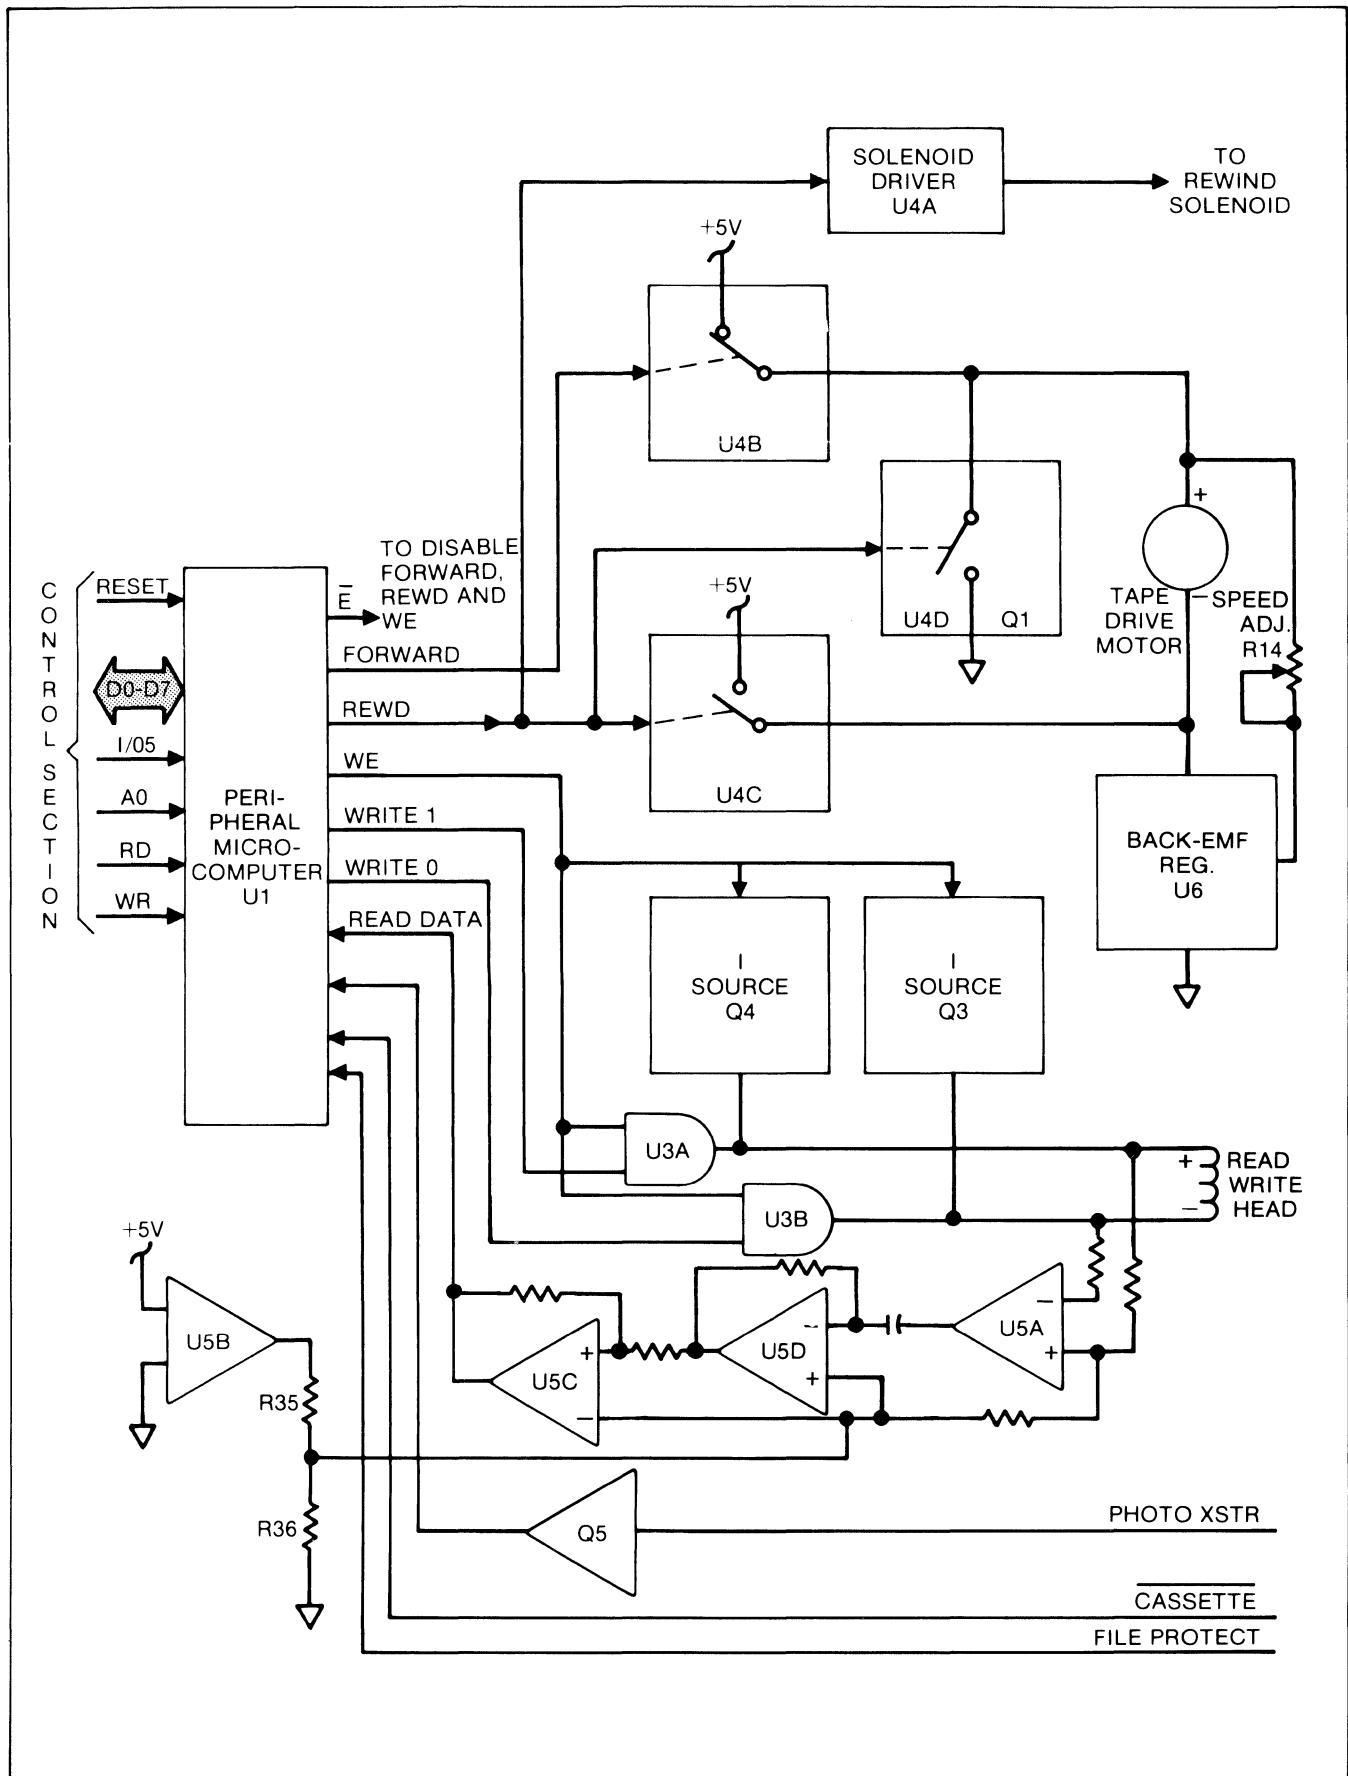

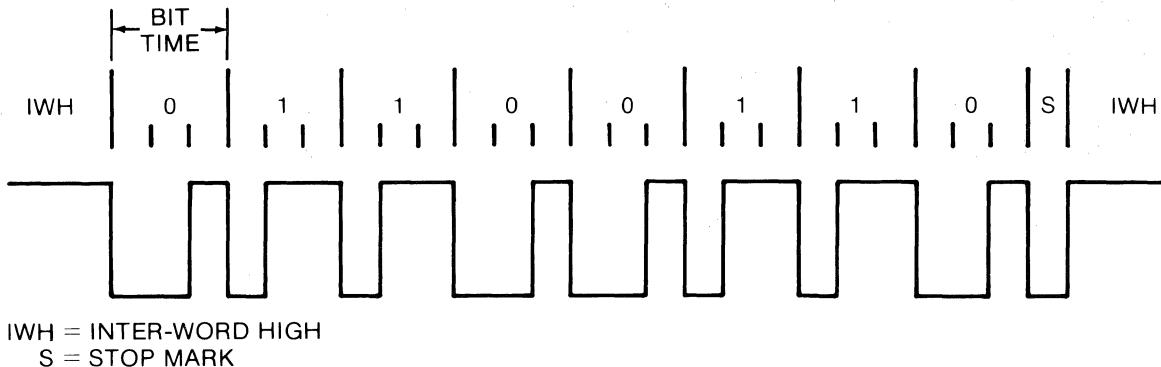

Figure 3-10. Magnetic Tape Controller

**Figure 3-11. Tape Data Ratio Coding**

are applied to the input of the playback amplifier made up of U5A, U5B, U5C, and U5D (shown in Figure 3-10). The purpose of U5B is to establish a reference voltage which is halfway between the upper and lower output limits of the other three stages. Since the output characteristics of U5B are similar to the other three stages, and R35 and R36 are equal, applying +5 volts across the input of U5B produces a level equal to half its saturated output across R36.

3-110. Section U5A of the amplifier provides a gain of 200 and forms the first stage of the playback amplifier. The output of U5A is applied to differentiator stage U5D. CR8 and CR9 are provided to prevent this stage from going into saturation. The final stage is a center-crossing detector with a 25% (approx.  $\pm 0.4V$ ) hysteresis. The three stages combined are used to detect the points of flux reversal on the tape. The output of the playback amplifier connects via the Read Data line to an input of the peripheral microcomputer. The peripheral

microcomputer continuously reads this input during a read operation and decodes the incoming data into logic highs and logic lows.

### 3-111. OTHER FUNCTIONS

3-112. The Magnetic Tape Controller includes three other functions required for proper tape handling, each of which is reported to the peripheral microcomputer. An LED and phototransistor mounted on the tape path provide an indication of end-of-tape when the clear section of tape allows the passage of LED output to reach the phototransistor. Transistor Q5 amplifies the phototransistor output for application to the peripheral microcomputer. In addition, a low Cassette signal indicates the presence of a cassette in the tape drive to the peripheral microcomputer; and a high File Protect signal indicates a write protected (the tab broken out) cassette. Both the File Protect and Cassette signals are produced by microswitches.

## Section 4

# Maintenance

### **4-1. INTRODUCTION**

4-2. This section of the manual contains routine maintenance and troubleshooting information for the 9010A. A list of recommended test equipment is given in Section 1, Table 1-1.

### **4-3. GENERAL INFORMATION**

#### *NOTE*

*The 9010A is double-insulated from the power line. Although the rear panel is connected to earth (green wire), internal signal ground or logic common is floating. Consequently, ground connections for external test equipment must be made to logic common (TP2) on the main assembly.*

### **4-4. Access Information**

4-5. To gain access to all the printed circuit assemblies (pca's) of the troubleshooter, proceed as follows:

1. Invert the instrument on a clean surface and remove the seven retaining screws from the bottom side.
2. Carefully return the instrument to the upright position while holding the top cover in place. Once in the upright position, remove the top cover and lay it to the right side of the instrument.
3. The top cover assembly includes the tape deck and the Magnetic Tape PCA. The display/keyboard is held in place by the top cover.

### **4-6. Cleaning**

#### **CAUTION**

**Do not use aromatic hydrocarbons or chlorinated solvents for cleaning. These solutions will react with the plastic materials used in the instrument.**

4-7. Clean the front panel, the display lens, and the case with a mild solution of detergent and water. Clean dust from the circuit board with low pressure (<20 psi) dry air. Contaminates can be removed from the circuit boards with demineralized water and a soft brush. Dry with clean dry air at low pressure, and then bake at 50 to 60 degrees C (124-140 degrees F) for 24 hours.

4-8. Cleaning of the magnetic tape drive is limited to occasional cleaning of the read/write head. The need for head cleaning is evidenced by the presence of iron oxide. Clean the head with cotton swabs moistened with isopropyl alcohol. Continue to clean the head until the swabs cease to be discolored.

### **4-9. Line Voltage Switch Settings**

4-10. The 9010A can be set to operate from any of four different line voltages: 100V ac, 120V ac, 220V ac, or 240V ac. Two slide switches mounted near the left-front corner of the main assembly can be positioned to configure the 9010A to operate from any of the four input voltages. Refer to Figure 4-1. To select a specific input configuration, insert a flat-tipped screwdriver in switch slots and slide the switches to the required position as shown in Figure 4-1.

### **4-11. FUSE REPLACEMENT**

#### **4-12. Line Fuse**

4-13. The line fuse (F1) is located on the rear panel. Figure 4-2 illustrates line fuse location. Replace the fuse with a 1 ampere slow-blow, 250V (part no. 109272) for 100 and 120 volt operation; replace with a ½ ampere slow-blow, 250V (part no. 109322) for 220 and 240 operation.

#### **4-14. Probe Fuse**

4-15. The troubleshooter detects a probe fuse failure by halting operation and displaying the message REPLACE PROBE FUSE/UNPLUG PROBE. (Typically, the probe fuse is blown by inadvertently connecting the probe

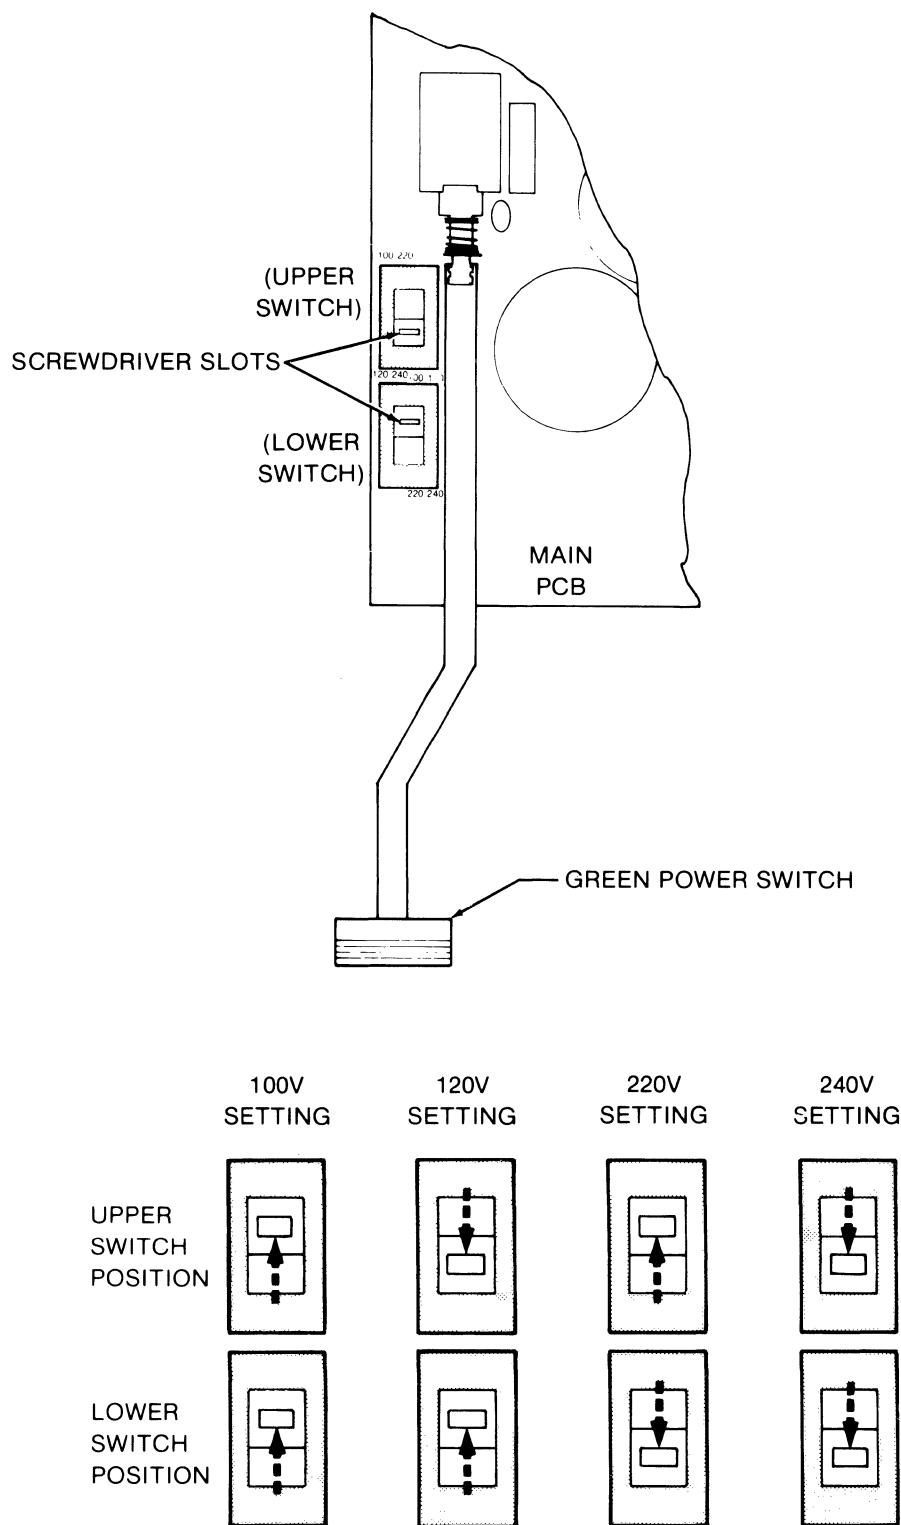

Figure 4-1. Location of Line Voltage Switches and Switch Settings

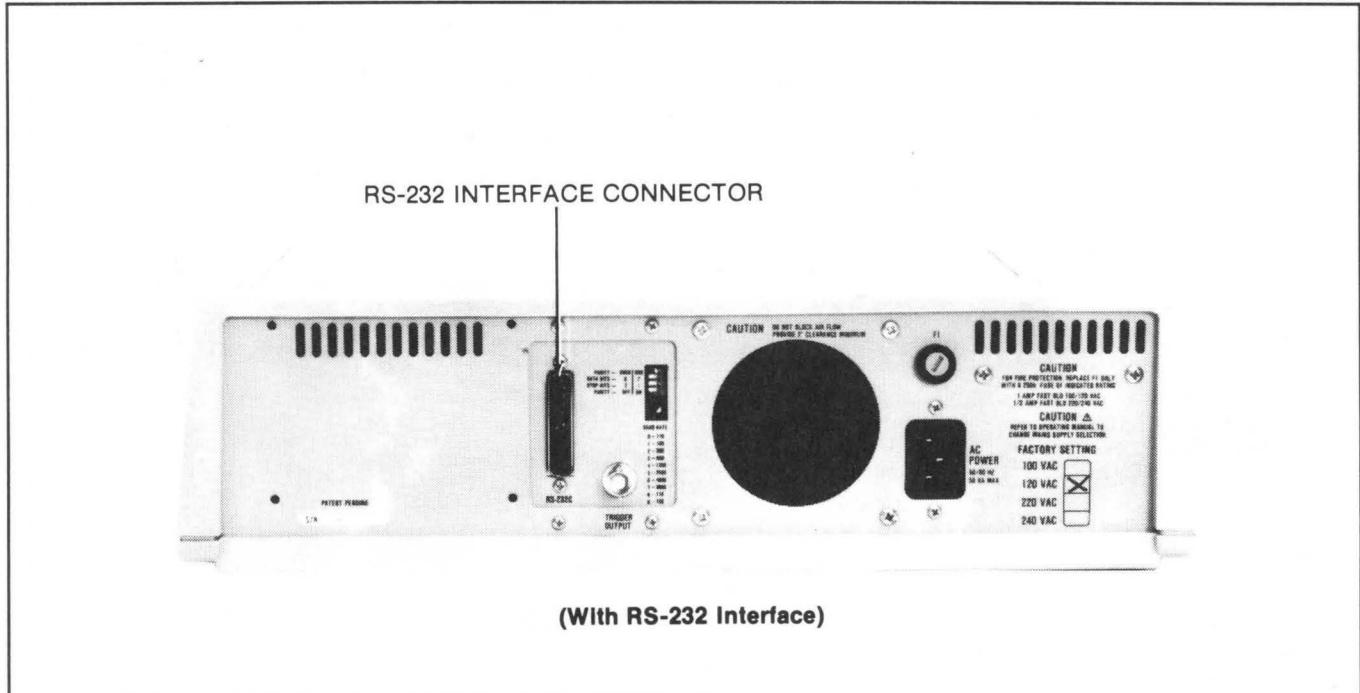

Figure 4-2. 9010A Rear Panel

ground clip to a power source.) To replace the probe fuse, proceed as follows:

1. Tilt up the front of the instrument and locate the probe fuse cap shown in Figure 4-3.
2. Remove the fuse cap by turning 1/8 turn counterclockwise with a screwdriver. Pull out the fuse with the fuse cap. Note the color of the fuse cap.
3. Replace the fuse with one having a 1/4 ampere, 250V rating. For black fuse caps use Fluke part number 543504 (5x20 mm), for grey fuse caps use Fluke part number 109314 (3AG).

#### *NOTE*

*If a spare fuse is not immediately available, remove the probe from the troubleshooter to continue operation without the probe.*

#### **4-16. PERFORMANCE TEST**

##### **4-17. Self Test**

4-18. Upon application of power, the troubleshooter performs a self test to verify proper operation of internal ROM and RAM. Upon successful completion of self test, the troubleshooter displays the message FLUKE 9000 POWER-UP OK VER-nn, where nn represents a number corresponding to the software version contained in the instrument.

4-19. If the self test routine detects a ROM or RAM problem, the troubleshooter displays the message FLUKE 9000 POWER-UP FAIL mm, where mm equals a two-digit hexadecimal failure code. Table 4-1 lists the failure codes and their meanings.

4-20. Troubleshooter self test may also occur at times other than power-on; referred to as restart. The troubleshooter contains a watchdog timer circuit which initiates self test whenever internal operation does not appear normal. In this case, the troubleshooter displays the message FLUKE 9000 RESTARTED SELF TEST followed by either FLUKE 9000 RESTARTED OK VER-nn (where nn equals the software version) or FLUKE 9000 RESTARTED FAIL mm (where mm equals a failure code listed in Table 4-1).

##### **4-21. Probe Level Detection/Verification**

4-22. Check for proper probe detection threshold levels as follows:

1. Connect the probe of the 9010A across the output of a variable dc power supply and the input of a 3-1/2 digit multimeter so that the probe tip connects to the positive terminals and the ground lead connects to the negative terminals. Select an output of zero volts on the power supply.
2. Select free-run synchronization by pressing SYNC followed by F.

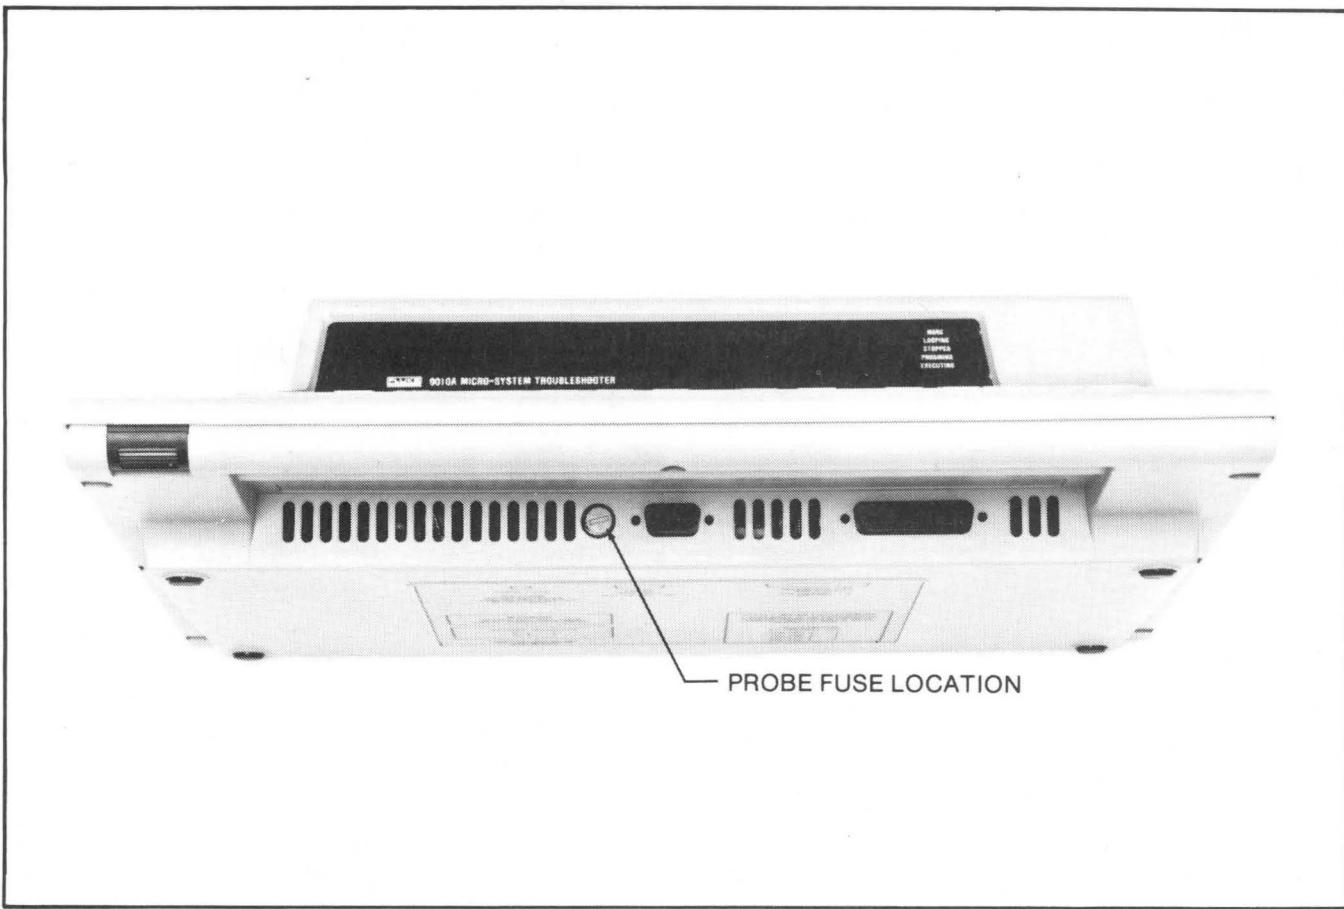

Figure 4-3. Probe Fuse Location

Table 4-1. Self Test Failure Codes

CODE	INDICATED FAILURE
02	RAM failed write FF during power-on
03	RAM failed write FF during restart
04	RAM failed write 00 during power-on
05	RAM failed write 00 during restart
06	RAM failed write FF/00 during power-on
07	RAM failed write FF/00 during restart
08	ROM check failed during power-on
09	ROM check failed during restart
0A	RAM failed write FF and ROM check during power-on
0B	RAM failed write FF and ROM check during restart
0C	RAM failed write 00 and ROM check during power-on
0D	RAM failed write 00 and ROM check during restart
0E	RAM failed write FF/00 and ROM check during power-on
0F	RAM failed write FF/00 and ROM check during restart

3. Increase the power supply output from zero until the green probe lamp just starts flashing. The level on the multimeter should be  $0.8 \pm 0.2$  volts.
4. Continue to adjust the power supply output until the red probe lamp just starts flashing. The multimeter should read  $2.4 \pm 0.2$  volts.
5. If these levels are not met, proceed to the paragraphs titled Checking the Probe Logic.
6. Disconnect probe tip from power supply.

#### **4-23. Probe Pulser Checks**

- 4-24. Check for proper pulser operation as follows:
  1. Set free-run sync by pressing SYNC followed by F.
  2. Select PULSE LOW and verify that the green light on the probe flashes.
  3. Select PULSE HIGH and deselect PULSE LOW; verify that the red light on the probe flashes.
  4. Select both HIGH and LOW and verify that both lights flash.

#### **4-25. Magnetic Tape Check**

- 4-26. Check for proper magnetic tape operation as follows:

1. Install a blank tape (not write protected) into the tape drive and close the lid.
2. Press WRITE TAPE and ENTER/YES. The tape drive should rewind, write, rewind, read, and rewind. The 9010A should display WRITE TAPE OK.

#### **4-27. Pod Connector Checks**

- 4-28. Check the pod connector as follows:

1. Connect a known good interface pod to the 9010A and place the UUT connector of the pod into its self-test connector.
2. Press BUS TEST and verify the message xxxx-POD SELF-TEST OK appears (where xxxx indicates the interface pod type).

#### **4-29. Display/Keyboard Check**

- 4-30. Check the display/keyboard assembly as follows:
  1. Key-in the programs listed in Table 4-2 and then execute program 0. Note that the PRGMING and EXECUTING annunciators light.

**Table 4-2. Display Performance Test**

PROGRAM LISTING	COMMENTS
<pre> PROGRAM 0    161 BYTES  DPY-*****+ DPY-+***** STOP DPY-888888888888888888888888888888 DPY-+88888 STOP DPY-..... DPY-+..... STOP DPY-KEY= 0: LABEL 0 REG0 = 40 DPY-+\$0 1: LABEL 1 IF REG0 &gt;= 40 GOTO 1 DPY-KEY=\$0 GOTO 0 </pre>	<pre> display all "8"s display all "." asynchronous input to reg0 from kybd wait if no key pressed display hex value of key </pre>

2. The display should read all "\*"s and the STOPPED annunciator should light.
3. Press CONT and the display reads all 8's. Press CONT and all decimal points are displayed. Press CONT.
4. The display reads KEY=. Press all keys except STOP, LOW or HIGH and verify the hexadecimal value is the same as shown in Figure 4-4. Press STOP to exit program.

#### **4-31. CALIBRATION ADJUSTMENTS**

#### **4-32. Power Supply Adjustment**

4-33. Adjustment (R2), shown in Figure 4-5, is provided for the +5-volt supply and should be adjusted to obtain a level of +5.1 volts  $\pm 10$  mV at TP10. For proper power supply loading, all assemblies should be connected to the Main Assembly.

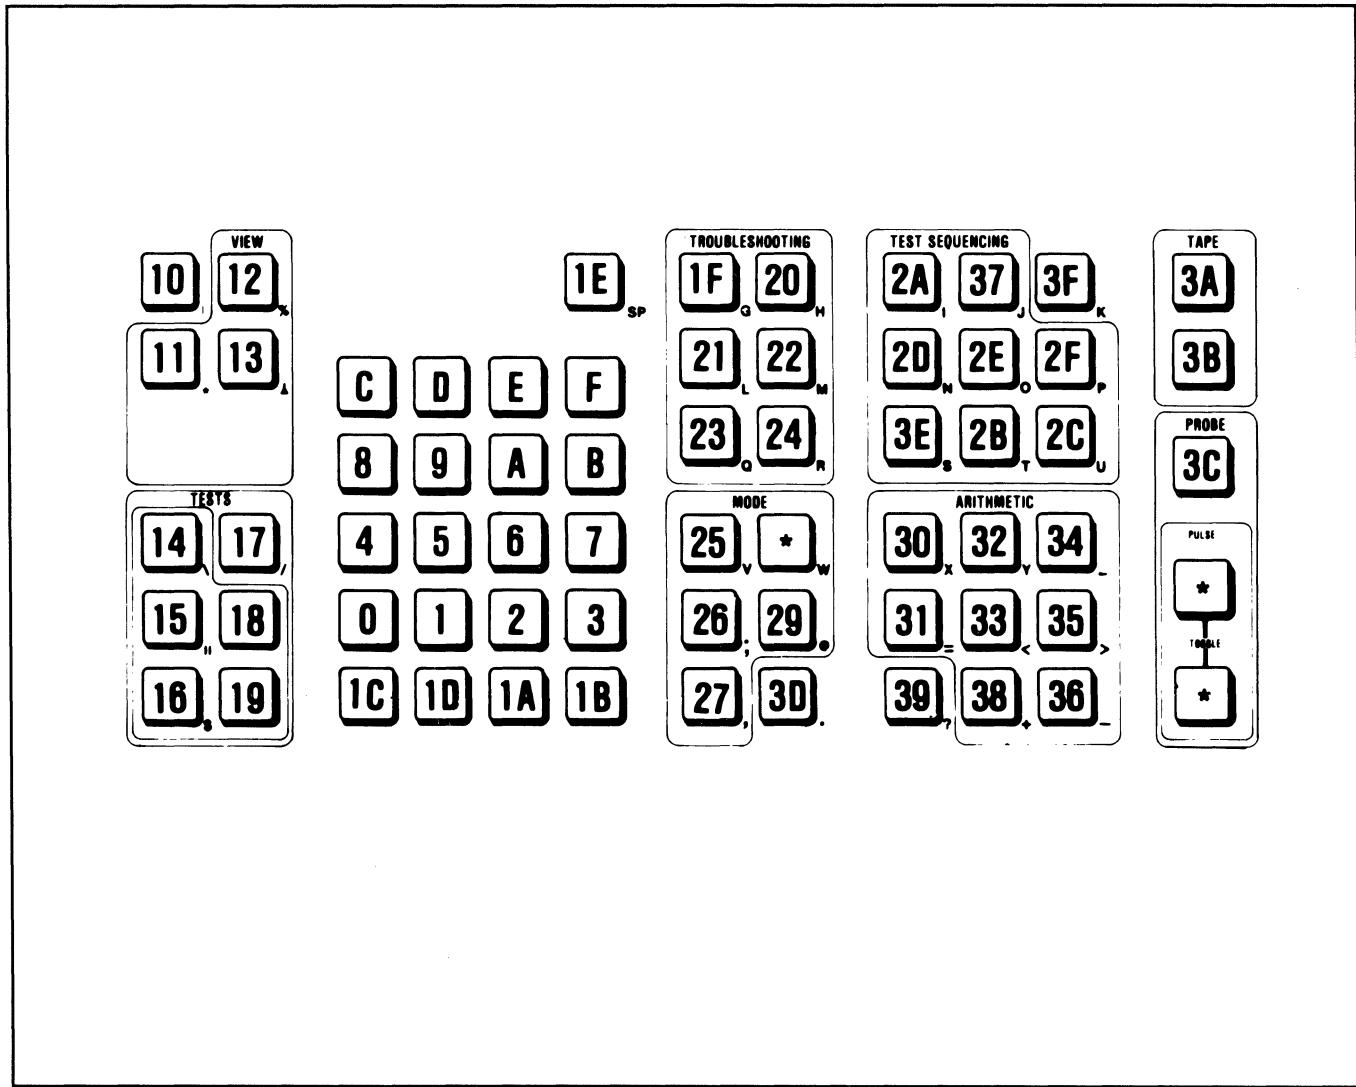

#### **4-34. Magnetic Tape Speed Adjustment**

4-35. Tape speed can be checked and, if necessary, adjusted by means of the following procedure. Gain access to the Magnetic Tape Controller by removing the seven 9010A cover-retaining screws, removing the cover and to expose the Magnetic Tape Controller Assembly.

1. Open the cassette access door of the tape drive and place a strobe disk (part no. 609578 for 60 Hz operation, and part no. 609560 for 50 Hz operation) on the left spindle.

2. Power the 9010A off then on.

3. Select the read test by momentarily jumpering pins 20 and 22 of U1 on the magnetic tape controller assembly.

**Figure 4-4. Asynchronous Input Values**

4. Observe the strobe disk while adjusting R14 (shown in Figure 4-6). The disk strobe lines appear motionless when proper speed is achieved.

#### 4-36. Probe Input Compensation Adjustment

4-37. Adjust as follows:

1. Gain access to the Main Assembly components as described under the heading Access Information.
2. Connect the 9010A probe cable to the underside front connector of the troubleshooter, and leave the probe tip disconnected.
3. Apply power to the troubleshooter.
4. Measure the voltage at TP17(+) with reference to TP1(-). Voltage should be 0,  $\pm 5$  mV. Adjust R64

if necessary. Refer to Figure 4-7 for test point locations.

5. Connect an oscilloscope across TP8 (ground) and TP14 located on the Main Assembly.
6. Adjust the oscilloscope to obtain a display of one or two full cycles of the signal at a vertical sensitivity of 2V/div.
7. Remove the oscilloscope from TP14 and connect to TP1 changing the vertical sensitivity to 100 mV/div.
8. Connect the 9020A probe tip to TP14 and probe GND to TP8.
9. Adjust C52 (shown in Figure 4-7) to obtain best wave, i.e., square corners with minimum over or undershoot.

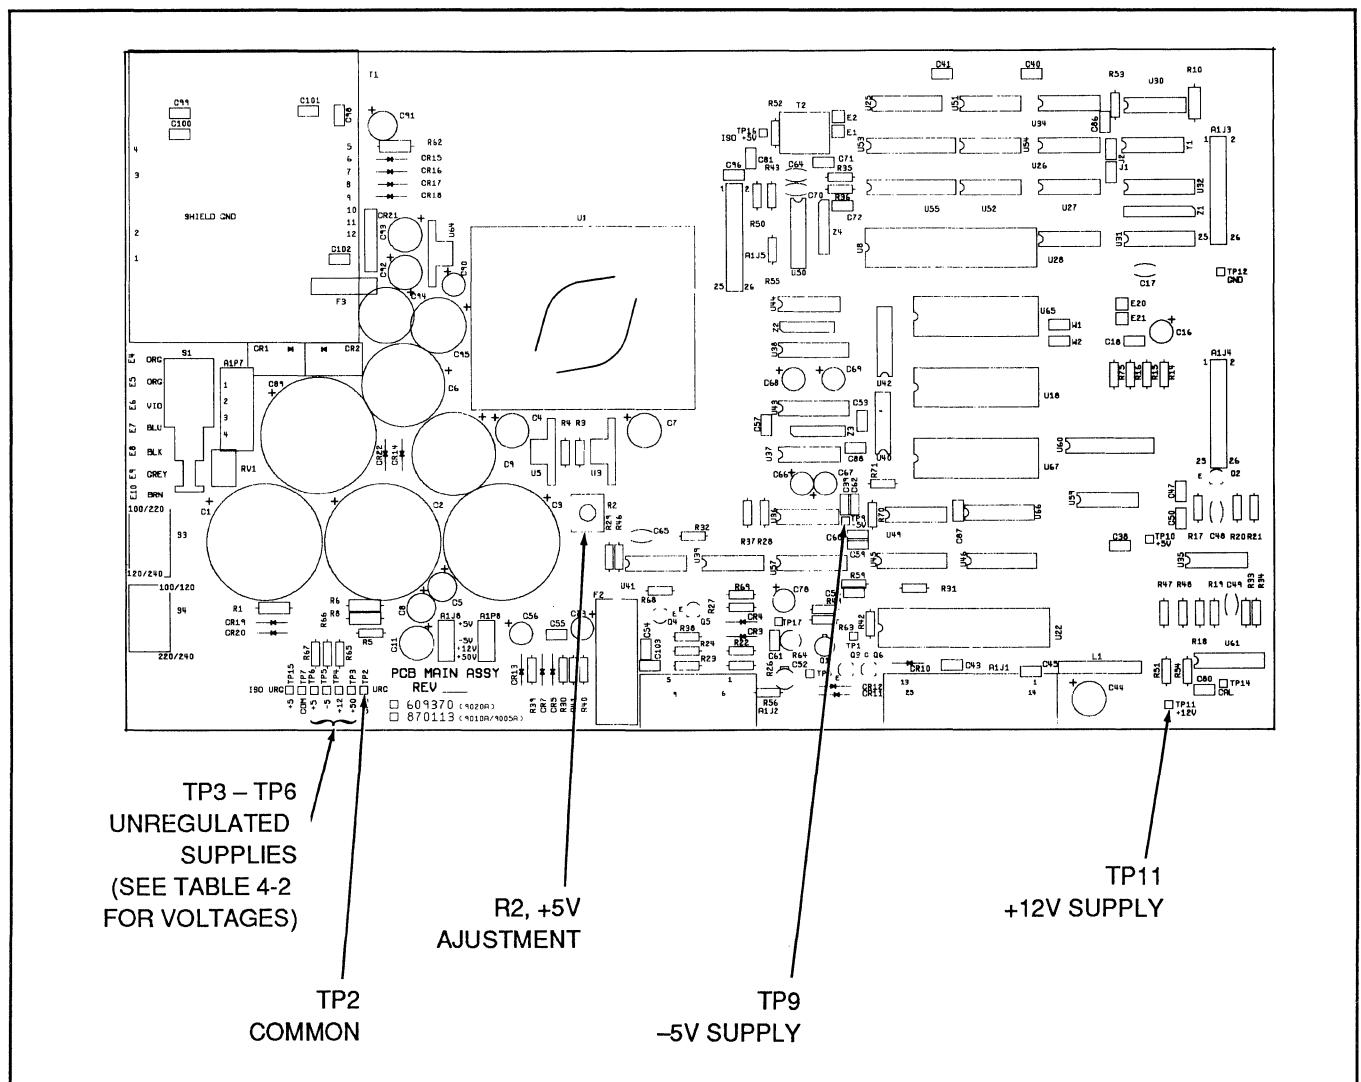

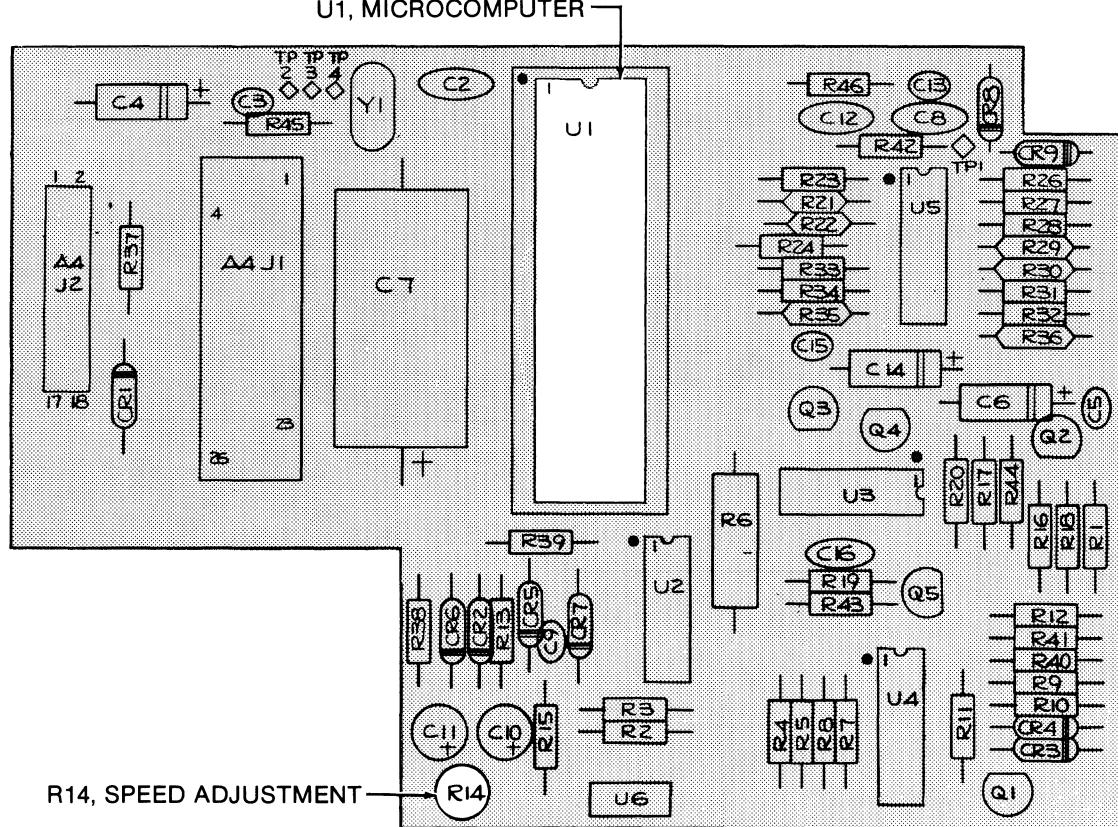

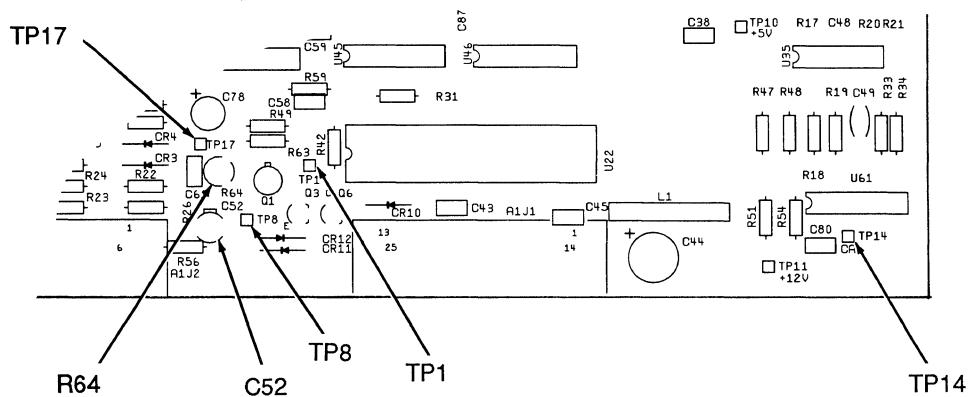

Figure 4-5. Power Supply Test Points and Adjustments

**Figure 4-6. Tape Speed Adjustments**

#### **Figure 4-7. Probe Component Test Points and Adjustments**

6. Adjust C51 and C52 (shown in Figure 4-7) to obtain best wave, i.e., square corners with minimum over or undershoot.

#### 4-38. REPAIR PRECAUTIONS

##### CAUTION

**Static discharge can damage MOS components contained in the troubleshooter. To prevent this possibility,**

- **Do not handle ICs or PCAs by their connectors.**
- **Attach static ground straps to repair personnel.**
- **Use conductive foam to store replacement or removed ICs.**
- **Remove all plastic, vinyl and styrofoam from the work area.**
- **Use a grounded soldering iron.**

##### NOTE

*The soldering iron used for repair should have a rating of 25 watts or less to prevent overheating the PCB assembly.*

#### 4-39. TROUBLESHOOTING

##### 4-40. Introduction

4-41. Troubleshooting the 9010A is similar to troubleshooting any other microprocessor-based unit, and requires the equipment listed in Table 1-1. The troubleshooting information presented in the following paragraphs, plus the fault isolation diagram contained in Section 8 of this manual, provides a troubleshooting guide for use while employing normal fault isolation techniques. In addition, this section contains a series of test programs which can be run using a tester 9010A. These test programs are called out as required in the following troubleshooting procedures.

##### NOTE

*All programs listed in the following sections are included as a starting point for troubleshooting a faulty 9010A. These programs could be expanded as the user becomes more sophisticated in troubleshooting techniques. The programs could also be adapted to the particular style of testing the user desires.*

#### 4-42. Power Supply Checks

4-43. Power supply levels should be checked whenever improper operation of the unit is suspected.

4-44. Using a digital multimeter, check the power supply voltages at the test points listed in Table 4-3 for the listed levels. The location of the power supply test points and adjustment is shown in Figure 4-5. In order to maintain proper power supply loading, do not disconnect the Display/Keyboard Assembly from the Main Assembly. Failure of the unregulated supplies could be caused by a defective transformer (T1), open or shorted rectifier diodes, or open or shorted filter capacitors. Failure of the regulated supplies could be caused by defective regulator devices or shorts at the regulator outputs.

4-45. Ac ripple on all regulated supplies (except the 50-volt supply) is 25 millivolts rms maximum. The 50-volt supply typically contains less than 100 millivolts of ac ripple.

#### 4-46. Bus/RAM/ROM Checks

4-47. Use a second 9010A Troubleshooter, hereafter referred to as the tester 9010A, and a 9000A-Z80 Interface Pod to perform all Main Assembly checks. Gain access to the Z80 socket by removing the seven retaining screws and the top cover from the 9010A. Lift off the top cover assembly and set to the side leaving the two ribbon cables attached. Connect the tester 9010A and the 9000A-Z80 Interface Pod to the main Assembly as follows:

Table 4-3. Power Supply Test Points and Levels

POWER SUPPLY	UNREGULATED (Nominal Line Voltage)		REGULATED	
	TEST POINT	TYPICAL LEVEL	TEST POINT	NORMAL LEVEL V DC
+5V	TP3	+12.8V	TP10	+5.10 to 5.12
-5V	TP5	-14.7V	TP9	-4.75 to 5.25
+8V	TP7	+15.6V	TP13	+7.6 to 8.4
+12V	TP4	+23.1V	TP11	+11.4 to 12.6
+50V	TP6	+55V	—	—

1. With ac power off, remove the Z80 microprocessor (U8) from the A1 Main Assembly.
2. Connect the 9010A-Z80 interface pod to the vacant Z80 socket.
3. With power applied first to the tester 9010A, apply power to the UUT (9010A under repair).
4. Perform a Bus Test. If the test fails, examine the entire tester 9010A display diagnostic to determine the stuck line(s). Isolate any fault using the probe and schematic diagram contained in Section 8.
5. Perform a RAM Short test on address range C000 - FFFF; this test takes about 4 minutes and detects most types of RAM errors. A RAM Long test can also be performed, but allow approximately 67 minutes. RAM addresses are listed in Table 4-4.

*NOTE*

If a RAM failure occurs, carefully examine the diagnostic message. The RAM Test is usually sufficient for deducing the failed component directly.

6. Perform a ROM Test on the entire ROM. ROM addresses and signatures are listed in Table 4-4.

#### 4-48. I/O Selector Checks

4-49. Failure of the I/O selector U25 can result in the failure of any or all I/O devices. The I/O devices within the 9010A include:

- The Signature Generator/Event Counter - Selector outputs 0, 1, 2 and 3
- The Display/Keyboard Assembly - Selector output 4
- The Magnetic Tape Controller - Selector output 5

- The Pod/Probe PIA - Selector output 6
- The RS-232 Interface - Selector output 7

4-50. With the tester 9010A connected to the 9010A under test, hereafter referred to as the UUT, as described for Bus/RAM/ROM Checks, check the individual outputs of the I/O selector as follows:

1. Synchronize the tester 9010A probe to the address sync mode.
2. Perform looping-reads at each I/O selector address listed below, and use the probe to verify low signals at the corresponding outputs. Only one line should be selected low at any given time.

I/O Address	U25 PIN NO.
10000	15
10020	14
10040	13
10060	12
10080	11
100A0	10
100C0	9
100E0	7

#### 4-51. Power-On Reset/Watchdog Timer Checks

4-52. Failure of the power-on reset circuit is indicated by failure of the troubleshooter to execute self test upon the application of ac power. Failure of the watchdog timer may not be obvious since it is normally triggered by some internal malfunction, and such an internal malfunction may not be known to be present. Gain access to the main assembly components as described under the heading Access Information and check these circuits as follows:

1. With the tester 9010A connected to the 9010A under test as described for Bus/RAM/ROM Checks, select the Run UUT mode on the tester 9010A.
2. Using the tester 9010A probe in the sync-free-run pulse-low mode, momentarily connect the

**Table 4-4. Memory Addresses and Signatures**

SOFTWARE VERSION 3.A			
ADDRESSABLE DEVICE	SIGNATURE	ADDRESS (HEX)	COMMENTS
ROM-U65	BF28	0000-BFFF	-1 PROM – JUMPERW2 INSTALLED; JUMPER W1 REMOVED
RAM-U18	N/A	C000-FFFF	

probe tip to U31-4 of the UUT. (Refer to Figure 4-8 for the location of U31.) The UUT should beep and display the power-up message FLUKE9000 POWER-UP OK VER-xx (where xx indicates the current software version number) each time the probe is momentarily connected to U31.

3. Using the tester 9010A probe to read instead of pulse (pulse mode turned off), verify the presence of logic high levels at U31-4 and U31-7, and logic low at U31-6.

4. On the tester 9010A perform a looping-read or -write to address 10080 while observing U31-10 of the UUT with the tester 9010A probe (free-

running). Press STOP on the tester 9010A and verify that the signal at U31-10 goes from high (red) to low (green) after approximately 4 seconds.

#### 4-53. Pod/Probe PIA Checks

4-54. Failure of the pod/probe PIA typically causes communication problems with the pod and/or the probe since all commands and data move through the PIA. Follow the displayed instructions, setting the probe PULSE buttons both out or both in as instructed. Using the following procedure, verify proper operation of the pod/probe PIA. (Figure 4-8 shows the location of the pod/probe PIA U22, U31, U34, and U25.)

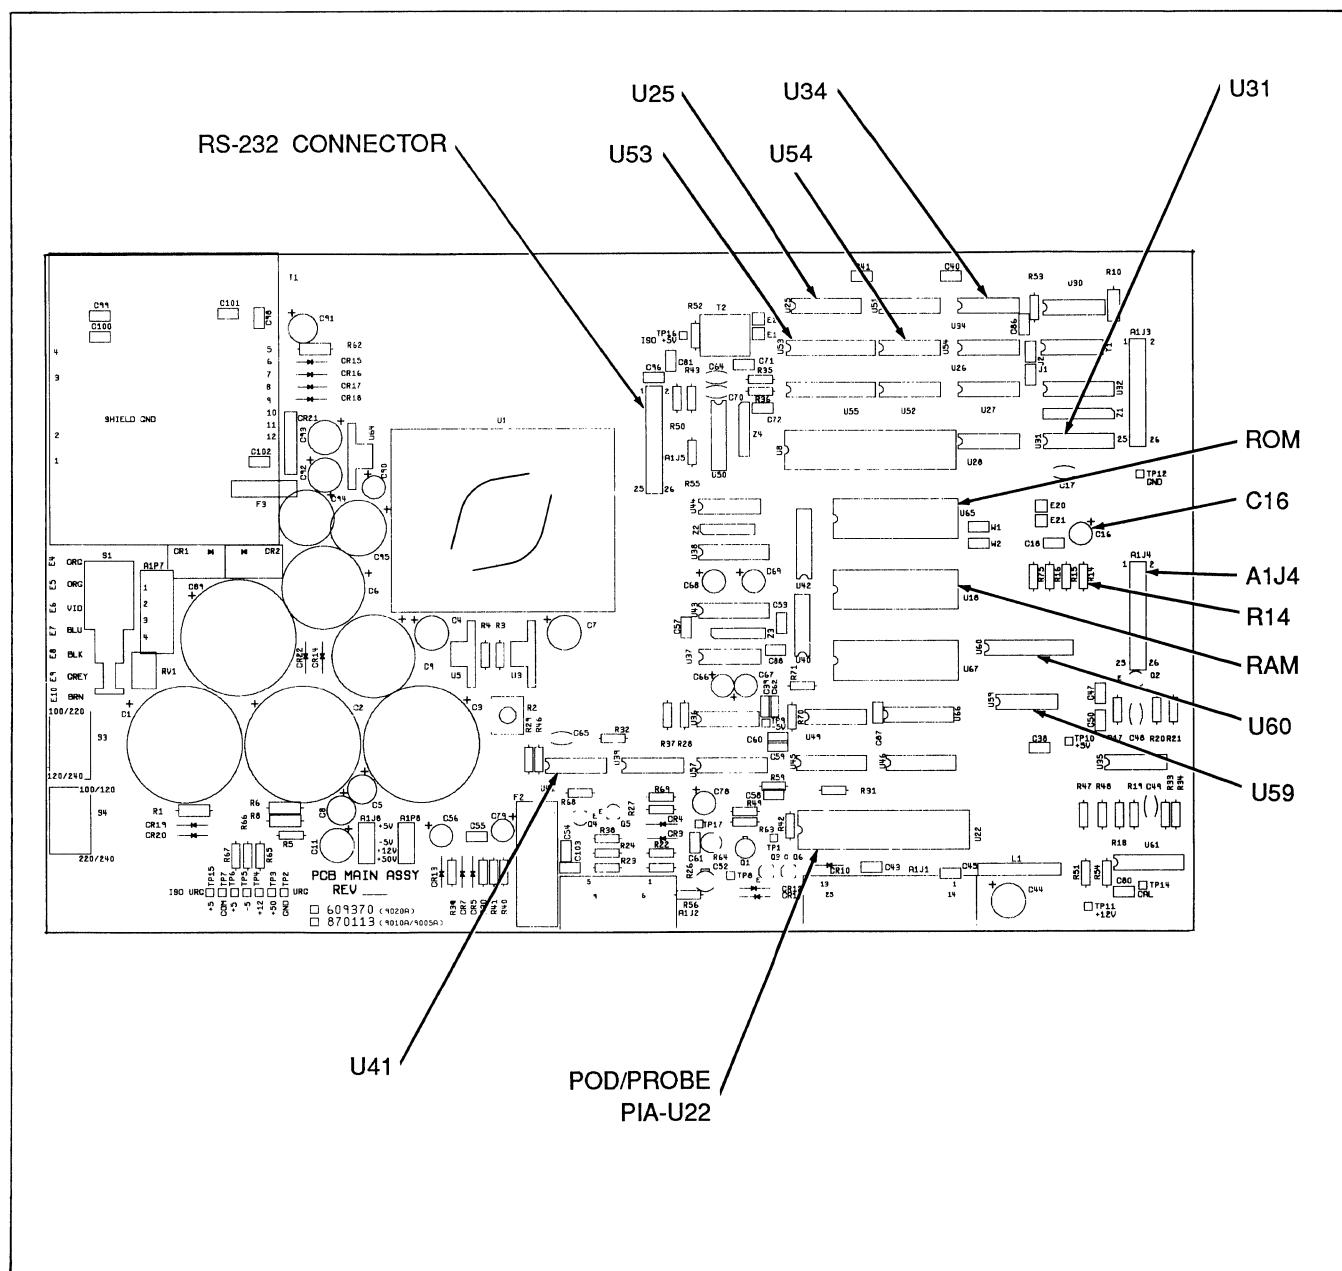

Figure 4-8. Main Assembly Components

1. Turn off the UUT and unplug the Display/Keyboard Assembly from the Main Assembly at A1J4.
2. Disable the watchdog timer U31 by jumpering R14 (the side adjacent to C16) to TP12 (ground). This removes the reset input from the pod/probe PIA and allows it to operate. Turn UUT power on.
3. Check the  $\overline{CS2}$  input of the pod/probe PIA as follows:
  - a. Synchronize the tester probe to the address sync mode.
  - b. Performing a looping-read at address 100C0.
  - c. Check the  $\overline{CS2}$  input at pin 23 of the PIA (U22), using the tester probe and if necessary at pin 10 of U34 and pin 9 of I/O selector U25. Verify that all are logic low.
  - d. Check the  $\overline{EN}$  input at U22 pin 25, CS0 at U22 pin 22, and CS1 at U22 pin 24. Verify that all are logic high.
4. Check the data transfer operation of the PIA (U23) by keying-in programs 11 and 12 listed in Table 4-5 and executing program 11. The program prompts the user for yes/no answers. If a fault occurs, the user has the option to recheck that test or continue with the next test. Any test can be skipped by answering NO in response to the test.

#### **4-55. Probe Related Circuit Checks**

##### **4-56. CHECKING THE PROBE LOGIC**

4-57. The probe logic is divided into four distinct functions:

- Probe Level Detectors
- Free-run Probe Logic
- Synchronized Probe Logic
- Pulse Output

4-58. Checking each function of the probe logic is accomplished by running a short program on the tester 9010A (connected to the faulty 9010A by means of a 9000A-Z80 interface pod and the vacant microprocessor socket as described under the heading Bus/RAM/ROM Checks) in conjunction with some manual checks. It is assumed that the Pod/Probe PIA Checks have been performed and all tests passed.

#### **4-59. Level Detector/Free-Run Checks**

4-60. Perform level detectors/free-run checks as follows:

1. Turn off the UUT and remove the Display/Keyboard Assembly connector A1J4 (shown in Figure 4-8) to disable the beeper. Using a clip lead, disable the watchdog timer (U31) by jumping R14 (the end adjacent to C16) to TP12 (gnd). Turn on the tester 9010A and then the UUT.

2. Verify correct operation of the probe logic in the free-running mode by keying-in programs 2, 12 and 14 listed in Table 4-6 and executing program 2. The program sets up the pod/probe PIA U22 to control the probe logic, and also uses the tester 9010A to verify that the probe logic circuits are operating properly in the UUT.

a. Before running the program, remove the UUT probe and connect to the probe input (at A1J2-2 or at R22) of the UUT to the positive output of a variable dc supply via a 100k, 1%, resistor. (Be sure to install the 100k resistor at the 9010A end of the dc supply test lead in order to prevent noise pick-up.) The negative input should be tied to TP8 (gnd). Also connect the tester probe as directed during program execution.

#### **CAUTION**

**Do not allow the dc supply voltage to exceed 30 volts, or damage to the 9010A may result.**

b. If an incorrect condition occurs, use the probe of the tester 9010A to isolate the fault. The tester display shows the test that failed.

c. Disconnect the dc supply and 100k resistor.

4-61. In general, the signal should be traced through the FET buffer Q1, to HIGH and LOW comparators U36 and U49, through U41 buffers, through flip-flops U37, through selector U38, through one-shot U42, and finally to S/R latches in U46. The reference levels at U36-3 (318 mV) and U49-4 (106 mV) should also be checked using a DVM. If a fault occurs at J2-6 or J2-9, troubleshoot U40, U44, U43 and Q4/Q5.

#### **4-62. Synchronized Probe Check**

4-63. Verify the probe input portion of the probe logic in the synchronized mode by keying-in the programs (3, 12, and 15) listed in Table 4-7 and executing program 3. This program sets up the pod/probe PIA U22 to control U45 and U38. To run the program, perform the following operations.

Table 4-5. PIA (U22) Test

Table 4-6. Free-Running Probe Check (cont)

PROGRAM LISTING	COMMENTS
<pre> PROGRAM 14    102 BYTES  WRITE @ 100C3 = 30 WRITE @ 100C1 = 0 WRITE @ 100C0 = FF WRITE @ 100C1 = 4 WRITE @ 100C0 = 80 WRITE @ 100C3 = 38 WRITE @ 100C1 = 0 WRITE @ 100C0 = 0 WRITE @ 100C1 = 4 READ @ 100C0 REGE = REGE AND E0 </pre>	<pre> cb2=0  pia port a to out  free-run - pulse off cb2=1  pia port a to input  read port a mask off all except level status </pre>

1. Before proceeding make sure the dc supply is disconnected as instructed. Connect the probe tip of a tester 9010A (to be used as a source of sync pulses) to U41, pin 9 of the UUT; connect the ground lead to TP8 (shown in Figure 4-8).

2. Run the program and connect the probe input (A1J2-2 or at R22) of the UUT to logic low (TP8 or TP2); verify the tester display indicates - LOW. Connect the probe to +5V (TP10); verify the tester display indicates - HIGH.

#### 4-64. Probe Pulse Output Check

4-65. Verify the pulse output portion of the probe logic by keying-in programs 4, 12, and 13 listed in Table 4-8 and executing program 4. These programs set up the pod/probe PIA U22 to control U45, which enables U57, U37, U40, and U41. The program, an endless loop, also reads the output from the probe circuit and displays the pulse level on the tester 9010A. While running the program, observe that the lights of the UUT probe correspond to the tester 9010A display messages. Before running the check, remove all connections (except R14 to TP12) made for the previous tests and connect the UUT probe to its connector

#### 4-66. CHECKING THE PROBE FUNCTIONS

4-67. The probe can be checked by substituting with a known good unit from a tester 9010A. If the problem appears to still exist, fault may be in the probe circuitry on the Main Assembly of the 9010A. Proceed to the section titled Checking the Probe Logic to locate the fault. If the probe is determined to be defective, proceed as follows to isolate the fault:

1. Remove the R14 to TP12 jumper connected in previous checks.

2. Press RUN UUT, ENTER/YES on the tester 9010A. Verify the UUT powers up normally.

3. Verify the signal path from the probe tip to the 9010A as follows:

a. Connect the defective UUT probe to the UUT 9010A, and the probe tip to the points listed in the following table (UUT pulse should be off).

b. Using the good probe of the tester 9010A, check the levels at U36-11 and U49-11 located on the main assembly to be as follows. (Ground both probe leads to TP12.)

UUT PROBE INPUT	U36-11 LEVEL	U49-11 LEVEL
5V (TP10)	LOGIC LOW	LOGIC HIGH
GND (TP12)	LOGIC HIGH	LOGIC LOW
OPEN	LOGIC HIGH	LOGIC HIGH

4. Disassemble the probe by unscrewing and withdrawing the rear portion back along the cable. Lift off the probe case half to expose the lamps and printed circuit board assembly.

#### NOTE

*To further disassemble the probe for the purpose of repair, unscrew the ground lead and unsolder the circuit board from the tip.*

5. Verify proper operation of the probe lamps by connecting the UUT probe to the points listed in the following table and observing the lamps. If the lamps do not light in accordance with the table,

check that the lamp(s) are not burned out, and verify their connection to pins 6 and 9 of the probe connector. Also check that +5V appears in pin 4 of the connector located on the UUT.

PROBE INPUT	RED LAMP	GREEN LAMP
+5V (TP10)	ON	OFF
GND (TP12)	OFF	ON
OPEN	OFF	OFF

- To verify operation of the output pulse circuit of the probe, select HIGH and LOW pulses on the UUT and observe the lamps. Both lamps should flash. If the lamps do not flash, connect the UUT probe to the probe of the tester 9010A. If the lamps of the tester 9010A probe do not flash, check the +5 volts supply to the probe; also check drivers Q1 and Q2 within the probe and their connections to pins 3 and 7 of the probe connector. If the lamps of the tester 9010A probe do flash, perform the Probe Level Detection/Verification.

#### 4-68. Signature Register Checks

4-69. A check of the signature register may be made if the UUT displays inconsistent or incorrect signatures for known-good UUTs. Connect the tester 9010A to the UUT as described under the heading Bus/RAM/ROM Checks. To check the signature counter, shown in sheet 4 of the Main Assembly schematic, key-in programs 5 and 12 listed in Table 4-9 and execute program 5. During program execution, follow the instructions on the tester 9010A display; press CONT after each messages.

#### NOTE

*The Signature Register Test program (listed in Table 4-9) uses the tester 9010A probe to generate sync pulses to the UUT signature register. The program also verifies the correct data after shifting a "1" bit through the register.*

#### 4-70. Event Counter Checks

4-71. A check of the event counter circuit should be made if the troubleshooter displays inconsistent or incorrect counts for known-good UUTs. Check the event counter, U59 and U60, shown in sheet 4 of the Main Assembly schematic and in Figure 4-8, as follows:

- Be sure the UUT probe is connected.
- Key-in programs 9 and 12 listed in Table 4-10 and execute program 9.
- Repeat execution of the program by pressing the REPEAT key. If the counter test fails, note the bit in error and replace the appropriate device, U59 or U60.

#### 4-72. Display/Keyboard Checks

4-73. The Display/Keyboard Assemblies contain resident test programs which provide for complete testing of both assemblies. These tests can be performed at any time without the need for a tester 9010A by removing the 9010A Troubleshooter cover and lifting out the Display/Keyboard Assembly. Orient the Display/Keyboard Assembly so that the test points shown in Figure 4-9 are accessible and the display is visible. Apply power to the UUT, jumper R14/C16 to TP2 on the Main Assembly to disable watchdog timer and then perform the following tests as required.

#### 4-74. DISPLAY SEGMENT TEST

4-75. The display segment test causes each segment of each display character to sequentially light. The free-running probe of a tester 9010A can be used to verify segment data to the display via U11, U12, U13 and U14. To initiate the display segment test, momentarily jumper TP5 (ground) to TP0 (located on the Display Assembly); or, if the UUT is connected to a tester 9010A, perform WRITE @ 10081 = 00, followed by WRITE @ 10081 = 01.

#### 4-76. DISPLAY DIGIT DRIVERS TEST

4-77. The digit drivers test creates an all-segment character and walks the character across the entire display. The free-running probe of the tester 9010A can be used to verify digit driver signals at U3, U4, U5, U6, U7, U8, U9, and U10. To initiate the digit drivers test, momentarily jumper TP5 (ground) to TP1 (located on the Display Assembly) or, if the UUT is connected to a tester 9010A, perform WRITE @ 10081 = 00, followed by WRITE @ 10081 = 02.

#### 4-78. DISPLAY ANNUNCIATOR TEST

4-79. The annunciator test causes the MORE, STOPPED, and EXECUTING annunciators to flash when the PULSE HIGH switch is depressed and the LOOPING and PROGMING annunciators to flash when the PULSE LOW switch is depressed. To initiate the annunciator test, momentarily jumper TP5 (ground) to TP2 (located on the Display Assembly) or, if the UUT is connected to a tester 9010A, perform WRITE @ 10081 = 00, followed by WRITE @ 10081 = 04.

#### 4-80. KEYBOARD TEST

4-81. The keyboard test, when initiated, writes the segment pattern shown in Figure 4-10 to the display. Initiate the keyboard test by momentarily jumpering TP5 (ground) to TP3 (located on the Display Assembly) or, if the UUT is connected to a tester 9010A, perform WRITE @ 10081 = 00, followed by WRITE @ 10081 = 08. Note the following:

- As each key (except HIGH and LOW) is pressed, the corresponding portion of the display goes out.

**Figure 4-9. Display Keyboard Self-Test Points**

Pressing all keys results in a blank display. Refer to Figure 4-10 and Table 4-11 for key/switch identification.

- A shorted key causes the corresponding portion of the display to remain blank when initiating the test.
- If two or more keys are shorted, two or more portions of the pattern go out when one of the keys is pressed.
- An open switch causes a portion of the pattern to remain.

#### 4-82. DISPLAY/KEYBOARD RESET

4-83. To reset the Display/Keyboard Assembly, momentarily jumper TP5 (ground) to TP4 (located on the Display Assembly) or, if the UUT is connected to a tester 9010A, perform WRITE @ 10081 = 00, followed by WRITE @ 10081 = 00.

#### 4-84. DISPLAY KEYBOARD COMMUNICATION CHECKS

4-85. Communication between the microprocessor and the display/keyboard peripheral microcomputer may be checked by keying-in programs 6, 12, and 13 listed in Table 4-12 and executing program 6. The program verifies that the main microprocessor is able to communicate with the peripheral microcomputer by attempting to write data to the display and read data from the keyboard. In addition, proper operation of the status registers are verified and also the self-test commands are checked for proper operation.

#### 4-86. Magnetic Tape Controller Checks

4-87. The Magnetic Tape Controller contains resident test programs which provide testing of the controller and tape drive. These tests can be performed at any time without the need for a tester 9010A by removing the troubleshooter cover and inverting it to expose the Magnetic Tape Controller shown in Figure 4-6. Apply power to the troubleshooter and perform any or all of the following tests.

**4-88. SELF TEST**

4-89. Initiate self test by removing and reapplying power to the 9010A and then momentarily jumpering pins 20 (ground) and 21 (SLFTST) of microcomputer U1 on the Magnetic Tape Assembly. (Be sure to use a blank tape, or one that contains old data and is not write-protected.) The self test causes the controller to perform the following functions:

- Rewind the tape
- Write one thousand words of known data
- Rewind the tape
- Read and check the written data
- Stops upon the detection of any read error
- Repeats the entire sequence until reset by jumpering pins 20 and 4 of microcomputer U1

4-90. If the magnetic tape drive stops during the self test, a failure is indicated. Perform the read and write tests in order to isolate the fault. If the magnetic tape drive passes the read and write tests, perform the checks presented under the heading Magnetic Tape Communications Checks.

**4-91. MAGNETIC TAPE READ TEST**

4-92. Initiate the read test by momentarily jumpering pins 20 and 22 (RDTST) of microcomputer U1. The read test causes the controller to perform the following functions:

- Rewind the tape
- Operate the tape drive in the read mode
- If a cassette is installed, rewinds at end-of-tape and repeats the read operation

4-93. During performance of the read test, make the following checks:

1. During the rewind portion of the read test, check for approximately +4.8V (solenoid voltage) at A4J2, pin 14; approximately +0.2V (+ motor voltage) at A4J2, pin 17; and approximately +4.8V (- motor voltage) at A4J2, pin 18. If any voltage is not correct, trace the signal from U1, pin 33, (REWD) through U2 and U4 to locate the fault. Also verify that the solenoid pulls in during rewind.

2. Using an oscilloscope, verify that U1, pin 27 (CLEAR LEADER) is high just as the tape starts forward and is still on clear leader, and then drops low. Also observe a low 20 ms pulse as the start-of-

tape hole passes over the optical sensing path. If these signals do not occur, check Q5; verify that the LED conducts by measuring voltage drop across R38; and check that A4J2, pin 8 (PHOTO XSTR) drops low when on clear leader. If all active devices appear normal, check alignment of the optical path.

3. During forward read, the Motor (+) voltage (A4J2-17) should be at approximately +4.8V dc. If not, check the Forward signal from U1-32 through U2-A and transistor U4B. The Motor(-) (A4J2-18) should measure approx 2.5V dc. If not check U6 and its related components.

4. Using a tape with data already recorded and a storage type oscilloscope, verify the waveforms at U5A-1, U5D-14, U5C-8 and U5B-7 against those shown in Figure 4-11. Be sure to note the voltage levels. Be sure the Head(+) (A4J2-3) and Head(-) (A4J2-4) wires are connected. If the proper signals are not present, a faulty U5 or an open resistor is indicated. Be sure to check that the signal at U5B-8 is also present at U1-39.

5. Verify that U1-27 is logic low with a cassette installed and logic high when the tape lid is open.

6. Verify that U1-38 is logic low with a cassette installed that has the file protect tab not removed, and logic high if the tab is removed.

**4-94. MAGNETIC TAPE WRITE TEST**

4-95. Initiate the write test by momentarily jumpering pins 20 (ground) and 23 (WTTST) of microcomputer U1. The write test causes the controller to perform the following functions:

- Rewind the tape.
- Operate the tape drive in the forward direction and write the hexadecimal word CA at all locations on the tape.
- Rewinds at end-of-tape and repeats the write operation.

4-96. During performance of the write test, verify that the Head+ signal at A4J2-3 and the Head- signal at A4J2-4 appear as shown in Figure 4-12. If the signals are not as shown, check gates U3-A, B, and D; transistors Q2, Q3, and Q4; and associated resistors.

**NOTE**

*If the read and write test fail to isolate and correct a fault that causes failure of self test, it is possible that the controller passes self test but does not communicate properly with the main microprocessor.*

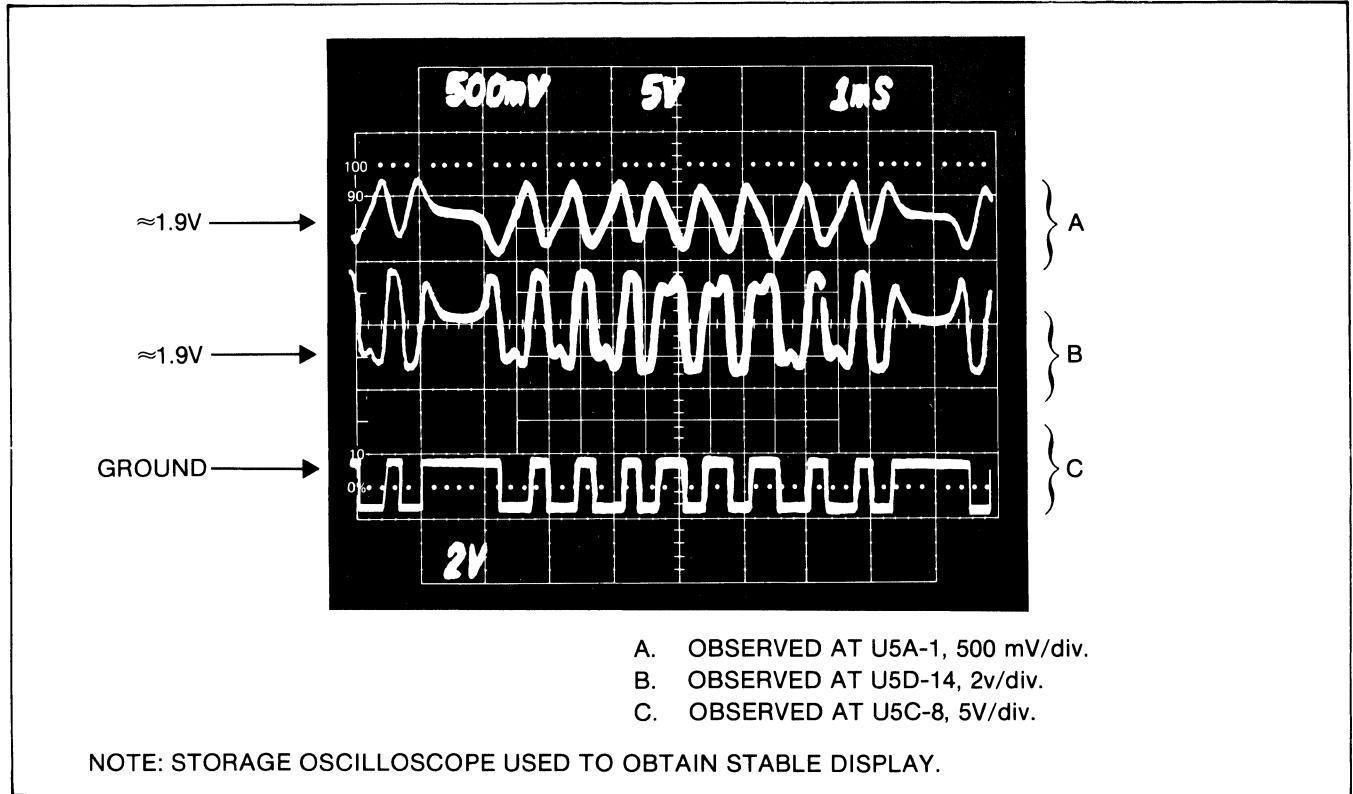

Figure 4-11. Read Test Waveforms

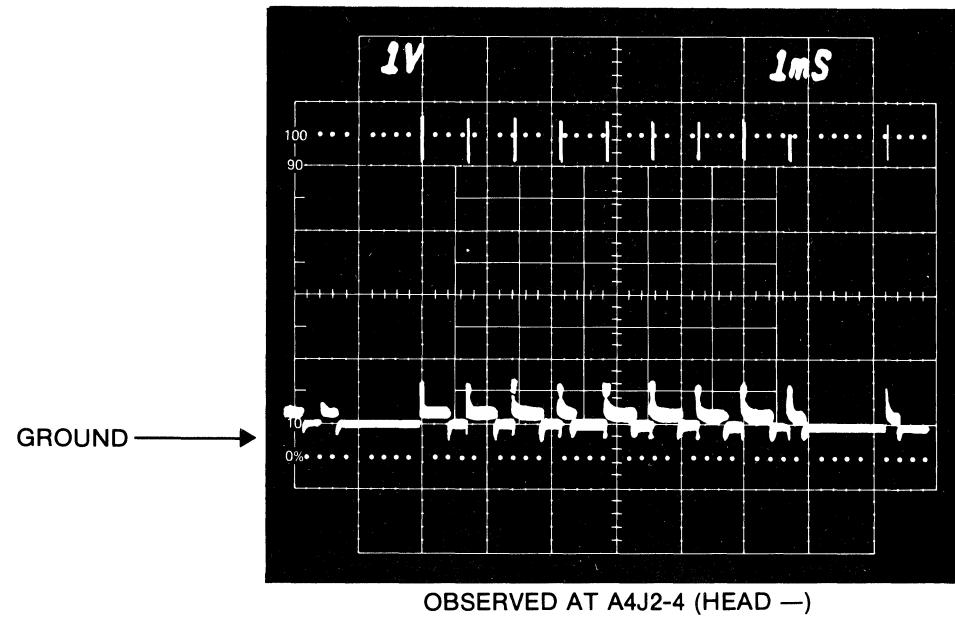

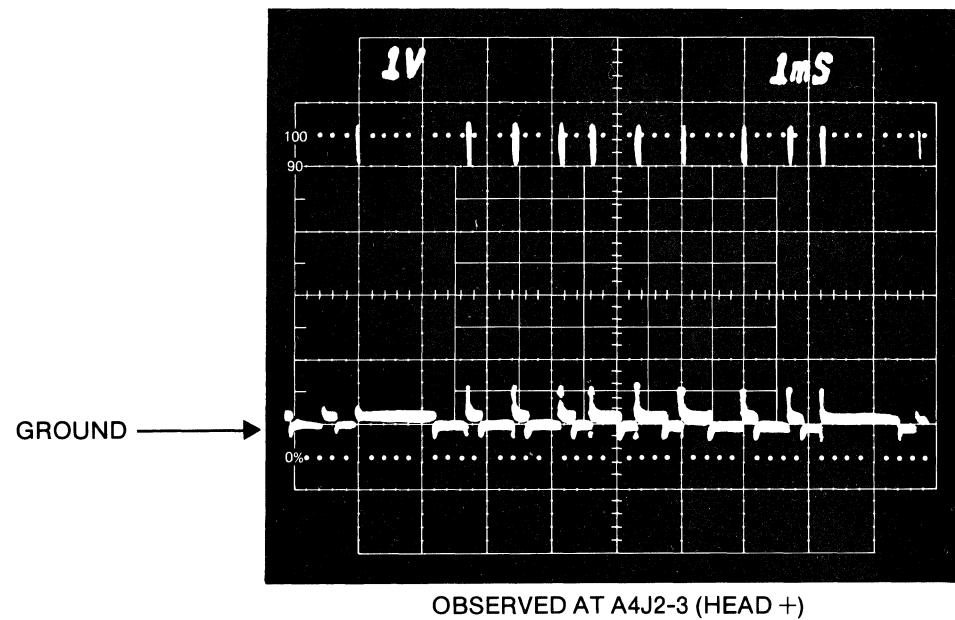

## 4-97. MAGNETIC TAPE COMMUNICATION CHECKS

4-98. Communications between the microprocessor, via the address and data bus, can be checked by means of a tester 9010A connected as described for Bus/RAM/ROM Checks. Using the tester 9010A, check communication by performing the following operations:

1. Disable the watchdog timer U31 by jumpering the C16 side of or R14 (located on the main assembly) to TP12 (ground).
2. Remove any tape cassette and leave the door open.
3. Turn UUT power off then on. Perform a looping read at location 100A1. The data read should be 14. Reach inside the tape deck cover press the cassette-present switch located at the right of the head at the rear of the unit. The data read should be 10. Press the write protect switch located at the front of the unit and verify data read is 04.
4. Install a blank cassette (or one with obsolete data), which is not write protected, into the tape drive with the full reel to the left. Write a 11 to location 100A1. This write causes the tape to rewind and then move forward stop, rewind, go forward slightly and stop.
5. Read at location 100A1 and verify data is 48.

6. If these tests fail, perform the following series of manual tests:

- a. With the tester 9010A probe in the free-run mode, verify that U1-4, 5, 26, and 40 are at logic high; U1-7 and 20 are at logic low; and that U1-2 alternates between high and low.
- b. With the tester 9010A probe synchronized to address, verify that U1-8 ( $\overline{RD}$ ) goes low when a read at location 100A0 is performed.
- c. With the tester 9010A probe in the free-run mode, verify that U1-10 ( $\overline{WR}$ ) goes low as a write at location 100A0 is repeated.
- d. With the tester 9010A probe synchronized to address, verify that U1-9 (A0) toggles when a toggle address at location 100A0, bit 0 is performed.
- e. With the tester 9010A probe synchronized to address, verify that U1-12 (D0) toggles as a toggle data at location 100A0, bit 0 is repeated. Repeat at pins 13 through 19 for bits 1 through 7 of location 100A0.
- f. If the above tests do not locate a faulty line of the microcomputer, replace U1 with a known-good device and recheck operation of the controller.

NOTE: STORAGE OSCILLOSCOPE USED TO OBTAIN STABLE DISPLAY.

Figure 4-12. Write Test Waveform

**Table 4-13. Memory and I/O Device Addressing and Commands**

MEMORY PAGE ADDRESSES			
MEMORY PAGE	ADDRESS	TYPE	REFERENCE DESIGNATOR
0	0000 - BFFF	ROM	U65
1	C000 - FFFF	RAM	U18
DISPLAY/KEYBOARD ASSEMBLY PROTOCOL			
ADDRESS	DATA	WRITE/READ	FUNCTION PERFORMED
10080	Any	Both	Used to write and read data between the main microprocessor and the display peripheral microcomputer. On a write, sends data to the current display character. On a read, gates keyboard data. (After a write, the position pointer is incremented by one to enable the next digit to the right on the display.)
10081	FF(hex)	Write	Master reset
10081	C0(hex)	Write	Clears the 32-character display.
10081	80(hex)	Write	Turns off flashing character mode.
10081	110xxxxx (binary)	Write	Turns off the display for xxxx scans of the display, where xxxx is the binary number of display scans; e.g. 00001 = one scan, 1000 = 16 scans, 11111 = 31 scans.
10081	011bbbb (binary)	Write	Sets flashing character in the display position represented by bbbbb, where bbbbb is a binary number; 00000 = leftmost position, 11111 = rightmost position.
10081	010bbbb (binary)	Write	Turns on annunciator LEDs as follows: bbbb 00001 = EXECUTING 00010 = PROGRAMMING 00100 = STOPPED 01000 = LOOPING 10000 = MORE
10081	001bbbb (binary)	Write	Moves the store pointer to the display position represented by bbbbb, where bbbbb is a binary number; 00000 = leftmost position, 11111 = rightmost position (usually followed by a write at address 10080 to place data in the selected display position).
10081	01(hex)	Write	Selects display segment (self) test.
10081	01(hex)	Write	Selects digit drivers (self) test.
10081	04(hex)	Write	Selects annunciator (self) test.
10081	08(hex)	Write	Selects keyboard (self) test.
10081	00(hex)	Write	Selects reset test mode (always precedes the above self tests).
10081	bbbbbbb (binary)	Read	Causes peripheral microcomputer to respond with a bbbbbbb status byte as follows: bbbbbbb xxxxxx1 = Output buffer and display full xxxxxx1x = Input buffer from keyboard full xxxx1xxx = Last write was control xxxx0xxx = Last write was data 1xxxxxx = Overrun error (more than one key pressed before data read)

**Table 4-13. Memory and I/O Device Addressing and Commands (cont)**

<b>POD/PROBE PIA (U22) INTERNAL REGISTER/BUFFER ADDRESSES</b>			
<b>ADDRESS</b>	<b>WRITE DATA</b>	<b>REGISTER/BUFFER ADDRESSED AND FUNCTION</b>	
100C1	00	Sets I/O Port A control register to allow addressing of I/O Port A data direction register.	
100C1	04	Sets I/O Port A control register to allow addressing of I/O Port A data buffer.	
100C0	As Required	Sets the I/O Port A data direction register in accordance with the write data, or addresses the I/O Port A data buffer; depending upon the previous setting of the I/O Port A control register.	
100C3	00	Sets I/O Port B control register to allow addressing of I/O port B data direction register.	
100C3	04	Sets I/O Port B control register to allow addressing of I/O Port B data buffer.	
100C2	As Required	Sets the I/O Port A data direction register in accordance with the write data, or addresses the I/O Port A data buffer; depending upon the previous setting of the I/O Port A control register.	
<b>POD/PROBE PIA (U22) PROTOCOL</b>			
<b>ADDRESS</b>	<b>DATA</b>	<b>WRITE/READ</b>	<b>FUNCTION PERFORMED</b>
100C1	00(hex)	Write	Refer to above table of addresses.
100C1	04(hex)	Write	Refer to above table of addresses.
100C3	00(hex)	Write	Refer to above table of addresses.
100C3	04(hex)	Write	Refer to above table of addresses.
100C0	FF(hex)	Write	Sets I/O port A data direction register so that all I/O port A data buffer lines are outputs (follows a WRITE @ 100C1 = 00).
100C0	00(hex)	Write	Sets I/O port A data direction register so that all I/O port A data buffer lines are inputs (follows a WRITE @ 100C1 = 00).
100C2	FF(hex)	Write	Sets I/O port B data direction register so that all I/O port B data buffer lines are outputs (follows a WRITE @ 100C3 = 00).
100C2	00(hex)	Write	Sets I/O port B data direction register so that all I/O port B data buffer lines are inputs (follows a WRITE @ 100C3 = 00).
100C3	30(hex)	Write	Sets PIA output CB2 to off.
100C3	38(hex)	Write	Sets PIA output CB2 to on.

**5-1. INTRODUCTION**

5-2. This section contains an illustrated parts breakdown of the instrument. A similar parts list is included in the Options and Accessories Section for each of the options. Components are listed alphanumerically by assembly. Both electrical and mechanical components are listed by reference designation. Each listed part is shown in an accompanying illustration.

5-3. Parts lists include the following information:

1. Reference Designation.
2. Description of Each Part.
3. FLUKE Stock Number.
4. Federal Supply Code for Manufacturers.
5. Manufacturer's Part Number.
6. Total Quantity of Components Per Assembly.

**5-4. HOW TO OBTAIN PARTS**

5-5. Components may be ordered directly from the manufacturer's part number, or from the John Fluke Mfg. Co., Inc. or an authorized representative by using the FLUKE STOCK NUMBER. In the event the part ordered has been replaced by a new or improved part, the replacement will be accompanied by an explanatory note and installation instructions if necessary.

5-6. To ensure prompt and efficient handling of your order, include the following information.

1. Quantity.

**2. FLUKE Stock Number.****3. Description.****4. Reference Designation.****5. Printed Circuit Assembly Part Number and Revision Letter.****6. Instrument Model and Serial Number.**

5-7. Parts price information is available from the John Fluke Mfg. Co., Inc. or its representative. Prices are also available in a Fluke Replacement Parts Catalog, which is available upon request.

**5-8. MANUAL STATUS INFORMATION**

5-9. Table 5-7 defines the revision levels of the pca's documented in this manual. To identify the configuration of the pca's used in your instrument, refer to the revision letter (marked in ink) on the component side of each pca.

**5-10. NEWER INSTRUMENTS**

5-11. As changes and improvements are made to the instrument, they are identified by incrementing the revision letter marked on the affected pca. These changes are documented on a supplemental change/errata sheet which, when applicable, is inserted at the front of the manual.

**CAUTION**

\*

**Indicated devices are subject to damage by static discharge.**

Table 5-1. 9010A Final Assembly

An \* in 'S' column indicates a static-sensitive part.

NOTE 1 = MP30 includes: 1 clip hook 602938, 1 alligator clip 602946, 1 ground lead 609115, 1 IC tip 583674.

NOTE 2 = Used on 230V configuration units only.

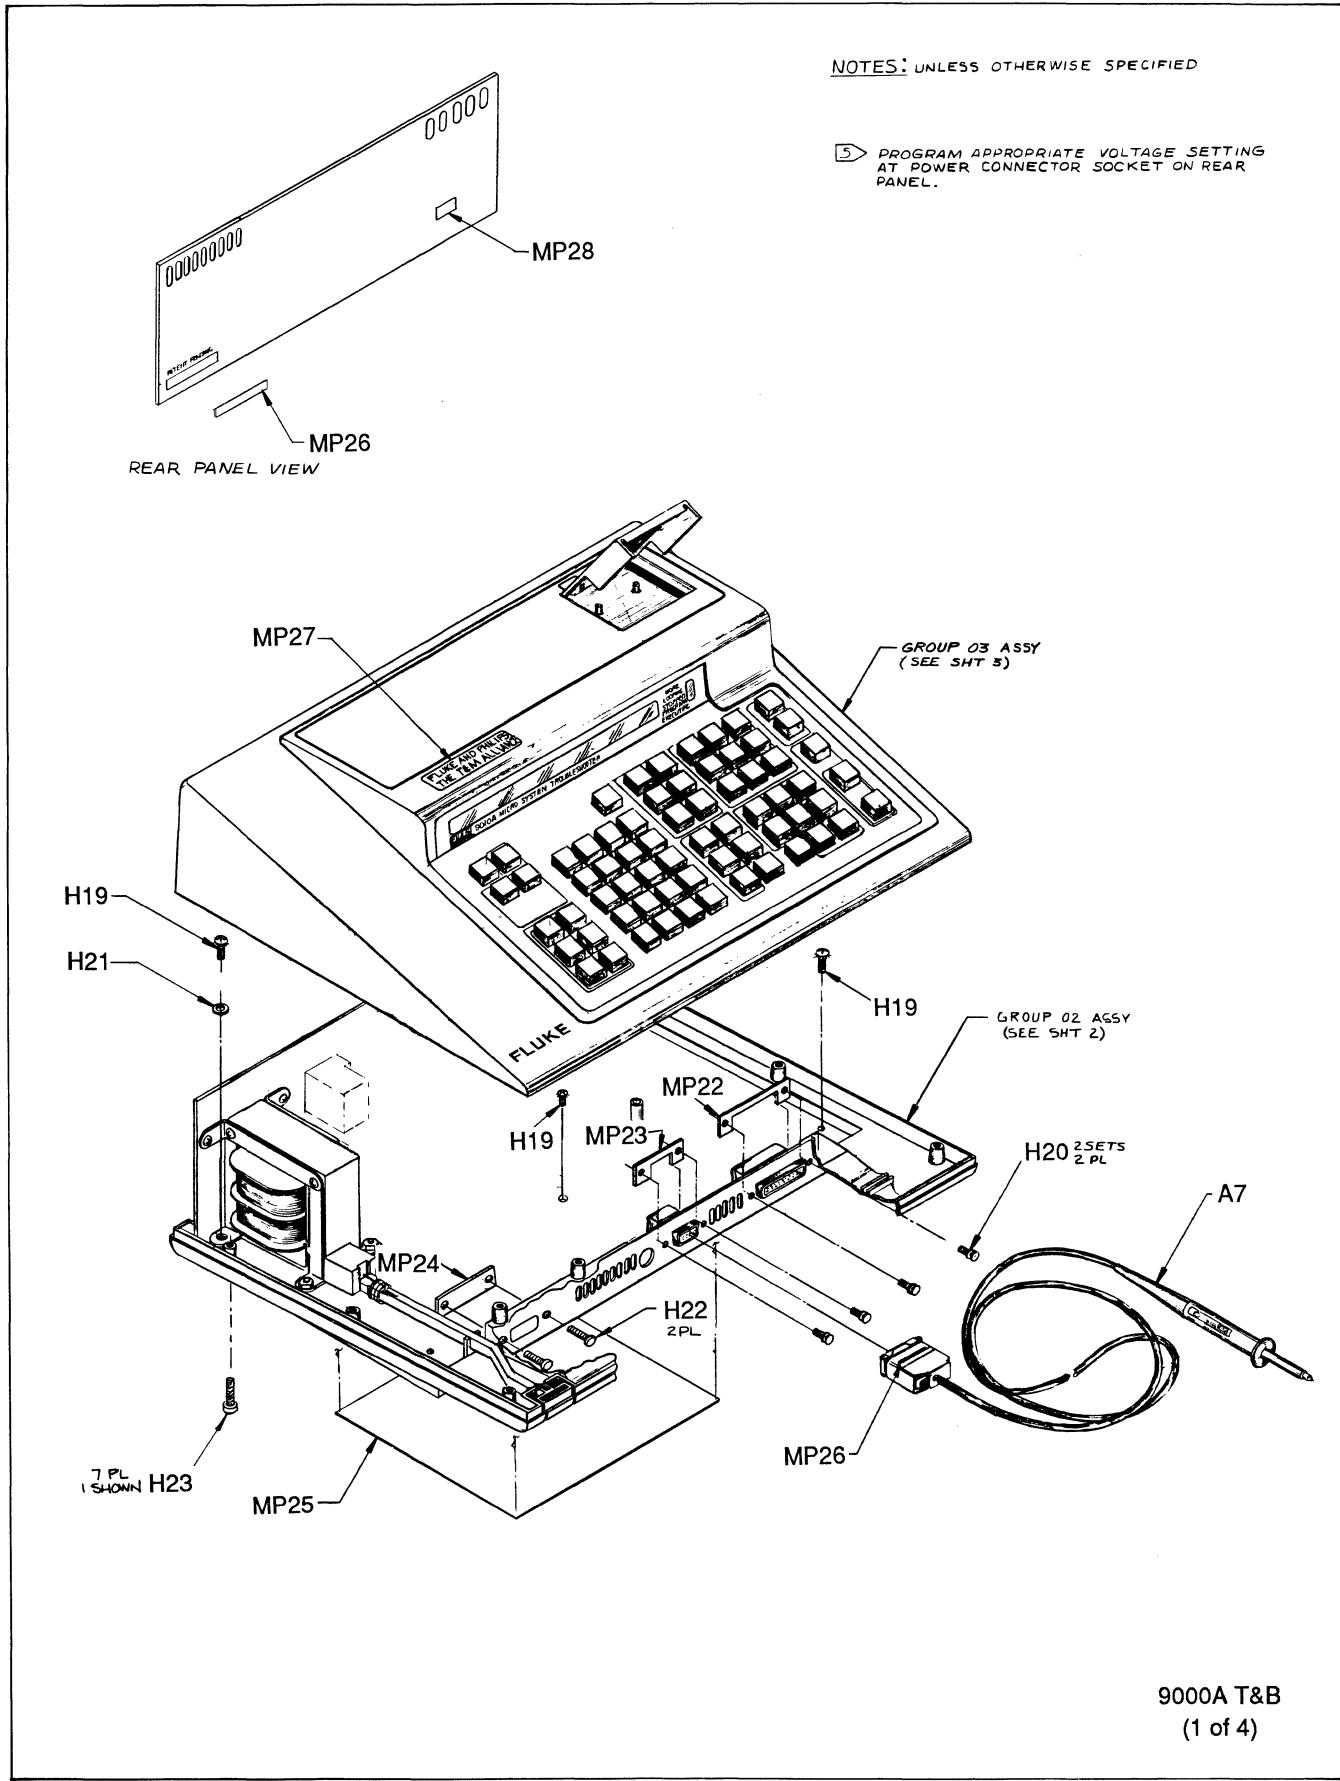

Figure 5-1. Final Assembly

**CAUTION**  
 SUBJECT TO DAMAGE BY  
 STATIC ELECTRICITY

NOTES : UNLESS OTHERWISE NOTED

- [5] FUSE & FUSE CAP VARY DEPENDING ON VOLTAGE UNIT IS PROGRAMMED FOR. SEE TABLE I FOR FUSE & CAP PART NUMBERS.
- [9] PROGRAM APPROPRIATE LINE VOLTAGE PER DETAIL III.
- [10] LOCATE & SOLDER TRANSFORMER (T1) PRIMARY LEADS TO PCB PER TABLE II BELOW.

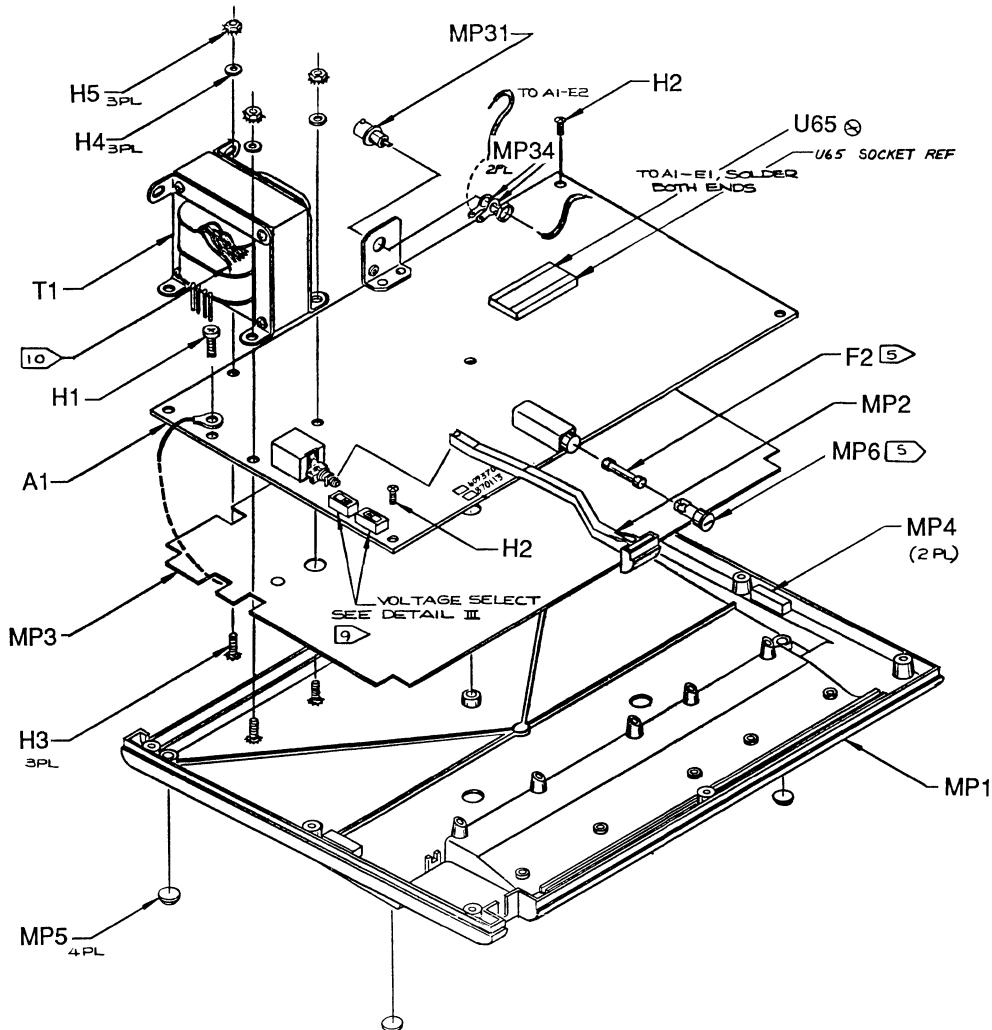

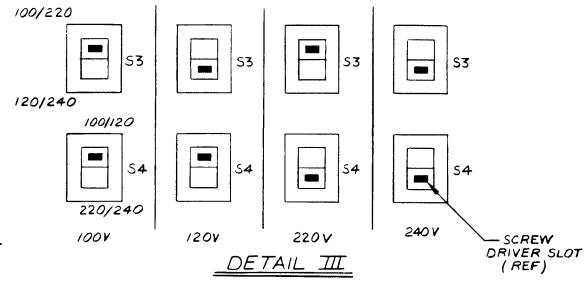

TABLE I		
VOLTAGE	ITEM MP6	ITEM F2
100 / 120	460238 FUSE CAP	109314 FUSE 1/4 A
220 / 240	461020 FUSE CAP	543504 FUSE 5X20MM 1/4 A

XFMR PRIMARY LEAD COLOR	SOLDER TO MAIN PCB CONNECTION
ORN	E4
ORN	E5
VIO	E6
BLU	E7
BLK	E8
GREY	E9
BRN	E10

**WARNING:** INDICATES USAGE OF MOS DEVICE(S)  
 WHICH MAY BE DAMAGED BY STATIC DISCHARGE. USE SPECIAL  
 HANDLING PER S.O.P. 18.1

9000A T&B  
(2 of 4)

Figure 5-1. Final Assembly (cont)

## **Section 6**

# **Option & Accessory Information**

### **TABLE OF CONTENTS**

OPTION/ MODEL NO.	DESCRIPTION	PAGE
-001	RS-232 Interface .....	001-1

### **6-1. INTRODUCTION**

6-2. This section of the manual contains information concerning the options and accessories available for use with the Model 9010A Micro System Troubleshooter. It consists of an introductory section, an accessory section, and an option subsection.

### **6-3. ACCESSORIES**

6-4. The accessories are fully documented in the Accessories subsection of the 9010A Operator Manual.

### **6-5. OPTIONS**

6-6. Each option is documented in an individual subsection of this manual section. Each option subsection includes all maintenance information for the specific

option: theory of operation, calibration, general maintenance, performance test, troubleshooting, parts list, and schematics.

6-7. Unique page and paragraph numbering, which corresponds to the option number, facilities subsection location. For example, a page numbered 001-1 is the first page of information for Option -001. A paragraph numbered 001-1 is the first paragraph concerning Option 001.

6-8. Subsections for options available at the time of this printing are included in this manual. Additional options will be available in the future. Contact your nearest Fluke sales representative for a current list of available options.

# Option -001

## RS-232 Interface

### **001-1. INTRODUCTION**

001-2. Option -001 is an RS-232 Interface which consists of a printed circuit board assembly mounted on the 9010A Main Assembly, and a standard RS-232 connector mounted on the 9010A rear panel. The RS-232 Interface allows the 9010A to communicate with remote devices, such as a printer, a computer, or another 9010A via the rear panel connector. Data transmission is asynchronous, with operator-selectable baud rates, seven or eight data bits, one or two stop bits, and selectable odd, even or no parity. Refer to the 9010A Operator Manual for connection and operating details.

### **001-3. THEORY OF OPERATION**

#### **001-4. UART Control**

001-5. The RS-232 Interface (Option -001) provides a standard communications interface port. The interface contains a **UART** (universal asynchronous receiver/transmitter) which performs the necessary parallel-to-serial and serial-to-parallel data conversion, and inserts stop bits and parity coding. Figure 001-1 shows that the data input lines (T0-T7) are connected via tri-state buffer U7 to the data bus. This buffer is constantly enabled. The status output lines: parity error (PE); framing error (FE); overrun error (DE); data received (DR); transmit buffer empty (TBE); and transmit register empty (TRE) are all buffered to the data bus via tri-state buffer U8. In addition to the six status lines, U8 always sends the upper bit (b7) low and the next bit (b6) high when a read status is performed. These two bits are used by the main microprocessor to detect the presence of the option card. The data output lines, and the status output lines of the **UART**, U1, are all connected to the microprocessor data bus, D0 - D7.

001-6. The microprocessor selects/addresses **UART** functions by means of the **I/O7** output of the I/O selector (described in Section 3) in conjunction with address lines A0 and A1, and the **WR** (write) line. To read the **UART**

status on six lines (D0-D5) of the data bus, the microprocessor makes address line A0 low, and **I/O7** low, which enables U8 to place status on the bus. The **UART** reset line is tied to the mainframe Reset line via U4. In addition the **DR** (Data Received) line is tied via U4 to **INT** (interrupt) line for use in the 9020 mainframe only.

#### **NOTE**

*Refer to Table 001-1 for a list of addressing protocol for the RS-232 Interface Assembly.*

001-7. The **TBRL** (transit buffer register load) input of the **UART** is made low whenever the microprocessor issues a **WR** (write) and the **I/O7** line is low. A low **TBRL** input loads the data byte present on the data input lines T0-T7 into the transmit buffer of the **UART**. The **UART** then transmits the byte in serial fashion via the **TRO** (transmitter register output) output.

001-8. The **RRD** (receiver register disable) input of the **UART** is held high by a high A1 address line whenever the microprocessor performs a write to the **UART**, or when the **I/O7** line is high. The high **RRD** input holds the **UART** data outputs (R0-R7) (to the data bus) in the high impedance state, allowing the **UART** data inputs (via U7) to accept write data placed on the data bus by the microprocessor or to be off when no **UART** transactions are taking place.

001-9. The **DRR** (data register reset) input of the **UART** is made low by a low A1 address line and a low **I/O7** whenever the microprocessor performs a read from the **UART**. The low **DRR** input notifies the **UART** that a read by the microprocessor has been performed. The **UART** resets its receive data register (connected to the data bus) and loads it with the next byte of serial data received via the **RRI** (receive register input) input.

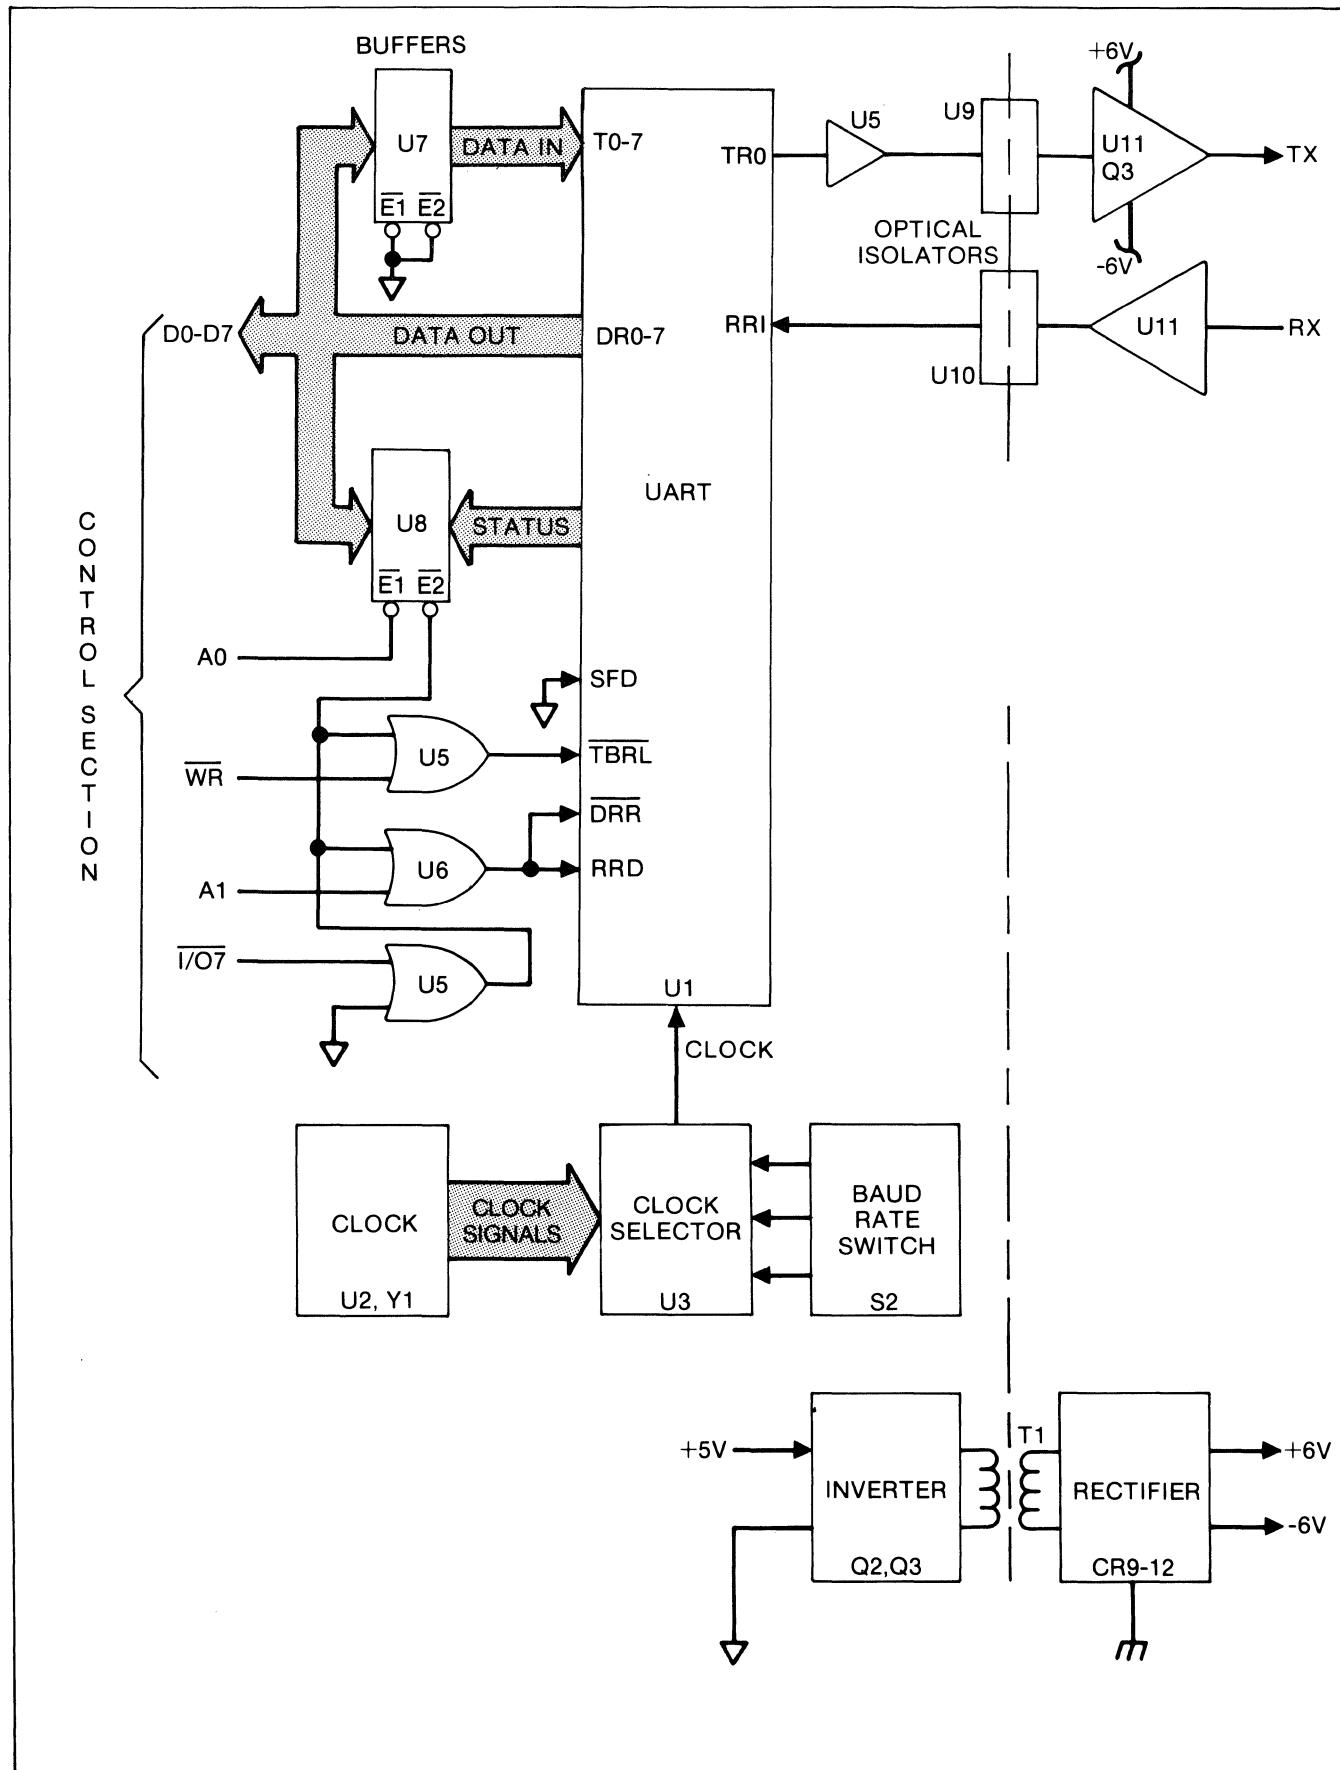

Figure 001-1. RS-232 Interface

**Table 001-1. RS-232 Interface Protocol**

ADDRESS	DATA	WRITE/READ	FUNCTION PERFORMED
100E1	Any	Read	Reads data received by the interface.
100E3	Any	Write	Writes data to be transmitted by the interface.
100E2	bbbbbbbb (binary)	Read	Causes the interface to respond with a bbbbbbbb status byte as follows:  bbbbbbbb xxxxxx1 = Parity error xxxxxx1x = Framing error xxxxx1xx = Overrun error xxxx1xxx = Data received xxx1xxxx = Transmit buffer empty

**001-10. UART Clock**

001-11. Clock generator U2, in conjunction with crystal Y1, provides an array of clock signals required for operation at baud rates of 110 to 9600. Clock selector U3 receives all clock signals and, under control of the baud rate switch S2, connects the required clock signal to the UART. The clock signal into the UART is 16 times the selected baud rate. Switch S1 is used to select parity (PI), 1 or 2 stop bits (SBS), 7 or 8 bit communication (CLS1), and even or odd parity (EPE).

**001-12. Line Driver/Receiver**

001-13. Driver U5 feeds the serial output of the UART to optical isolator U9. The optical isolator provides a guard crossing to the line driver made up of Q3, U11 and associated components. The line driver utilizes +6 volt and -6 volt supplies to provide +6V and -6V output levels to meet RS-232 signal requirements. The line driver output connects to the TX (transmit) line of the RS-232 connector.

001-14. The RX (receive) line of the RS-232 connector connects to the line receiver U11. The line receiver drives optical isolator U10 to cross the guard and apply received data to the RRI (receiver register in) input of the UART.

**001-15. Six-Volt Supply**

001-16. A +6 volt and -6 volt supply provides the power necessary for the line driver and line receiver to transmit and receive data under RS-232 requirements. The supply comprises an inverter, the output of which is transformer coupled across the guard to a full-wave rectifier. The rectifier provides filtered +6 volt and -6 volt outputs.

**001-17. Performance Checks**

001-18. To perform checks on the RS-232 interface, gain access to the PCB assembly by removing the seven cover-retaining screws, and removing the cover. The location of the RS-232 interface PCB assembly is shown in Figure 4-7. Proceed as follows:

1. Verify the correct signal period (and a 50% duty cycle) for each setting of the baud rate switch, S2, in accordance with Table 001-2. Use an oscilloscope with a X10 probe connected to the clock input of the UART (universal asynchronous receiver/transmitter), pin 40 of U1 on the RS-232 interface PCB assembly.

**NOTE**

*The frequency and period of the clock signal at pin 21 of U2 is 1.8432 MHz and 543 nanoseconds respectively.*

2. Verify the presence of +6 volts across filter capacitor C5 and -6 volts across filter capacitor C4, both on the RS-232 Interface PCB Assembly.
3. Verify the proper operation of the RS-232 Interface by performing the following:
  - a. Disable the watchdog timer (U31 on the main assembly) by jumpering C16/R14 to TP12 (ground). This removes the reset input from the RS-232 interface assembly and allows it to operate.
  - b. Jumper pins 2 and 3 of the RS-232 connector to loop the transmit line back to the receive line.
  - c. Key-in programs 8, 7, 12, 13, and 16 listed in Table 001-3 and execute program 8. The programs writes and reads data while verifying accuracy and correct status reporting.

001-19. If any of the performance or program checks fail, proceed as follows:

1. Swap the UART (U1) with a known-good device and rerun the program.

**Table 001-2. Clock Signal Frequencies and Periods**

SWITCH (S2) SETTING	BAUD RATE	FREQUENCY	PERIOD (APPROX)
0,8	110	1760 Hz	568 $\mu$ s
1,9	150	2400 Hz	417 $\mu$ s
2	300	4800 Hz	208 $\mu$ s
3	600	9600 Hz	104 $\mu$ s
4	1200	19.2 kHz	52 $\mu$ s
5	2400	38.4 kHz	26 $\mu$ s
6	4800	76.8 kHz	13 $\mu$ s
7	9600	153.6 kHz	6.5 $\mu$ s

2. Remove the jumper from pins 2 and 3 of the RS-232 connector. Jumper pins 20 and 25 of the UART (U1) to bypass the output buffers, isolators, and line receiver. Rerun the program; if the program passes, a problem is indicated in the output buffers, isolators, or line receiver.
3. Verify closures of parameter switches (S1) at pins 35, 36, 38, and 39 of the UART, U1 using the

tester 9010A probe in the free-running mode. Switches in the left (as viewed from the rear of the UUT) or open position should produce a logic high indication at the associated U1 pin. Refer to the schematic diagram contained in Section 8 for switch and UART pin relationships.

4. When prompted by the program, examine the opto-isolator circuits with an oscilloscope to verify that transmit data reaches the RS-232 connector at  $\pm$ 6-volt levels, and that received data reaches the UART (U1). Use signal ground (A5J2-5) for the common lead of the oscilloscope when checking at the RS-232C connector, and the 9010A ground when checking the UART.

#### 001-19. LIST OF REPLACEABLE PARTS

001-20. A list of replaceable parts for the RS-232 Interface is given in Table 001-4. Refer to Section 5 of this manual for ordering information.

#### CAUTION

## TECHNICAL SERVICE CENTERS

### U.S. Service Locations

**California**  
 Fluke Technical Center  
 16969 Von Karman Avenue  
 Suite 100  
 Irvine, CA 92714  
 Tel: (714) 863-9031

Fluke Technical Center  
 46610 Landing Parkway  
 Fremont, CA 94538  
 Tel: (415) 651-5112

**Colorado**  
 Fluke Technical Center  
 14180 East Evans Avenue  
 Aurora, CO 80014  
 Tel: (303) 695-1171

**Florida**  
 Fluke Technical Center  
 940 N. Fern Creek Avenue  
 Orlando, FL 32803  
 Tel: (407) 896-4881

**Illinois**  
 Fluke Technical Center  
 1150 W. Euclid Ave.  
 Palatine, IL 60067  
 Tel: (312) 705-0500

**Maryland**  
 Fluke Technical Center  
 5640 Fishers Lane  
 Rockville, MD 20852  
 Tel: (301) 770-1576

**New Jersey**  
 Fluke Technical Center  
 East 66 Midland Avenue  
 Paramus, NJ 07652-0930  
 Tel: (201) 599-9500

**Texas**  
 Fluke Technical Center  
 1801 Royal Lane, Suite 307  
 Dallas, TX 75229  
 Tel: (214) 869-2848

**Washington**  
 Fluke Technical Center  
 John Fluke Mfg. Co., Inc.
